HANDY ACCESSORIES IN A CENTRAL STATION.

To the casual observer it may seem that the duties of a central station engineer begin by lighting a fire in his boiler and end in sending out current to his customers; with the occasional use of the oil can on rods, levers, and bearings. Certainly to the uninitiated visitor to an electricity works these operations seem to be the principal aim of the men on duty. The chief engineer may have been partly responsible for this impression when he carelessly remarks "we put some coal in at one end and send electricity out at the other; a few drops of oil make things go smoothly, quite simple you see."

Just as there are moments when a policeman's life is not a happy one, so there are times when the apparently serene chief has his trials, and he is wise who has prepared himself, as far as possible, by every means in his power to meet all contingencies. To successfully supervise an electricity works one must be rich in resource and quick in cases of emergency.

A few handy tools or appliances in convenient and recognised places often save a lot of time and trouble. The ability to put things straight quickly when they have gone crooked is great, but the gift of "looking ahead" for causes which may develop into serious faults and cause disaster is much greater. Frequent testing of machinery and mains, examinations of engines and boilers, are all done with this primary object in view. The caulking of a boiler stay or seam, the tightening of a "big end," the adjustment of a piston or valve, the overhauling of a dynamo, the inspection of switch gear and connections, are each as necessary as the dropping of the oil in the aforesaid bearing.

It is sometimes very convenient to be able to make substantial temporary connections at the switchboard promptly, and these connections can be utilised for a variety of purposes, for instance, an engine may get on the dead centre; a little current turned into the generator would materially assist in getting over the difficulty. It may be advisable to take current from the switchboard for many purposes, and unless some means is provided it becomes a tedious and hazardous job to connect cable to the terminals or connections. Nothing can be more convenient than to attach to each end of a short length of flexible cable a dummy switch connection cut from a sheet of copper. This switch blade should have a projection to which an insulated handle could be fixed, and a second projection placed at right-angles to handle, to which the flexible cable is securely soldered.

The switch blade should be the same thickness as the real one, otherwise the jaws of the switch would be spread and the good contact of the switch destroyed. It is not difficult to see that a few of these devices will readily find a use. Some should have switch blades at each end, while others might have only one end so provided, the other being adapted to connect to the binding screw of a measuring instrument or similar device.

Our old friend the water rheostat is almost too well known to need mention. It is nearly as handy as a screwdriver or a pair of pliers, and will serve almost any purpose. For testing purposes it is invaluable. It is most useful used as a regulator when charging accumulators or testing arc lamps, shunting circuit breakers, operating motors for temporary purposes or supplying a load for dynamo and motor testing, temporary loads for synchronising, and many similar uses.

If, for example, it were desirable to rotate one of the machines as a motor, if the main switches consisted of two single-pole switches as they should, it would be the simplest matter to bridge one of the switch jaws with the rheostat by means of a pair of flexible connections as above described. The current could be varied at pleasure by manipulating the rheostat. Indeed, without this device or its equivalent the operation would be impossible.

An oil barrel, after cleansing, forms a cheap and convenient vessel in which to place the plates and liquid. A metal plate fixed to the bottom of the barrel, and a similar plate suspended in the barrel forms the simplest arrangement. From each of these plates must be taken a cable, that from the fixed plate may pass through the bottom of the barrel a suitable watertight joint being made to prevent leakage of the liquid. The suspended plate should be hung by the conductor, so that in case of a fracture the circuit would be automatically broken and all danger of a short circuit removed. As an additional safeguard two strips of insulating material about one inch in thickness should be placed permanently on the top side of the fixed plate. This would prevent the plates touching should the suspending conductor be slackened out too much by accident. It is well to have this apparatus placed outside, as the boiling and bubbling causes offensive fumes. It is easy to lead the suspending cable over pulleys to a convenient spot, preferably near the switchboard, when a small arc lamp winch can be utilised for raising or lowering the plate as required. A little sulphuric acid added to the water lowers its resistance and allows more current to pass. The exact amount of acidulation is best determined experimentally.

A rheostat constructed on these general lines will be found very useful and will facilitate many operations, which without such a device would be laborious and unsatisfactory.

STARTERS FOR GAS ENGINES.

By W. H. BOOTH.

THE gas engine, though a more efficient machine than the steam engine, has yet many countervailing disadvantages, which have been a great hindrance to its progress and popularity. Some of these are perhaps inherent to its principle; others are not. One of the difficulties with a gas engine is that of starting. A steam engine will usually start when the crank is off the centre and the cylinder is warm; the fly-wheel will carry the crank past the next centre and movement will continue. Not so with the gas engine. In its smaller sizes it is easy to start when in order, because the attendant can pull the fly-wheel round sufficiently to secure a first explosion, or even help it to the second explosion. But a man unaided is not able to start a gas engine of even moderate power. Gas engine makers have overcome this difficulty by the use of starting devices. These are various, ranging from a store of compressed air pumped up by the engine itself on previous runs, or a hand-pumping device to fill the cylinder and exploding by the timing valve, to various other contrivances more or less simple, and suitable for engines of moderate dimensions. But for large engines there is good reason to doubt the convenience and desirableness of these self-starters, especially of that order which depends upon a stored pressure of air pumped up by the last run of the engine. It seems to the writer that gas engine makers have striven too much after originality, and rather neglected well established and sound precedent. Until a comparatively recent date, factory engines were never provided with any kind of starting or moving gear, other than the ordinary rack and bar. Engines in pairs were, of course, self-starting, in so far as they were as a rule arranged with cranks at 90°, an old fashioned arrangement, by the way, which has ceased to secure universal approbation, more especially with compound engines, in the steam distribution of which, the 90° arrangement is apt to introduce an undesirable element. With the introduction of rope gearing, however, and the growth of the average pair of engines from 500 to 1,000 or 1,200 I.H.P., the old barring arrangement ceased to be practicable.

If only to facilitate the putting on of the ropes when the engines were first started or of new ropes as required, some more powerful means of revolving an engine slowly became necessary, and this was found in the small barring engine, a little pair of engines as a rule which were so arranged to gear into an internal toothed ring within the rim of the large rope-drum, that, when the main engines began to run with their own cylinders, the little engine was automatically thrown out of gear by the over-running of the large wheel. Every maker of large steam engines applies these small engines, and a large pair of engines is not considered complete without its small barring engine. Here is the complete precedent for the starting of the large powered gas engine. A gas engine, very small compared with the size of the main engine, will be of ample power to turn the large engine slowly round so as to draw in and compress its charge of gas and air and give the first explosion. Such small engines do not even require to be of a particularly economical type. They are required to be themselves set in motion by hand, and to render this easier, the compression may be kept moderate and less dilute mixtures of gas and air be employed. A run of a minute or two is all that is required to turn the main engine to the ignition point. It is not even always necessary that the starting engine should be able to exert a power sufficient to compress the charge in the main cylinder, for the main engine, once set revolving, will have a store of fly-wheel energy to assist this if gas admission be delayed, and the exhaust be kept open until the fly-wheel has acquired its maximum desired starting velocity. This system of starting has the advantage that the fly-wheel being in motion the stress upon the crank and other parts will not be so severe as when a first powerful explosion operates upon a piston at rest. For this reason it is well that the starting engine should not be unnecessarily small. The more quickly it is able to revolve the main engine the less will be the stresses put upon this. As with its prototype, the steam barring engine, so the gas starter may be arranged to throw out of gear when the main engine accelerates under its own energy, and the throwing-out gear may be coupled with a shut off valve to stop the gas supply, so that the little engine ceases to move as soon as it has fulfilled its duty.

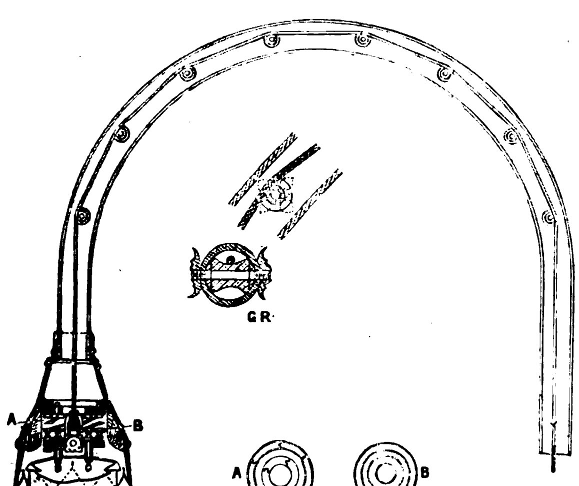
In a central station with numerous engines in line, an obvious method of starting is by a shaft extending the length of the line of engines, and operated by an electric motor or a small gas engine, or an engine may be started by its own dynamo, which supposes, however, a source of electricity. In single engines and on ordinary work, the small gas engine seems to present itself as the most satisfactory method to adopt. Where poor gas is employed, and mis-fires are likely to occur at starting, the use of a starter of the stored pressure type might prove exceedingly inconvenient should the store of air be used before a start were effected. With the barring engine the main engine can be simply kept moving until a fair start is secured. Failures to start may occur, with starting systems involving a pressure in the cylinder, by leakage past the piston. This is not likely to occur with a continuously revolving engine, as the loss of pressure is but slow though sufficient to render ineffectual all attempts to start an engine from rest.

Up to the present, gas engines have been chiefly employed in their larger sizes for producing electric current. Their initial duty is simply the acceleration of the fly-wheel; further duty only comes upon them after they are running. Put to perform all the work that is now performed by steam engines, other difficulties, hitherto not encountered, would be met with, notably, the necessity if roped direct to line shafts, of starting under an almost full load. The piece-workers of textile factories put the belts upon the fast pulley of the machines almost at once, and a steam engine has to start against a very large resistance. It seems probable that the future large gas engine for this class of work will require to be slip-coupled either to its driving pulley or by means of friction couplings on the driven pulleys so as to permit of speed being attained before resistance is put in. Possibly before this necessity arises all our factories will be electrically driven, as they should be, from distant sources.

HOISTING GEAR FOR STREET LAMPS.

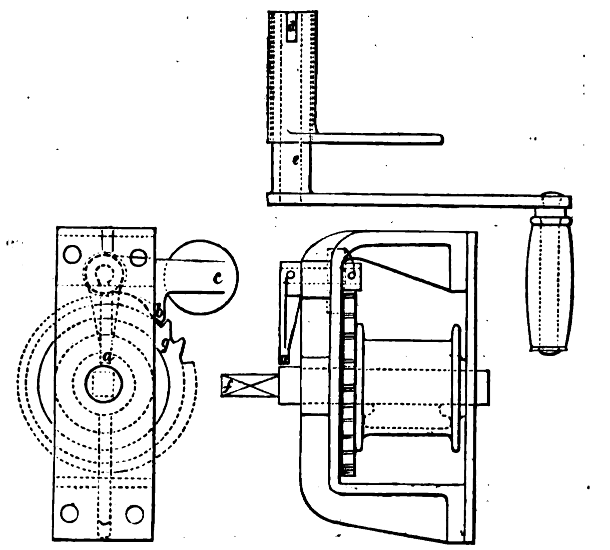
A somewhat interesting arrangement has been devised by Messrs. W. J. Davy and G. Thomas Davies, for lowering and raising street arc lamps. Primarily it consists of a winch placed in the base of a lamp-post, which can be operated by means of a handle without opening the door of the lamp column.

Some 10 months ago an arc lamp, post and gear, fitted with this hoisting arrangement, was supplied to the Bath Corporation, and although it was the first of its kind, it has, we believe, worked without a hitch, and the contacts are as



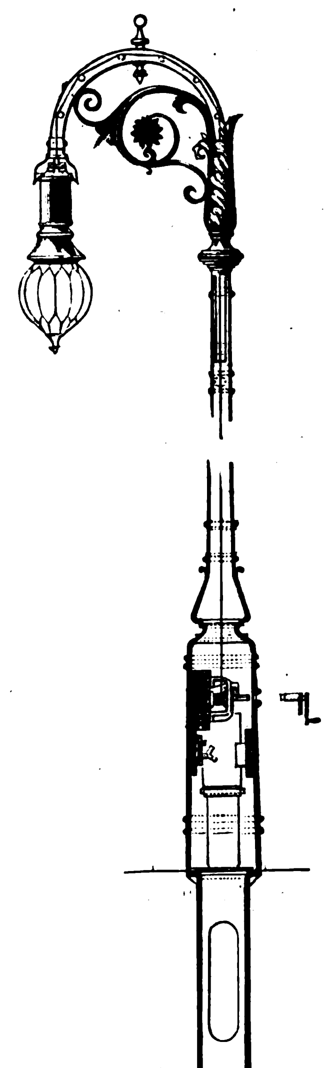
R, Guide rollers; A, Plan of contact springs; B Plan of contacts.
General Arrangement of Winch and Handle.

good, electrically and mechanically, as when first supplied. The means of making electrical connection are shown in the detail drawings. Two discs of porcelain or stoneware are separately mounted, the one on the top of the lamp, and the other inside the hood of the post. Upon these discs are fixed two insulated concentric rings of brass. The disc on the lamp has rings with plain surfaces, and they are connected to the terminals inside the lamp. The disc in the hood carries rings, to which are fixed a number of phosphor bronze helical springs, similar to a multi-threaded screw, in their arrangement. These springs are so arranged that they are right and left handed, and have a range of from $1\frac{1}{2}$ inches to 2 inches for compression. When the lamp is



General Arrangement of Hoisting Gear and Contacts.

hoisted into place the springs rub upon the plain surfaces of the concentric brass rings on the head of the lamp and rub in opposite directions, thus ensuring good contact.



Arc Lamp and Post fitted with Hoisting Gear.

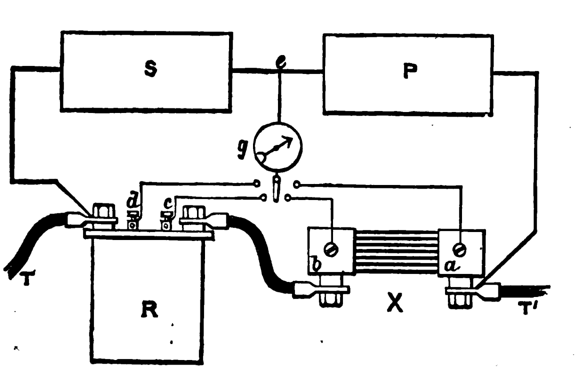
The lamp is guided centrally, first by the flexible steel rope passing between suitable guides centrally between the discs of porcelain, and, secondly, the head of the lamp rides between hard wood blocks in the hood, so arranged that the lamp remains in a fairly rigid position when in place. Even in a heavy gale the contacts are stated to show no sparking, and the surfaces are as smooth as glass. The cables pass around the bracket tube beneath the wire rope rollers, and are then fixed to their respective terminal sockets on the concentric brass rings. The Bath lamp-post was fitted with transformer, switches, and fuses, and worked off a 2,000 volts primary circuit to 50 volts on the secondary.

The winch is designed with a tail on the pawl spindle, and the handle has a loose sleeve. This sleeve has a notch in its end which can engage the tail on the pawl spindle. The vent-hole in the post just allows the handle to pass into the winch chamber. When the handle is shipped upon the spindle of the winch barrel, the small handle is pushed in to engage the tail, and by turning the handle slightly, the pawl is thrown out, and the lamp may then be lowered. It is impossible for anyone to lower the lamp with an ordinary handle without opening the door.

THE PRECISE COMPARISON OF VERY SMALL RESISTANCES.

A METHOD of measuring very small resistances, devised by Messrs. Alfred E. Muller and Herman Wallau, is described by Mr. S. Sheldon in a recent number of the *Electrical World*. The method is as follows:—

The unknown resistance, X, which may be assumed to be supplied with branch potential points *a b*, is connected by heavy conductors in series with a standard branch resistance, R, of the Reichsanstalt pattern having potential points, *c d*. From the two free terminals, T T′, of these resistances are shunted two 10,000 ohm resistance boxes, S P, adjusted to the same normal temperature and wound with wire of the same or negligible temperature coefficient, and connected in series. From the point of connection, *e*, between the two boxes connection is made to one terminal of the galvanometer, *g*, the other terminal being connected successively with the



potential points *a*, *b*, *c* and *d*. At the outset all the plugs are removed from the box S, and all are in place in the box P. After connecting T and T′ with a source of heavy current, plugs are transferred from one box to the corresponding holes in the other box (this keeps the total resistance in the two boxes constant) until no deflection is observed in the galvanometer. This operation is repeated for each of the potential points *a*, *b*, *c* and *d*. Representing the resistances in the box S, on the occasion of each of these balances by S_a, S_b, S_c, and S_d, respectively, we have the following expression for the value of the unknown resistance:

$$X = \frac{S_a - S_b}{S_c - S_d} R.$$

This method serves also to determine the resistance of a storage cell when the terminals, T and T′, are connected to a source of alternating currents, and when a telephone is substituted for the galvanometer. It is probable that by employing an electro-dynamometer instead of the galvanometer, whose fixed coil was connected to the main circuit before it reached the terminal T, according to the method recently advocated by Prof. Rowland, the resistance of an accumulator could be determined with extreme accuracy.

THE COST OF GENERATION AND DISTRIBUTION OF ELECTRICAL ENERGY.

(*Continued from page* 432.)

WE now come to what Mr. Hammond has made the main subject of his paper, viz., the summarising and analysing of the works' costs and costs of management of all the existing electric supply undertakings which are operating under the Electric Lighting Acts, and the deductions which may be made from the great mass of statistics which have been tabulated. Tables are published of the costs per unit sold for each undertaking from 1890, or from the time of starting if later than that date, down to 1896 and, in some cases, 1897; other tables show for each item of the costs the order of merit of these undertakings for the years 1894 to 1896 inclusive, and also the record costs for the same three years in stations of various outputs; and, finally, there are tables giving the load factor and the proportion of the units generated which were sold, used on the works or in distribution. These tables contain a very large amount of useful information, and from them the author of the paper makes various deductions, referring in turn to each of the factors which are of importance as affecting the cost of production, and discussing the probabilities of reaching costs as low as those which result from combining in one works the record costs obtained for each item in any of the undertakings, or as the ideal costs given by Mr. Crompton in his 1894 paper.

In discussing the conditions which tend to produce low costs, Mr. Hammond gives to output the credit of being the most important factor in the reduction of the cost per unit, and assigns the second place only to load factor, stating as his reason that without a good output the most favourable load factor is useless. In this we are quite unable to agree with him, and, although we fully recognise the advantages of having a large output, we think that the tables published by Mr. Hammond show clearly that he has overestimated these advantages; and that if a good load factor needs the help of a large output, this latter is even more in need of the good load factor, if we are ever to approach the ideal figures mentioned in the paper. It is quite true that an examination of the figures for successive years of any individual undertaking shows that, almost without exception, an increased output has been accompanied by a lower cost; but it by no means follows that the increase of output is of itself the prime cause of this reduction, as during the early years of any new undertakings we may reasonably expect that improvements in the plant and in the methods of working will continually be made. To take an example from the costs quoted by Mr. Hammond, we find that the output of the Westminster Company in 1893 was 1,704,615 units, and in 1897 it had increased to 4,855,781 units, and that in this latter year the works' cost per unit was only 57 per cent., and the total cost 63½ per cent. of the corresponding costs in the earlier year. We also find that the output of the Edinburgh works in 1896 was 1,721,557 units, or practically the same as the Westminster 1893 output; but can we expect that if this output is increased to say 4½ million units there will be a similar percentage reduction in the costs? If so, we shall have to congratulate the management on having arrived at a works' cost of ·361. and a total cost of ·72d. per unit, which seems too good to be true; and we think it is fairer to assume that the Edinburgh works, which started some four years later than those at Westminster, have benefited by the experience gained during that time, and were able therefore to start with costs much nearer the ultimate minimum than was the case with the older undertaking.

An examination of the tables shows also that many works with comparatively small outputs hold a very good place in the order of merit; and that if we take the average of the costs of all works for every year in which their output has been more than a 1,000,000 units, these average costs are not very high up in the order of merit. The actual figures are, for fuel ·882d., for oil, &c., ·155d., for wages ·560d., for repairs ·410d., for works' costs 2·007d., and for total cost 2·876d.; or excluding from the list the works using the alternating current system, we get, for fuel, ·676d., for oil, &c., ·118d., for wages ·505d., for repairs ·382d., for works' costs 1·681d., and for total cost 2·522d.

One point which strikes us as especially worthy of notice in comparing the costs per unit sold of any one undertaking in successive years, is that, although in most cases substantially lower costs of fuel, stores and wages are obtained with an increase of output, the cost of repairs and maintenance shows no such regular diminution; and that in the items of rent, rates, taxes and management, which we have been accustomed to treat rather as fixed charges and where we should, therefore, expect the largest decrease, we find that the cost per unit decreases more slowly than the works' cost, and in many cases even shows an increase. For example, at Bradford, although the first seven years' accounts show an increase of output which is nearly eight-fold, the costs per unit of rent, rates, taxes and management are respectively ·94d., ·61d., ·38d., ·42d., ·52d., ·76d. and ·78d. for these seven years; and at Glasgow, with a five-fold increase from 1892 to 1896, the costs of these items for the five years are respectively ·84d., ·71d., ·78d., ·82d. and ·60d. With companies we find a similar state of affairs, as the City of London Company with a ten-fold increase of output in five years has actually increased the cost of these items from ·97d. in the first to 1·50d. in the fifth year; the Metropolitan Company, whilst increasing its output from 1½ to 4 million units, has spent the same amount per unit on these items in the first and last years under consideration; the St. James's Company spent 1·17d. per unit when their output was 1,000,000 units, and ·92d. per unit with an output of 3,000,000; and the Westminster Company, who spent 1·99d. per unit in its first year with an output of 600,000 units, steadily reduced this to ·80d. in its fifth year with an output of 2,800,000 units, but increased it to ·85d. in its sixth year, and to ·90d. in its seventh year with an output of over 4,000,000 units.

It would appear, therefore, that mere increase of output, though having no doubt a good effect on the costs, does not influence them to the extent we might expect from Mr. Hammond's statement; and this is especially the case in those items that are frequently spoken of as fixed charges. If we now consider the effect of an improved load factor, we find that Mr. Hammond gives a table showing the reduction of costs that might be expected at Bristol, if those works were blessed with a load factor of 50 per cent. instead of the 12·99 per cent. which was the load factor for 1896. From this table we find that he estimates that with the same maximum demand in both cases, the four-fold increase of the load factor would reduce the total costs from 2·50d. to 1·00d., a reduction of 60 per cent.; but in the table of costs of various undertakings in successive years we look in vain for any instance of a similar reduction due to a four-fold increase of output, except in the case of the comparison of an abnormal first year's working with that of a subsequent year. It may, of course, be said that Bristol is a favourable case for a considerable reduction, as an improved load factor would naturally have a greater effect on an alternating current transformer system than on a direct current system, owing to the importance of the transformer losses at low load factors, and also because the 1896 consumption at Bristol of 16 lbs. of fuel per unit sold would appear to offer a considerable margin for reduction.

Even if this be so, and the reduction of cost estimated by Mr. Hammond for this particular case be larger than could be effected in other works, a consideration of the conditions under which a four-fold output is obtained (1) by improved load factor without increase of maximum demand, and (2) by increased maximum demand without change of load factor, will at once show that the reduction of cost in the former case should be immensely greater than in the latter. In the first case the increased efficiency of the plant owing to the better average load and the relatively smaller stand-by losses in the boilers will make a considerable reduction in the coal bill; whereas in the second case the larger output will not make much difference in the average output of the machines, and as the number of boilers under steam at the time of maximum load will be increased in proportion to the demand, the stand-by losses will practically still bear the same proportion as before to the total fuel consumption. Again, in the first case, as there would be no increase in the number of boilers or machines to tend at the time of maximum demand, it would be unnecessary to increase the number of men in the heavy shift, and any increase in the wages bill will be due chiefly to the small increase in the number of men that may be necessary in the day time; whereas in the second case, at the time of maximum demand, boilers and machines of four times the output will be at work, and at all hours of the day the number of boilers and machines in service will be increased in much the same proportion, so that the labour bill will be considerably augmented. The difference in the charges for repairs and management may not be very great in the two cases, but the balance would, we consider, be in favour of the good load factor; but the second case must certainly be debited with heavier charges for rent, rates and taxes, owing to the greater space occupied by the plant. Although it is not included by Mr. Hammond in his consideration of the question, one of the most important differences between the two cases would be that due to the items for interest and redemption; as, in the second case, the capital expenditure would have increased in proportion to the output, whereas in the first it would have remained practically stationary.

With regard to the third factor which tends to reduce costs, viz., reliability of plant, we agree with Mr. Hammond that too much stress cannot be laid on its importance, not only on account of the lower costs of repairs and maintenance which naturally result therefrom, but also because immunity from breakdowns and interruptions of service is absolutely essential to the success of any undertaking which depends on extending the use of electrical energy. This is so important, in our opinion, that we should always be prepared to sacrifice something in efficiency, if to obtain this latter it was necessary to diminish in the slightest degree the reliability of the plant; and we consider that any extra expenditure that may be necessary to ensure that spare boilers and generating plant shall always be ready at a moment's notice to be put into service is always justifiable, although it may make the cost per unit sold somewhat higher.

Mr. Hammond next refers to the engineer factor which has undoubtedly a very great influence on the cost of production, as a great deal of the reduction of costs shown in the tables in this paper is, in our opinion, due to the care and attention bestowed by the engineers on the details of th working of the plant under their care. It would be most interesting and instructive if we could get to know how much of the reduction of costs, attributed by Mr. Hammond to increased output, is really due to that cause, and how much should be credited to the engineer factor; and we hope that some of the engineers of central stations will be able in the course of the discussion to give us practical information concerning the methods of working which they have found most helpful to the reduction of costs, and tell us to what extent they have been able to reduce some of the losses which exist in all stations.

(*To be continued.*)

ELECTRIC HAULAGE ON RAILWAYS AND TRAMWAYS.

By W. H. BOOTH.

Surely, if slowly, electric traction is making headway in this very backward country. New tramways are rarely proposed, says the *Practical Engineer*, which are not intended to employ mechanical traction in some form, but as our contemporary remarks, engineers are looking to the conversion of existing horse tramways for a large amount of future work, and are endeavouring to secure concessions for such undertakings, but local authorities are often proving difficult to deal with, being apt to take an exaggerated view of their position, and to refuse to entertain proposals which must be to their benefit for fear someone will make a profit. The city of Bristol is quoted as an instance, having now on hand a controversy with the tramway company. Corporation officials have compiled figures which show a working expense per car mile very considerably below that of horse traction; electric traction being 5½d. as against 9½d. for horse traction. Electric traction is thus practicable, economical, and undoubtedly convenient.

The *Practical Engineer*, however, rather looks to the heavy equipment work of railways as affording the principal work for engineers as soon as, or before, all the tramways have been converted.

We do not ourselves look forward to the speedy ousting of the steam locomotive from main line work, but for short railways like the overhead line at Liverpool, electricity must come quickly. The Baltimore and Ohio tunnel is proof of the entire possibility of heavy work being done, while the bad condition of our own Underground seems to point to the speedy necessity of an electrical equipment, if only to save it from the bankruptcy so long courted.

Locomotive expenses on the Liverpool overhead line are stated to be under 3¾d. per mile, as compared with 6d. to 6½d. on ordinary railways, and 11d. on the Underground. Metropolitan locomotives weigh 46 tons 12 cwt., the following train weighs 90 tons. The horse-power is 380 on the level at 25 miles per hour, and to attain to a speed of 15 miles per hour, requires 30 seconds. There are 14 trains circulating on the 13 miles of the inner circle; seven trains on each line at 10 minutes intervals. A seven minutes' electrical service, with a seven minutes' interval only, is estimated to cost £350,000. If all this be looked on as new capital, its cost at 4 per cent. will be £14,000 annually, or, say, £40 a day. With 14 trains now making the 13 miles circle, the present daily train mileage of circle trains only is about 2,500. This does not include the extra trains to Gloucester Road and Kensington, &c. At a saving of 3d. per mile, the daily saving would be thus over £30, and would still leave 8d. per train mile for further reduction to the Liverpool figure of 3¾d. It is thus quite possible in locomotive expenses only to save all the interest on new capital, and we can scarcely doubt that the increase in receipts would be sufficient to pay a very satisfactory sum towards sinking fund and dividends.

Mr. Fox's proposal to use motor trains* (*of the Liverpool type*) for the circle working and electrical locomotives* (*South London system*) for trains coming in from outside seem reasonable and good. Considering what has been accomplished in America, it seems to us that Mr. Bell, of the Underground, is rather begging the question in raising so many objections and difficulties, and talking of *the* question to be solved being to provide sufficient electrical energy where required to do the duty demanded of it. We presume that when Mr. Bell wishes a train to start from the Mansion House, he provides a locomotive as a persuader, and another locomotive if a second train has to start at the same time from Blackfriars. If he wants to start electrical trains from anywhere, he will have to provide electrical energy to do so, as all other electrical railways have done. There would then be nothing to prevent these trains from moving, which seems to be the burden of his song to the shareholders. We do not think Mr. Bell need have troubled to go several times to America before being able to conclude that electricity would solve the ventilation question. If any journey to America were necessary, surely one by an engineer, and not by a managing director, would have sufficed.

What a shockingly poor opinion of his shareholders Mr. Bell seems to possess if his statements to the Parliamentary Committee and to his shareholders are correctly reported. The question of electrical traction is being looked at far too narrowly and with an ultra cautiousness. Americans have found that convenience, cleanliness, and rapidity of service and acceleration have made things pay. The same advantages would equally pay in England, if our railway managers understood their business.

* The bracketed remarks are not Mr. Fox's.

THE TELEPHONE SITUATION.

The discussion in the House of Commons on Friday evening last, and the decision expressed by Mr. Hanbury, were both based apparently upon the impression that "something must be done," which is very satisfactory, provided that the "something" is the right thing, and does not result from the anxiety to do the wrong thing rather than nothing at all. The appointment of another Select Committee, though open to the suggestion of a further shelving of responsibility, may, nevertheless, be regarded as a fairly satisfactory measure. It will avoid action in haste, and provide a tribunal before which facts may be laid, and their bearings accurately gauged. The re-opening of the telephone question at this stage is the result partially of public discontent, of which some is real, but much is unreal, because formed upon interested or incorrect information. We may take as an example the comments of our contemporary the *Economist*, which in its last week's issue stated that the telephone subscription in Berlin is £2 10s. per annum. There can be no possible doubt of the desire of our contemporary to improve the position of London business men, or of its anxiety to do so by the fairest possible statement of the facts. We should have regarded these figures as a misprint had we not ourselves received a statement in which they appear with, however, the qualification that there is a further charge for every call made. We have heard of instances in one of the "cheaply telephoned" countries of the Continent where a subscriber pays as much as £80 for one year's use of the telephone, although the subscription, as quoted by our contemporary, would be given as about £3. Telephone rates, like everything else, must be considered in the aggregate, and so considered, English rates are not excessive. Relying, again, on figures at hand in the Glasgow Report (p. 11), the Commissioner states that Mr. Gaine proved the cost of each message in Glasgow to be ·57d., or practically one halfpenny per message. In our report of the Glasgow inquiry, we showed from the evidence of several subscribers that the rate of subscription is not the cause of serious complaint. There was evidence there, and there is evidence in general that a good service is highly appreciated and willingly paid for. The reduction of rates, if it can be done upon a commercially sound basis, should be strenuously striven for; but the evidence as to its practicability is of the most flimsy character, and we are glad to note that Mr. Hanbury, although bearing in mind the advantages resulting from an extension of telephone service amongst small traders, did not in general hold out any useless hopes of reduction of rates, so as to imply a less payment by subscribers in the aggregate. Another consideration which needs to be borne in mind, is the mistake of drawing too wide conclusions from limited evidence. Mr. Hanbury recognises this by saying: "In a good many parts of the country there is not, so far as I know, very great complaint; but in several large towns, in Glasgow, and even the metropolis itself, complaints have been made of inefficient service, and in the case of Glasgow that complaint has been proved to be true by our own Commissioner."

It would have been fair to add the qualification made by the Commissioner, that the inefficiency was due to the dog-in-the-manger policy of the Corporation, although we cannot ourselves consider his qualification to explain the entire cause. We should be rather disposed to inquire in what respect the Glasgow system differs from that in use in other parts of the country, or why it is related by one witness that he used the telephone in Liverpool and New Zealand, and experienced none of the difficulties that existed in Glasgow.

In the words of the Commissioner: "The method of working the system at the exchange office is known as the 'call wire.'" It may be assumed that in introducing this system in Glasgow the Telephone Company were desirous of giving what they regarded as the best system for the purpose, but we are justified in recalling our own criticisms on the system, when the present electrical adviser of the Corporation proposed its introduction into London.

The persistent efforts which were made to set aside our conclusions will be in the recollection of some of our readers. We were informed with a view to a settlement of the prolonged controversy that the National Telephone Company had decided to introduce the system in Glasgow, and we remarked that we regarded its introduction there as an experiment, the success of which we should be glad to chronicle. It is impossible to read the evidence and report without observing the extent to which the adoption of this system is responsible for much of the discontent and many of the complaints, although the points were not emphasised by the electrical experts on either side. The Commissioner says: "If a number of people are impatient and all bawl through the call wire at once, great confusion and annoyance may be caused to the operator. But this need not exist if people deal with it in a businesslike way and give place to each other." This argument was used in our columns by advocates of the system, and the undesirability of relying upon it pointed out. The imperfections of the system had their bearing upon the result of the inquiry, though the Corporation in its desire to extend their municipal functions and, as they suppose, improve the communications of the inhabitants, would doubtless, under any circumstances, have made an effort to obtain municipal powers. It will be for the Select Committee *in futuro* to determine "whether it is fair that competition should be allowed to take place," and "whether the municipalities are the best form of competition." It would not have seemed to us out of place if these points had been preceded by one other, and that is, whether any competition is desirable. It is of more importance than the question of fairness. Existing agreements provide for competition either by companies or the Post Office. The introduction of a municipality in the place of the other defined competitors is not in itself unfair, but might readily become so if the municipality adopted the methods of the Glasgow Corporation, who seek to fetter its competitor by its municipal powers, whilst competing with it by the use of public funds. Neither the British public nor the British Parliament will, we think, permit one combatant to have the use of a mailed fist whilst the other combatant has his arms pinioned behind his back. It is sought by various specious means to discredit the Telephone Company, to suggest that its own proceedings justify otherwise unjustifiable methods. Reference is made to the maintenance of the monopoly by the purchase of competitors. The purchase of many of the undertakings referred to in the debate was nothing more than an amalgamation of family interests amongst whom there was no competition at all. The amalgamation was avowedly undertaken with a view to have the strength of a bundle rather than the weakness of a series of sticks. The only important extinction of a competitor in recent years was the purchase of the New Telephone Company.

Since we protested vigorously against the Treasury minute which made it possible to the new company to reap a harvest practically without sowing any seed; since we foretold the result which actually took place, we may recall our observations to the effect that the benefits would be greater under a monopoly than through competition. We have no hesitation in saying that by acting in self-defence, so as to exclude competition, the Telephone Company has acted in the best interests of telephone subscribers. Competition by the Post Office occupies a different category to any other. The Post Office has—what no municipality has, or, apparently, can get—the skill to do the work, and the right to undertake it. Such right has been reserved generally, and has been promised to be exercised specifically in cases of inefficient service. The case for the municipalities is probably understood by Mr. Benn as well as anybody. In his examination of Mr. Preece before the Select Committee of 1895, it was apparent that he was under the impression that a series of municipal plants would be of help to the Post Office in 1911. We hold it to be not so much a matter of doubt, but almost a certainty, that the reverse would be the case. The country would have to pay for the mistakes of localities, and the localities would have suffered serious inconvenience in the meantime. Competition by the Post Office itself, though to be regretted, may be necessary, and the circumstances under which it may become necessary, were clearly defined by Mr. Lamb before the same committee in his answer to Sir Charles Cameron's question, No. 5,261: "Of course, I do not know what may happen at that time (1911), but I should say the reasonable thing to happen would be this: that at a given date which would give the Post Office sufficient time to supply a system of its own in the event of the negotiations falling through, the Post Office would approach the National Telephone Company, and say: 'What is your price for your plant?' It would ascertain by examination whether it was in a fair condition, and if the National Telephone Company were reasonable, the Post Office would pay a reasonable price, and in my opinion, would be supported by public opinion in doing it. If, on the other hand, the National Telephone Company feeling secure, and thinking the Post Office could not supply itself in any other way, held out for unreasonable terms, the Post Office would immediately proceed to supply itself with another system, and as soon as the license expired, would be able to bring it into operation."

"By the (chairman): Or before?—Or before, if necessary. If the company was unreasonable?—Yes."

If Mr. Hanbury's statement be read in the light of this answer, its bearing will be apparent, and much of the pernicious nonsense which is talked and written about the relationship of the National Telephone Company and the Post Office will be seen to have no foundation. It is readily admitted by the most prominent agitators, that a Telephone Exchange system is at the very least a commercial necessity. By whom has this been demonstrated so far as the United Kingdom is concerned? By the adventurous men who embarked their capital and skill in the enterprise and obtained a charter of limited duration. The National Telephone Company are their successors in the direct line, and they are entitled to consideration for their acumen and the just reward for their venture. Their work is one which will be undertaken by the Post Office on the expiry of their license, and may be acquired earlier. The terms for such acquisition can best be settled to the advantage of the country by the high contracting parties. Meddlesome interference by others can only end in loss, and may produce disaster. Let Mr. Hanbury bear this in mind, and the promised Select Committee may be useful.

CORRESPONDENCE.

Supply Current for Electro-Plating.

Probably the simplest method and cheapest apparatus to construct to reduce the supply pressure would be to use a resistance of steel wire spirals. The objection to this is the

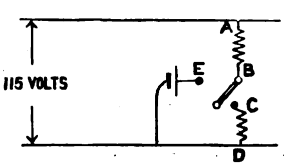


Fig. 1.

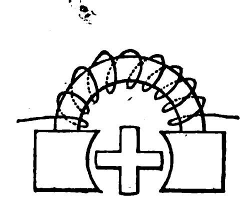

Fig. 2.

great waste in resistance heating, but perhaps this might be arranged, and serve the purpose of heating the room or adjacent room. Connect them as follows, fig. 1:—

Make A, B of 7·53 ohms value,
and C, D of ·14 " of wire capable of carrying 15 amperes without undue heating.

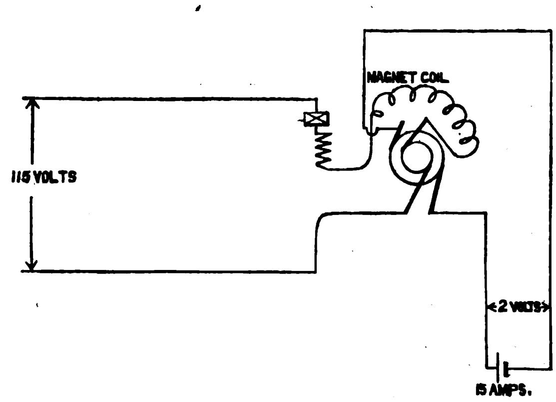

Fig. 3.

Connect B to C to warm the room,
" B to E to warm the room and electro-plate at same time.

The most economical method in working would be to employ a small continuous current transformer, which might be made on the lines of horse-shoe magnet and shuttle armature series machine, fig. 2, with four-part and eight-part commutators.

Let motor run between 2,000 and 3,000 revolutions per minute. Put in on one side (supply side) about 35 volts, 2 amperes, and take out about 2 volts, 15 amperes, fig. 3. Lose about 10 volts in magnet and 7 or so in armature. Wind about ¾ lb. of No. 22 on magnet, and ¼ lb. of No. 24 on armature for primary, and ¼ lb. of No. 18 on armature for secondary. Make a resistance to carry 2 amperes and of about 40 ohms, more or less according to voltage motor gives.

Of course, a secondary battery of 113 volts might be placed in opposition to 115 volts, but if a battery is available, it would be certainly used direct.

N. C. Woodfin.

P.S.—I don't think it is practicable to make such a small motor to work much above 30 volts, or even less than 2 × 80, or 160 watts would be wasted in dead resistance, whereas in previous method 1,695 watts or over 2 horse-power would be wasted.

Your correspondent, Mr. R. T. Dick, is evidently under the delusion that he is inviting the consideration of engineers to an original problem; I may, therefore, state for his benefit, and for that of the "others" he mentions, that his difficulty could in all probability be solved by the contractor he employs to wire his premises, certainly by the borough engineer.

However, as I have a few minutes to spare, and as I expect he will not hear from very many "eminent" engineers, I beg to offer my humble solution.

For a continuous current supply there are three possible methods:—

1. Have a battery of 55 cells, charge them in series, then do your plating with them in parallel.

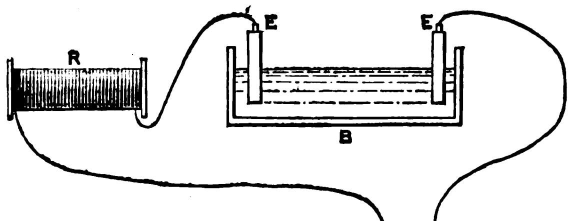
2. Use your 15 amperes at 115 volts and reduce the voltage by a liquid or wire resistance.

3. Procure a small motor generator, that is, a dynamo having two windings on the armature, one for 2 volts and the other for 115. This is by far the best and cheapest, besides being a continuous process.

You want, say, 15 amperes × 2 volts × 9 hours × 6 days = 1,620 watt-hours, say the efficiency of your machine were only 75 per cent. (but it would be more), then the watts required come out 2,160, say, 2 units per week, and the Brighton charge for power I think is 2d. = 4d. per week.

C. B. Nixon.

As the voltage of the supply mains has to have a drop of 113 volts it is only necessary to put a resistance of 7·5 ohms in series with the bath and the mains. The resistance of 15 ozs. of German silver wire of No. 18 B.W.G. is equal to



R, Reel with 7·5 ohms resistance; E E, Electrodes; B, Bath; S M, Supply mains, 115 volts.

7·5 ohms. This must be wound on a reel and each turn must be separated from one another, as per sketch, the reel to be a good insulator, and preferably covered with asbestos on account of the current heating the coil of wire.

J. S. Barnes.

Knots.

Seeing that the knot question is still vigorous, I should like—now that it has got away from its original lines—to add a few remarks in support of the telegraph engineer and electrician.

I venture to think there are many of us who, recognising that a knot is a *velocity*, have always preferred to use "N.M.," or "naut." in abbreviation for "nautical mile."

It appears to me that any importance that may be attached to such a matter applies more in particular to printed publications and especially text books.*

Presumably Mr. Little's remarks are mainly intended for the benefit of the student class and for academic circles; he surely does not aspire to make a fully equipped "cable" engineer change his method of expression!

Though it is improbable that the mis-use of the term "knot," as a measure of length, has ever given rise to confusion or actual misunderstanding, most of us will fully realise that all misapplications of terms are undesirable, if only on account of the future generation and for purposes of clear insight.

Considering that a knot signifies one nautical mile per hour, "knots *per hour*" is, of course, not only redundant but ridiculous. Nevertheless, it is an expression which is used every day—just as "knots" are for length—by many past-masters in matters nautical who do not, I presume, happen to have come at close quarters with the subject.

I am sorry that Mr. Little has marshalled forth some of the literature on the subject, for I fear it may only have the effect of extending a discussion—with doubtful profit—by a shower of quotations from Raper, Norie, Bedford, and other authorities.

Charles Bright.

Blasting.

An accident occurred at our works on February 24th last with electric blasting detonators, 25 of which exploded with violence, injuring one person, named George Joyner, contractor for mine sinking, he having to be taken to the hospital immediately, and there remained in a critical condition for three weeks. The detonators exploded with such violence that all the windows were blown out, and frightfully injuring the man's breast and hands, also causing him to lose his left eye. The cause of the accident was as follows:

The contractor, whose duty it was to test all detonators by means of a magneto machine designed specially for such work, before the detonators were sent into the mine for blasting. He was testing one, which was in a bundle of 25, the one under test exploding, and firing the remaining 24, the cause of which was the abundant heat and force of the explosion by the one detonator, and the following should be a caution to all who are entrusted with the testing of electric detonators:—

1. When testing a detonator by means of a magneto machine, the difference of high and low tension detonators must be ascertained before put to test.

2. If the detonator is a high tension one, then do not test on the magneto.

3. In all cases a low tension tester being a high tension generator, thereby firing a high tension detonator.

4. Never test a high tension detonator on a low tension tester, else the result will be serious, due to the high tension detonator being fired.

5. Never test more than one detonator at a time.

6. Always have the detonator under test away from any one, and enclosed in an iron box.

7. A low tension detonator is fired by means of a continuous current at a potential difference of about 2 volts, the heating effects of the current causing a thin platinum wire of high resistance to get incandescent, the wire igniting a small quantity of fulminate of mercury, thereby causing the detonator to explode.

8. A high tension detonator is fired by means of an alternating current at a potential difference of about 150 volts from any alternating current source, such as a magneto, the alternating current forming a small arc which ignites the fulminate of mercury. If the contractor above mentioned had not tried to test high tension detonators on the magneto, all would have been right.

J. S. Barnes,
Electrician.

[We fail to follow the reasoning of our correspondent.—Eds. Elec. Rev.]

* By the way, a speaker, might say "naut" and yet be reported "knot."

Electric Railways.

I wish to express to you my appreciation of your "Editorial," in your issue of August 6th, 1897, reviewing my article on "Electric Railways," in the *Western Electrician*. It has been my intention to write you before, but press of business had driven the matter from my mind.

It is gratifying to note the large expansion of electrical railway enterprises abroad, and from our experience on this side of the water, I think it safe to predict success for conservatively managed enterprises in this line, not only in Europe, but throughout the world. The study of the financial side of electric railroading is a problem well worthy the engineer as well as the financier, and our experience is showing very accurately what to expect and what not to expect from this class of investments. We have learned, I think, how far to go in expensive construction and also the limit in cheap construction. The relation of capital and interest charges with maintenance cost and revenue returned, are now pretty carefully worked out and applied in considering investments.

G. W. Chance.

Philadelphia, Pa., *March 21st*, 1898.

Corporation Wiring and Fittings Departments v. Private Wiring and Fitting Firms.

Under the above heading, and with respect to the case of the Leicester Corporation *v.* Warren Hill, a report of which appears in your issue of this week, and also at the same time taking into consideration the decision arrived at by the electrical firms of Sheffield—whose early action at the critical time ought to be admired—could not the correspondence section of your paper be used to obtain the views of electrical firms in various towns.

Of course, Messrs. Warren Hill's case seems only to apply as it reads to an "over counter," or retail shop trade; but does it? It upholds and is relative to a recent article which appeared in the Review, "Municipal Wiring, &c." As mentioned in this article, the contractor was a good friend to the supply company and corporation electric department, and he could still be a greater friend if treated as such, instead of as a competitor who is doing them no good. The established contractor and the man who knows his business has quite enough to fight against in doing proper work at a fair price and competing against so-called electrical firms—who are sometimes started by persons who have no electrical knowledge worth calling, either theoretical or practical, who have no reputation, experience, conscience, or any other good qualities; their mode of business being, get the work at any price, do it in a way, turn the switch, the lamp lights, get the money and clear out. How many installations have been carried out on a system like this, without any regard as to workmanship or material, and have been a success? Surely Corporation Electric Light Departments are not formed to make profit on retailing fittings and wiring contracts; they should find looking after the supply of current a far more interesting item, and the reduction in price per unit to make it more general—the contractor will act as a canvasser without commission from them. Plenty of Corporations Electric Departments, who have the ratepayers in mind, are supplying current only, and it will be found that they are doing more to interest the cause of electric lighting and bringing it as much, if not more, into general use than the parties who must have something more to do. Perhaps they are considered to be more enterprising than those who supply current only, as it may be thought the more profit the Corporation make (and you may depend they don't work without a profit); if they do they must arrange matters extremely well to work to any extent without profit or loss; but isn't it a case of taking out of one pocket and putting in the other? Some people may think that by excluding them from wiring, &c., the electrical firms want to make a large profit and have it all to themselves, but competition in this business is too keen, and all the intended consumer has to do, is to get the work done at a proper rate to include proper workmanship and material, and carried out in a proper manner.

Now, regarding the latter part—the manner in which the work is carried out; every electric department (corporation) issues a set of rules for the benefit of the contractor, and if they only inspected the work while it is being carried out—not when it is completed as in some cases—the consumer would be under no difficulty and have no doubts regarding the work.

Trade unions and societies have and do exist, and in several cases have done more to ruin their cause and business generally. Could not a meeting be called at some central town to discuss the matter so that something could be done, and a committee formed to fully investigate a matter which is of interest to the electrical engineer and ratepayer?

E. L. Liley, Assoc. N. S. Elec. Engineers.

[Our correspondent expresses himself badly, but his meaning is fairly clear. We deal fully with the subject in our leader pages.—Eds. Elec. Rev.]

A Plea for "Six-Wheelers."

With reference to your interesting article on "Transportation," will you permit me to express a doubt as to whether the disappearance of the horse necessarily means the possibility of our streets accommodating 50 per cent. more vehicles than at present? This is often given as one of the advantages to be looked forward to in the development of motor traffic; but a little consideration will show that the process of removing the shafts from a vehicle and filling up most of the interior with propelling apparatus does not leave very much space for carrying and therefore profit-earning capacity.

Rather, perhaps, should we expect the successful motor-vehicle to be at least as long as a horse and van taken together, with six wheels instead of four—namely, central driving wheels and leading and trailing wheels acting as steerers. This arrangement, while providing ample length and accommodation, gives a *steering* length only half of the actual wheel base.

It is to be regretted, however, that so far makers of self-propelled vehicles have looked to the *cart* rather than to the *locomotive* for their inspiration.

In regard to electric vehicles, a further point suggests itself in the theoretical possibility of utilising the descent down a hill as a means of replenishing the charge in the cells, but it is unnecessary to dwell upon the great economy that may be looked for in this direction, if certain practical difficulties can be overcome.

Alfred J. Allen.

London Institution, *April 4th*, 1898.

The Institution Discussion.

On page 427, third paragraph of the right hand column of your issue of April 1st, 1898, my remarks have been summarised in such a manner that anyone reading them would think that the smashes I mentioned had occurred at Brighton. I need hardly say that this is not the case.

I mentioned Brighton as an example of a large single station, and pointed out that Mr. Wright differed from my views as to the policy of always generating a large supply from two stations. I then went on to an entirely different matter, which was the recent smashes that have occurred due to water in cylinders and which in several cases have caused breakdown of the coils of high pressure generators. This point is, of course, quite distinct from the single station question.

R. E. Crompton.

Gas Driven Plant.

I observe in your last issue a letter asking for particulars of gas driven plants. I have erected a very large number of gas engines for electric lighting, and in almost every case, certainly in 19 out of 20, I have driven the dynamo direct from the gas engine without the intervention of the counter-shaft.

Henry J. Rogers, M.I.M.E., A.I.E.E.

E

STORAGE BATTERY TRACTION IN BERLIN.

In an article by Mr. E. G. Fischinger, published in the *Elektrotechnische Zeitschrift* of March 24th, some details are given of recent experiments made with a storage battery car on the Berlin-Charlottenburg tramway system. The electrical part of the car has been carried out by the A. G. Elektricitatswerke vor. O. L. Kummer & Co.; the accumulators were supplied by the Watt Accumulator Works, and the car bodies and revolving underframes by the Dessau Gas Tramway Company. It is to be noted that the latter company also supplied the car bodies and underframes of the other storage battery cars now in operation on the same tramway. The total weight of the particular car in question, which is equipped with two shunt motors and provided with four axles, is as follows:—

	Kilogrammes.
Car and underframes	8,400
Battery of cells	6,840
Two motors and toothed gearing	1,500
Steering apparatus and other appliances ...	380
Total weight without passengers	17,120

Thus it will be seen that when fully equipped and without any live load, the weight of the car exceeds 17 tons. The battery consists of 180 cells of a capacity of from 220 to 260 ampere-hours, and with this equipment the car is capable of making 10 journeys per day, the distance covered being 96 miles. During the month of December alone the performance of the car reached 2,883 miles, the average speed being at the rate of 9·3 miles an hour, although on level sections a maximum of 14·25 miles an hour has been attained. As the pressure of the batteries ranges from 320 to 360 volts, which is dangerous for the shunt winding, the battery has been divided into two halves, and the motor armatures arranged for half the voltage. The connections are so arranged that either one or two motors, and one or both batteries, can be brought into requisition. In the tests made by the author, the measurements were taken by means of the Weston laboratory apparatus, and the results are plotted in curves which accompany the article. It appears from these that the average consumption of energy, including the mounting of gradients and passing round of curves, amounted to only 18·91 watt-hours per ton-kilometre, or, say, 30·50 watt-hours per ton-mile. The car has accommodation for 42 passengers, but during the tests the total weight of car and load reached 20½ tons, the length of track traversed being four miles.

BUSINESS NOTICES, &c

Agency.—Messrs. John Turner & Sons, of Denton, near Manchester, have appointed Messrs. Geo. Piggott & Co., of 110, Cannon Street, E.C., as sole London agents for their electrical specialities, chiefly with regard to the "Turner" dynamos and motors.

Bankruptcy Proceedings.—At a sitting of the London Bankruptcy Court, held on Tuesday last, before Mr. Registrar Linklater, Sydney George Trehearne and Arthur Haywood Crump, trading as Trehearne, Son & Crump, electrical engineers, 155, Fenchurch Street, E.C., attended for public examination. The accounts filed under the proceedings show debts £1,102 9s. 1d., and assets £449 13s. 2d. Mr. Trehearne stated that he commenced business alone in June, 1895, and was joined in May, 1897, by Mr. Crump, who brought in a cash capital of £750. The business came to a stop last December when the office furniture and effects were sold off by the Sheriff. The failure was attributed to the heavy expenses of establishing the business, losses on trading and bad debts. Mr. Trehearne was examined at some length as to the circumstances under which he had sold off a reversion to which he was entitled, and ultimately the examination of both debtors was concluded.

Birmingham Electric Supply Company v. Barnes.—This was a claim, heard at the Birmingham Police Court, for £29 10s. 9d. for electric light supplied to club premises in Barwick Street. An order for payment was made.

Bootle's Baby.—At the close of this strange winter Bootle finds itself adopting electric light. The Chloride Electrical Storage Syndicate have taken the contract for accumulators.

Dinner.—The annual dinner of the officials of the Glasgow Corporation Gas and Electricity Departments was held on 31st ult.

Disclaimer.—Mr. F. M. Rogers, of 21, Finsbury Pavement, E.C., asks us to state that he is not the Mr. Rogers mentioned in the case of Crompton *v.* Liardet, reported in our issue of March 25th, p. 396.

Dissolution of Partnership.—In regard to last week's notice of Messrs. Harrison, Coles & Co.'s dissolution of partnership, Mr. Pringle asks us to state that though the partnership has been dissolved he is still carrying on the business as heretofore.

Fippard & Cooper.—This firm, of Albert Road, Bournemouth, has at present in hand electric light installations for St. John's Church, Bournemouth, Congregational Church, Westbourne, and Boswell's Circus.

Hodges and Todd v. Watson and Another.—This action was brought before Mr. Justice Wright, without a jury, in the Queen's Bench Court last week, by Messrs. Hodges and Todd, of Hampstead Road, London, to recover damages for breach of contract; the defendants, Mr. Arnold T. Watson, of Sheffield, and Mr. Robert Hodgson, of Hull, denied the breach. Mr. T. W. Chitty and Mr. J. H. Gray appeared for the plaintiffs; Mr. R. M. Bray, Q.C., and Mr. Marshall Hall for the defendants. Mr. Bray, in opening the case, said that the defendants agreed in January, 1897, to supply to the plaintiffs a Priestman oil engine of 24-brake H.P., suitable for working an electrical installation at the residence of a gentleman called Combe. The engine supplied was not sufficiently powerful, and worked in a noisy manner. Evidence was called in support; with reference to the noise one witness stated that the engine was generally known as "Mr. Combe's artillery," and another said that having lost his way while riding his bicycle he was guided back by the noise of the engine. Mr. Priestman was called for the defence and stated that his engine had been on the market for about 12 years. The engine in question, when tested, showed a power of 24·6 H.P. He thought it suitable for the purpose required if properly worked. Further evidence having been called for the defendants, Mr. Justice Wright delivered his judgment. According to the *Times* report, he said that the difficulties had arisen to a great extent from a miscalculation of the margin of power in these engines. The margin of power appeared to be small. He was satisfied that as this engine was adjusted in February, 1897, it was capable of working up to 24-brake H.P. according to the contract, but he was also satisfied that as it was fixed in July it would not work anywhere near up to 24-brake H.P. The main contention of the plaintiffs failed because it was an engine of 24-brake H.P., but they had a cause of action because the defendants had contracted to fix and start it as a 24-brake H.P. engine, but did not do so. It was an extremely difficult matter to assess the damages, but the defendants had minimised the loss by now agreeing to take back the engine and return the money, though they were not obliged to do so. In addition, there would be judgment for the plaintiffs for £50, but without costs, as the plaintiffs had failed in their main contention.

Lighthouse Illuminants.—In reply to a question put by Mr. H. Plunkett in the House of Commons last week, Mr. C. T. Ritchie said that the Elder Brethren of the Trinity House did not consider that the great additional expenditure necessary for installing and maintaining two separate electric light stations would be justified in the case of Lundy Island. The question whether electricity, gas or oil are to be adopted as illuminants in the future must depend to a great extent on the circumstances of the particular lighthouse.

Liquidation Notices.—A general meeting of Latimer Clark, Muirhead & Co., Limited, is to be held at the offices of Messrs. Trinder, Capron & Co., 47, Cornhill, E.C., on Monday, May 2nd, at 3 o'clock for the purpose of hearing an account of the winding up proceedings from the liquidator, Mr. J. Worley.

Lists.—Mr. William Patterson, of Walker Gate, has issued a list of copper wire gauze dynamo brushes.

The United Ordnance and Engineering Company, Limited (Messrs. Easton, Anderson and Goolden, Limited, of Erith), have issued a pamphlet well illustrated both by means of photographic and other views, in which they describe their multipolar continuous current dynamos and motors. In tabulated form there are given particulars, prices, weights and overall dimensions. Views are shown of the winding, erecting and brass finishing shops, and the test-bed at Erith.

Parabolic Reflectors.—A sole license has been granted to Messrs. Chance Bros. & Co., Limited, of Smethwick, for the manufacture of parabolic reflectors for search lights by the Cowper-Coles electrolytic process.

Partnership.—Mr. L. Alwyn, of Cowcross Street, E.C., informs us that he has taken the Hon. Rupert Craven into partnership, and the style of the firm will henceforth be "Alwyn & Craven," of the above address. All outstanding liabilities to date will be discharged by Mr. Alwyn.

Portable Galvanometer of the d'Arsonval Type.—The Weston Electrical Instrument Company, of America, have recently got out a new form of testing galvanometer, made up in exactly the same sort of form as their well-known ammeters and voltmeters. In this instrument the moving coil is exceptionally light, and is wound with about 300 ohms resistance. A light pointer is provided, and the sensibility of the instrument is such that one volt applied to the terminals through an external resistance of 250,000 ohms gives a deflection on the scale of about 1 millimetre. The instrument is in a very compact case, and is very handy for portable work in resistance, measurements and potentiometer work of all sorts. Messrs. Elliott Brothers, acting as agents for the Weston Company, are keeping these instruments in stock.

"Relugite" Resistances.—From the Electric Insulation Syndicate, Limited, of East Moors, Cardiff, we have received a catalogue of the "Relugite" resistances and other apparatus manufactured by them. "Relugite" is a new elastic and compressible resistance material, the resistance of which can be raised by pressure, and by means of this and of improvements in the means of applying it, a novel and useful series of resistance appliances is made. The following are among the specialities which are described and priced:—Dynamo and motor shunt resistances, arc lamp resistances, regulating ditto, special resistances in standard frames, motor starting resistances, "Standard" "Relugite" electric stoves or regulators, and lamp switches.

South African Electrical News.—We glean the following items of interest from the April issue of the *British and South African Export Gazette*:—The electrical installation at the Woodbine gold mine, De Kaap, comprises three 50-B.H.P. 200-volt three-phase motors, two to serve the mill and one the air compressor; two oil-transformer-type transformers, of 100 kw. and 50 kw. respectively, wound for a high tension of 10,000 volts and a low tension of 200 volts, and were supplied through Messrs. Reunert & Lens. Orders for 500 lamps, with their fittings and accessories, for the electric light service of the post and telegraph office now in course of erection at Johannesburg, are about to be placed by the Transvaal authorities. The electric lighting and tram plant which the East London (Cape Colony) Town Council are about laying down is estimated to cost £25,000. A scheme for electric lighting the public buildings, shops, and private houses of Kimberley is proposed. Among the latest towns in the Cape Colony meditating the introduction of electric lighting is Queenstown. Proposals for supplying the light have already been submitted to the Council by Mr. E. T. Monteath, E.E., which have been handed to the Lighting Committee for consideration and report. Woodstock, a municipality situated 1½ miles from Capetown, is considering the advisability of a similar installation. Repeated extensions mark the tramway system of Capetown, the latest being to Plumstead, a suburb situated about nine miles from the metropolis, and the project is even being entertained of forming a link with Muizenberg, a favourite seaside resort 15 miles from Capetown. The track connecting Wynberg with Capetown is expected to be shortly ready for opening. This will add another eight miles to the existing electric network, which, with the several extensions referred to, will make a total of 33 miles.

Telephone Contract.—Mr. James Pollock, of Glasgow, has received an order for the erection of a complete telephone plant throughout the Western Infirmary, Glasgow. We understand that Mr. Pollock has completed a number of telephone installations of this kind, besides having erected upwards of 600 private telephone lines on rental throughout the city.

ELECTRIC LIGHTING NOTES.

Bath.—Mr. R. Hammond, in his last monthly report to the Electric Light Committee, reported that 17 arc lamps had been erected in the city, and the total number cast was 53. He also stated that with respect to the switchboard extensions, specifications were sent out to different firms, and recommended the acceptance of Messrs. Madder's tender at £253.

Brewery Lighting.—Messrs. O. Edwards & Sons, brewers, have introduced the electric light into their brewery and other premises at Tenterden.

Brighton.—At the Council meeting on Thursday last week the Lighting Committee submitted a report, which contained an announcement that Mr. Arthur Wright, the electrical engineer, had accepted the post of consulting electrical manager of the British Thomson-Houston Company, Limited, the terms of his arrangement enabling him to give at least half his time to the Corporation. The committee submitted accounts of the past year's trading. The gross revenue was £32,722 17s. 10d., of which £18,512 4s. 6d. were expended on maintenance, and £14,210 13s. 4d. carried forward. Leaving £110 13s. 4d. of this as provision for bad debts, and adding £5,000, balance from 1896, the Corporation had in hand £19,100, of which £2,000 were applied in aid of the district rate, £3,000 transferred to reserve fund, £5,688 5s. 6d. paid as interest, £5,547 9s. 1d. to the sinking fund, and £2,864 5s. 5d. carried forward to 1898 account. Private consumers purchased 1,505,867 units last year, and the public lamps consumed 486,634 units; 116,693 units were used in the works, and 335,977 units represented the extra quantity generated, but not accounted. An elaborate report, recommending a reduction in the charge for electricity after the first hour's average daily use from 1½d. to 1d. per unit, had been submitted to the committee by Mr. Wright, who concluded as follows:—"I trust that the policy inaugurated by the Lighting Committee of the Brighton Corporation in vigorously encouraging the use of electricity among the vast body of small ratepayers, who, either in their business or private residences, are in the habit of using artificial light for many hours per day throughout the year will be continued, and thus keep Brighton in the enviable position which it now holds, of being the first to enable the smaller ratepayers and householders to benefit by the many advantages of electricity." The committee resolved: "That from and after June 30th next, the charge for electricity after the first hour's consumption be reduced from 1½d. to 1d. per unit."

Bristol.—The report of the electricity department of the Corporation for the year ending March 25th, 1898, shows a very great advance upon the working of former years. At the date of the last return, *i.e.*, March, 1897, the department had connected to their mains 614 customers with 38,502 lamps. At the present date there are connected 814 customers with 49,917 lamps, showing an increase of 200 customers and over 10,000 lamps. The extension of the public lighting has not yet been carried out, but is in progress, and before the summer is over it is expected that the number of public arc lamps will be increased three fold. Extensions of the mains for private lighting have been, or will be made within the next two months, in various roads. The number of sub-stations has been increased from 31 to 39. The extensions at the generating station in Temple Back have been almost completed. Of the buildings, the new chimney and the coal bunkers are practically the only portions incomplete. Five new boilers have been put in, together with a new elevator, conveyor, and mechanical stokers and electric motors for driving these, and the sundry pumps are now being placed in position. One new steam alternator has been fixed and brought into use, and two others will be put in during the summer (these three machines alone are capable of keeping over 40,000 lamps alight at one moment). In addition to the alternators other steam dynamos have been and are being put in for public lighting and the supply of power. Various important buildings have been fitted with electric light during the year. The following table shows at a glance the financial progress of the electricity department. For the purpose of making the annual accounts agree as to date with the other accounts of the Corporation, these are now made up to March 25th, whereas formerly the financial year ended at December 31st, as required by the Board of Trade; thus it will be noticed in the following table that between the third and fourth year there are included in the figures the working for a period of three months only. It is interesting to note the relation in the profits arising from such three months, they being during the winter season, as compared with the whole year's working. The net profits during those three months far exceeded the whole of the profits for the previous year, and were only a few hundred pounds less than the profits for the succeeding year. The trading profits for the past year exceed 8 per cent. of the capital expended at the end of the term, although a considerable amount of this capital has been expended on buildings and plant which have not yet come into operation, and thus have not tended to swell the revenue.

City Electrical Engineer's Department Progress Table.

Year of working.	Customers connected.	Lamps connected.	Net profits.	Trading profits. Amount.	% of capital expended per annum.
			£	£	
1st ending Dec., '94	240	14,530	Loss	456	½ %
2nd " '95	439	24,046	Loss.	4,020	4 %
3rd " '96	593	30,299	2,487	7,590	7 %
*3 months Mar., '97	617	38,826	2,738	3,722	13 %
4th ending Mar., '98	749	49,719	3,290	11,307	8 %

* The results given in this line are for three months only, and the per cent. capital given as 13 per cent. is unusually high, as it is for a winter quarter only, and represents the rate per annum.

The Bristol Sanitary Authority has refused permission to Messrs. Spillers & Baker *re* laying wires under the roadway on Redcliff Backs for electrically lighting their premises.

Dublin.—The chairman of the Alliance and Dublin Consumers' Gas Company, addressing the shareholders last week, said that whatever apparent loss might have taken place by the use of the electric light, it was more than made up by the extended use of gas for cooking, heating, and gas engines. They would be interested to hear that large establishments were beginning to discover that to produce electric light at a very low cost they must have their own installations, and hence within the last 12 months a number of large gas engines had been erected in the city for electric lighting.

Durham.—The Cathedral authorities want to light up the Cathedral with electricity, and they have approached the Town Council to see if that body would permit the local gas company to apply to the Local Government Board for an electric lighting provisional order. The Council is considering the matter.

Eccles.—The laying of the electric light cables is to commence early this month. Rapid progress is being made with the station plant. The Electric Light Committee has fixed the rental for 5-ampere meters at 2s. 6d. per quarter, with a scale up to 100 amperes at 6s. per quarter. The electrical engineer says that the cable included in the private lighting estimate will be totally inadequate for the demand. It will supply 2,400 lights, but he suggests one that will be equal to 4,000 lights from Cawdor Street generating station to the Polygon. This proposal the committee has adopted at an increased cost of £119.

Edinburgh.—The Electric Lighting Committee has resolved to recommend, on a report from Prof. Kennedy, that the charges for current be reduced in June to 3½d. per unit with the ordinary discount; for each public lamp £14 per annum, and for motive power 1½d. per unit. It is suggested that the salary of the resident electrical engineer should be increased from £500 to £600 per annum.

Festiniog.—A proposal to light the district electrically was recently before the Gas and Water Committee from an electrical engineering firm. The Council has resolved to prepare an estimate of the cost and to inquire the experience of other towns.

Folkestone.—It is stated that the capital of the Folkestone Electricity Supply Company has been subscribed twice over. The amount offered to the public was £27,500, and application was received for shares to the amount of £75,000.

Hampstead.—Sixteen tenders were sent in for additional electric lighting plant at the central station, and they have been referred to the Lighting Committee. Messrs. Massey & Allpress are preparing specifications for the Guardians for electrically lighting the workhouse.

Kilmallock, Co. Limerick.—Mr. J. J. O'Sullivan, J.P., has made arrangements with the Markets Committee for the public lighting of this town, and is also putting down a plant for private consumers. The mains extend in four circuits of about quarter mile each, and the current will be delivered to the customers at 200 volts. Hitherto the town has depended upon oil as its illuminant, but nearly all the residents are now wired for electric lighting, the greater number not having more than three lamps and at a fixed contract price per annum for current, which has given satisfaction to the consumer and should prove remunerative to Mr. O'Sullivan. We wish the enterprise every success, as the lighting of small towns by electricity is opening a large field for the electrical industry. It has certainly given the lead to the neighbouring city of Limerick, whose provisional order dates several years back. The engine is being supplied by Messrs. J. and R. Lees, of Glasgow, and the dynamo, switchboard, wires, and general fittings are by the Edison & Swan United Electric Light Company, Limited.

Leeds.—On 31st ult. a Local Government Board inquiry was held at the Town Hall regarding the City Council's application for a provisional order (1) to empower the Corporation to create irredeemable stock bearing a dividend at a rate not exceeding 5 per cent. per annum, in order to issue or transfer the same to the undertakers, as provided in Clause 59 of the Leeds Electric Supply Order, 1891; and (2) to confer on the Corporation such borrowing powers, and powers to create and issue redeemable stock, as may be necessary in connection with the purchase of the undertaking of the Yorkshire House-to-House Electricity Company, Limited. The position of affairs was explained in detail by the Town Clerk.

The Great Northern Railway Company has asked the Corporation to extend the electric light farther along Wellington Street.

Lincoln.—At the Council meeting on Tuesday the Electricity Works Committee recommended that:—(1) The price of supply be 6d. per unit for first hour's average maximum demand, and 2½d. per unit afterwards. (2) That a contract be entered into with the National Electric Free Wiring Company to "free wire" any consumers who wish to take advantage of this method of providing themselves with wires and fittings. We understand that the works are in a very forward state, and supply will be given on October 1st next.

Peterborough.—A number of councillors are enraged at the stand which is being maintained by the Local Government Board in regard to the application for an electric lighting loan. It seems that the margin of borrowing power now remaining to the Council is not more than £26,160, and as £15,000 or £16,000 is to be spent for water supply, there would not then be sufficient to enable the Council to meet the city's requirements in this respect, if £15,000 is allowed for electric lighting. The Board, therefore, declines to comply with the application. The Town Council has had a very long discussion, and decided to send a deputation to wait upon the Board.

Ryde (Isle of Wight).—An inquiry was held last week into the application of the Ryde Electric Light and Power Company, Limited, for a provisional order. The Corporation opposed the application.

Sheffield.—A special meeting of the City Council has been fixed for Wednesday, April 13th, regarding the proposed application for an Act "To confirm an agreement for the purchase of the undertaking of the Sheffield Electric Light and Power Company, Limited, by the Corporation of Sheffield, and to confer borrowing powers and other powers on the said Corporation."

Shipley.—The Special Committee cannot recommend the purchase of the Baildon Bridge Mills for electricity works site, as the price is far too high.

Southend.—A special meeting of the Ratepayers' Association was held some days ago, when Mr. Kershaw, chairman of the Shoreditch Electric Lighting Committee, gave an address on the merits of electric lighting. He referred to tramways and dust destructors.

Spain.—A central station for the supply of electrical energy for lighting and power purposes to several small towns in the neighbourhood has lately been completed and put in operation at Tarancon. The water-power of the River Tajo is utilised, the plant comprising three 120-H.P. turbines, and a large 250-kilowatt multiphase alternator, the latter having been supplied by Messrs. Brown, Boveri & Co., of Baden, Switzerland.

Swansea.—A special meeting of the Corporation is to be held to consider Mr. Manville's report on electric lighting.

Weston-super-Mare.—Negotiations are in progress with the Great Western Railway for land for electricity works site.

Willenhall.—The District Council has affixed its seal to the agreement of the Midland Electric Corporation for Power Distribution, Limited.

Withington and Moss Side.—The Manchester Electricity Committee held a special meeting last week to consider a proposed extension of the city electric lighting system to Withington and Moss Side, under agreements with the Withington and Moss Side authorities. The estimated cost of extending the system to these suburbs, and of completing certain works, is £138,000. It was decided to apply for sanction to borrow £150,000.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Belfast.—It is stated in a Dublin paper that a special committee, recently appointed by the Belfast Corporation, is at present making active inquiries as to the cheapest and most efficient means of providing electric tram traction in those districts through which the horse car service of the Belfast Street Tramways does not at present pass.

The Secretary of the Tramway Company wrote to the Electric Committee on March 7th to the effect that the directors are not prepared to establish electric traction upon the Belfast tramways for the short remainder of their term, nor do they believe that any possible terms can now be suggested which would justify them in so doing. The Corporation had a long discussion on the matter last week.

Bristol.—The report of the Bristol Sanitary Committee upon electric traction and their negotiations with the Tramway Company (of which the pith was given last week in the Electrical Review) was discussed for two hours by the Town Council, and the members appeared to agree with a concluding remark that the debate had "cleared the air." The motion of the Chairman of the Sanitary Committee was, in effect, to oppose the Tramway Company's Bills, but the scope of the discussion was largely influenced by an amendment moved by Alderman Inskip in the following terms: "That this Council is of opinion that, subject to the settlement of all proper clauses for the protection of the public interests, it is desirable to conclude arrangements with the company for the withdrawal of the Corporation's petition against the Bristol Tramways (Electrical Power, &c.) Bill, upon the condition that the purchase periods of all the existing lines, together with all new lines to be hereafter constructed within the City and County of Bristol, shall fall in at the expiration of 18 years from the passing of the Bill; and the Sanitary Committee are hereby instructed accordingly." The purport of that amendment seemed to meet with almost general approval, but the wisdom of fixing a term in the resolution was criticised by many as fettering the Committee needlessly. The horse cars forming the main part of the Bristol Tramways are purchasable in about 14 years, or lines at longer periods, so that Mr. Inskip stated that the average period including the present extensions was 17¾ years. He intimated he was in a position to say the tramway company would accept 18 years. Mr. George Pearson, Chairman of the Electrical Committee, criticised the tramway company's action in offering to Alderman Inskip terms not offered to the Committee which had been negotiating, and pointed out there were one or two other matters for consideration. The company refused to think of anything but the overhead system, although an alternative underground system in a few streets where the overhead wires would be objectionable, could be easily worked in conjunction with the trolley system generally applied. His view was that the company should be bought out at once, and he believed it could be done with financial success by the city. Eventually Alderman Inskip withdrew his amendment, and accepted another, which asked the Committee to continue negotiations with a view to settle a fixed period for purchase of all undertakings, and to make terms and arrangements with regard to overhead wires and other matters, and report at the earliest opportunity. This was agreed to.

Coatbridge and Airdrie.—The Light Railway Commissioners held an inquiry at Coatbridge on 29th ult., regarding this light electric railway scheme promoted by the British Electric Traction Company. Mr. Morse explained the proposal, which was to run a railway from Blair Street, in Coatbridge, to Forsyth Street, Airdrie, a distance of three miles. The gauge would be 3 feet 6 inches. The Councils of Airdrie and Coatbridge wished this extension to be the same as the tramways of Glasgow. This the Traction Company is prepared to accede if the Commissioners think it desirable. The chief objection of Airdrie and Coatbridge Town Councils is the using of the proposed railway for the conveyance of minerals without their consent. The Council of Coatbridge also desire that the railway be extended westward to Woodside Street, and a branch line from the Cross to Sunnyside Station. While the Airdrie Council request it extended eastward to Carlisle Road, the Traction Company was also prepared to allow the Corporation to purchase the railway at the end of 21 years, instead of 35 years, as mentioned in the order. The N. B. Railway and Caledonian Railway opposed the scheme.

Crowborough.—A meeting was held on Wednesday evening at Nutley in support of the proposal to construct a light railway from Nutley through Crowborough to Groombridge. It was considered desirable to have the railway facilities improved, and a committee was appointed.

Derby.—Messrs. Kincaid, Waller & Manville are proceeding with the valuation of the tramways for the Corporation.

Dublin.—The Court of Referees of the House of Commons had before it last Thursday applications from the Gas Company and the Dublin and Wexford Railway Company for *locus standi* as petitioners against the Dublin Southern District Tramways Company Bill, under which power to run at increased speed is sought. The Gas Company was disallowed, but the Railway Company has been allowed a *locus* on the ground that the proposed change would create a new form of opposition.

Electric Tramways v. Kew Observatory.—The instruments used at Greenwich to register the variations in the earth's magnetism, and so on, are so delicate that they are appreciably affected by the establishment of the electric railway to Stockwell. Experiments made elsewhere show that the sending of a strong electric current through a district can affect these instruments at 12 miles distance. On these grounds, says the *Financial News*, the London United Tramway Company's Bill is going to be opposed on behalf of the Royal Society's Observatory at Kew. The scheme of the company embodies eight lines between Hammersmith, Ealing, and Hounslow, with electric traction substituted for horse-power. The Richmond Corporation will also oppose, being desirous of working the Richmond-Kew line for its own benefit.

Hanover.—In 1897, according to the annual report of the Hanover Tramway Company, electric traction has been introduced on all the tramways within the municipal boundry of Hanover. The conversion has been carried out one year sooner than time limit fixed by the authorities. Along with the report a map is published showing in different colours the sections of the lines worked by accumulators, and the sections worked by overhead conductors; and also the positions of the power stations. The cost of maintenance and renewal of the accumulators amounts to 46·18 marks per car per month; 1·22 pfennig per kilometre of the mixed system; 2·06 pfennige per kilometre of the accumulator system. Although it was not possible in 1897 to finish all the projected lines, or to start the working of those which were finished soon enough to show a financial success, nevertheless the profits have increased by about £13,800. The following lines are in course of construction:—1. Laatsen to Hildesheim. 2. Rethen to Pattensen. 3. Sieben Trappen to Gehrden. 4. Various small sections. The lines one to three are to carry goods as well as passengers. Some of these lines, for example, that to Hildesheim, run a distance of 20 miles from Hanover. Both power and light are supplied to the neighbouring parishes from the power stations. The expenses amounted to 63·8 per cent. of the total income, as compared with 68·2 per cent. last year. The power stations are at Glocksee, Vahrenwald, Kirchrode, Buchholz, Rethen, and Schude. At Glocksee there are four tubular boilers, each having a surface of 180 m^2, and two combined Cornish boilers, each with a heating surface of 200 m^2. Recently erected, there is one tubular boiler with a heating surface of 272 m^2. As to steam engines, there are four horizontal engines, each of 200—250 H.P., and one vertical engine of 350—460 H.P. The direct coupled dynamos have a normal output of 760 kilowatts, and a maximum of 960 kw. The report also specifies the plant in the other power stations. Buffer batteries are used to equalise the output from the dynamos. The central station at Glocksee is to be connected with the outer stations, and the depôts by telephone. The rolling stock at the end of the year consisted of 23 motor cars of the old type for overhead lines; nine motor cars of the old type for both overhead and accumulator working; 110 motor cars of the new type (one motor) for combined accumulator and overhead working; 17 motor cars, new type (with two motors), accumulator and overhead working; one snow plough (one motor) for overhead lines; one snow plough (with two motors) for overhead lines, used in summer as a water cart; one water cart for overhead lines. The number of horses at the beginning of 1897 was 253; this number has now been reduced to 50. A dividend of 5 per cent. has been paid, after making ample allowance for depreciation, &c.

Kidderminster and Stourport.—According to the *Birmingham Post* for April 1st, this tramway is now fast approaching completion, and we understand that in about a fortnight's time the contractors will have finished the works in hand. The only remaining piece of the permanent way to be done is that which has to be constructed over the level railway crossing at Stourport. The Great Western Railway have the construction of this to do, and it is to receive early attention. All the poles used for the purpose of suspending the trolley wire along the route are fixed, and the greater part of the trolley wire has already been attached. The whole of the underground cables have been laid. Some important road and bridge widenings were included in the scheme, and these have all been completed, and long lines of iron fencing have been erected where the road to Stourport has been widened.

London.—The London United Tramways Company's Bill for providing electric trams for West London passed the Standing Orders last week, and has been introduced into Parliament. The company proposes to run electric cars from the Broadway, Hammersmith, direct to Hounslow, passing through Chiswick, Turnham Green, Brentford, and Isleworth, whilst another and almost parallel line will run from Uxbridge Road, Shepherd's Bush, to Hanwell, through Acton and Ealing. The company promises to permit the local authorities of the districts through which the cars run, to use the standards for electric lighting, so that the whole of the West London suburbs may be lighted with electricity.

Northampton.—The Northampton Street Tramways Company is desirous of reorganising and improving the tramway service of Nottingham, but, as the Corporation has power to purchase the lines in 1901, the company has written suggesting that the Corporation should at once purchase, on terms to be arranged, the whole of the tramways, or should agree not to exercise the option of purchase until 1919, or thereabouts. Early consideration of the matter is requested.

Norwich.—It is expected that the construction of the electric tramway lines will be commenced shortly after Easter; 500 tons of rails from Belgian contractors are on the way. Continuous rails, with welded joints, are to be used. The trolley poles will come from America. The routes to be first taken in hand will be the Thorpe Road, Newmarket Road and Dereham Road.

Nottingham.—There has been a good deal of local discussion regarding the tramway question, and the special committee which was appointed a few months ago by the City Council to inquire into the matter has issued a lengthy report, the recommendations made therein being:—1. That the permanent way of the whole of existing system shall be reconstructed. 2. That certain important extensions to this system, given in full detail later in this report and shown on the sketch plan, shall be carried out as soon as Parliamentary powers can be obtained. 3. To equip the whole of the system on the principle of electric overhead traction. The report discusses overhead electric traction *versus* cable traction, the committee having inspected lines equipped by both methods. The merits of the electrical systems, *i.e.*, the conduit, accumulator, and trolley, are considered. The total estimated cost of the reconstruction of the existing tramways and the proposed extensions, including the overhead electrical equipment, cars, and car sheds, power station and plant, &c., is £425,000. The Council is advised to obtain the necessary Parliamentary powers, and to empower the Finance Committee to raise the capital required.

Paris.—The Compagnie Générale des Omnibus has applied for official permission to convert three more of its horse tramways in Paris into electric lines.

Whitley.—On 31st ult. a public inquiry was held at North Shields by the Light Railway Commissioners regarding the proposed extension of the tramway system, and the introduction of the overhead trolley by the British Electric Traction Company. Mr. Sydney Morse explained the scheme. He said the new line would be partly in the borough of Tynemouth, and partly in the Whitley and Monkseaton Urban District. The gauge of the proposed line would be 3 feet, and the engineer's estimate for the undertaking was £11,356. There were to be two new lines or extensions, the first being within the borough of Tynemouth and 2 furlongs in length. It would run from the present terminus in Saville Street, West, down the Borough Road to the penny ferry leading on the New Quay. The second one would be 1 mile 5½ furlongs, and would run through Cullercoats and end at the Ship Inn, Whitley. Of the latter distances 1 mile 1 furlong were in the borough of Tynemouth, and the rest in the Urban district of Whitley. There would be no difficulty in construction, the only heavy gradient being 1 in 11, and it was very short. It was said that some millions of passengers used the ferries in the year, and, therefore, with this very important traffic it was essential that the facilities suggested should be given. At present the tramways were run by a slow and unsatisfactory method, and the local authorities had long considered that there should be some change for the better. Mr. Morse then referred to the past negotiations which had failed between the Corporation and the late North Shields Tramway Company, and added that although there had been a great deal of correspondence on the subject of improving the trams there had been no practical results. The Corporation had an order for supplying electrical energy to the borough, and in February, 1897, they passed a resolution in favour of the trams being driven by electricity. Excepting three clauses in the order which the company sought to obtain under the Light Railways Act, everything had been agreed upon, but in these clauses the local authorities sought absolute veto upon matters vital to the undertaking. There were three objections by the Corporation. The first referred to the future purchase of the undertaking by the Corporation, the second to the paving and subsequent repairing of the roads by the company, and, thirdly, that in the event of a dispute arising the questions at issue should be referred to the Board of Trade. The latter clause was important to the company, as they considered it only reasonable and desirable that an independent authority should be called in to bring about a settlement. The company could not accept terms which might prove disastrous to them, and if some amicable arrangement could not be come to, the company would seek to carry out their business elsewhere. Mr. Garcke gave evidence in support of the scheme.

TELEGRAPH AND TELEPHONE NOTES.

Fire at Zurich Telephone Station.—A Reuter despatch says that:—"In consequence of a telephone wire falling upon the overhead wires of the electric street tramways at Zurich, the central station of the telephonic service, which has 5,000 subscribers, caught fire and was completely destroyed. The damage to the building is estimated at over £40,000, while the losses caused indirectly amount to at least the same figure."

The Pacific Cable.—A Reuter despatch from Hobart says that at Monday's sitting the Inter-Colonial Conference agreed that in the absence of a satisfactory proposal from the Eastern Extension Telegraph Company, no fresh arrangement could be made with the company. A motion was passed in favour of the speedy construction of a Pacific cable.

The Telegraph System.—Few people, says the *Daily Chronicle*, have any adequate idea how large the annual balance on the wrong side really is. The capital amount of Consols created in respect of money raised for the purchase of telegraphs, &c., stands at, net, £10,868,664, on which interest at 2¾ per cent. amounts to £298,888. The expenditure on salaries, rent, maintenance, buildings, stationery, rates, &c., amounted to £3,111,810. The gross receipts were £3,287,611, and the net receipts, deducting the amount paid to cable companies and telegram moneys refunded, £2,922,449, but to this is added £44,905, being the value of services performed for other Government departments without remuneration, total £2,967,354. There has been a deficiency in every year since the purchase of the telegraphs by the State, and the aggregate from the beginning of 1871 to March 31st, 1897, amounted to a total deficiency of £6,629,890.

The Telephone Service.—In the House of Commons, sitting in committee, on Monday last, a resolution was moved authorising the payment out of the Consolidated Fund of a grant of £1,000,000 for the telegraphs. Dr. Clark: Has this anything to do with the telephones?—Mr. Hanbury: A sum of money has already been paid for the trunk lines of the telephones, and this is to complete it.—Mr. Lough objected to large sums of money being voted in this way.

CONTRACTS OPEN AND CLOSED.

OPEN.

Accrington. — April 19th. The Corporation wants tenders for the supply and erection of three sets of steam dynamos, each set consisting of a triple expansion condensing steam engine of the inverted vertical type, 90 I.H.P., and of a shunt wound dynamo. Also a feed water heater, storage battery having a capacity of 750 ampere-hours, switchboard instruments, apparatus cables, wires, street boxes, connections, &c. For further particulars see our "Official Notices" April 1st. Consulting engineer, Mr. J. N. Shoolbred, 47, Victoria Street, S.W.

Belfast.—April 18th. The Harbour Commissioners are inviting tenders for the supply and erection in the electric light station, Abercorn Basin, Belfast, of three compound, two-crank, self-lubricating, single-valve quick revolution vertical engines, each capable of developing 70 H.P., with a steam pressure of 130 lbs. per square inch. Also for three belt-driven, continuous current, series wound dynamos, capable of giving 15 amperes, 2,850 volts, at a speed not exceeding 800 revolutions per minute for 18 hours continuous running, without undue heating. Specification and further particulars from the harbour engineer, Mr. G. F. L. Giles. See our "Official Notices" this week for particulars of these two contracts.

Derby.—April 12th. The Corporation wants tenders for the electric wiring of its Ford Street yard and premises. See our "Official Notices" March 18th.

Derby.—April 11th. The School Board want tenders for the electric wiring of the Traffic Street Board School, Derby. Particulars from Mr. J. E. Stewart, Corporation electrical engineer. See our "Official Notices" March 25th.

Edinburgh.—April 23rd. The Midlothian and Peebles Lunacy Board is inviting tenders for the installation of electric light in the Asylum at Rosslynlee, near Edinburgh, including (1) generating plant, accumulators, switchboard, &c.; (2) wiring, fittings, &c. Particulars may be obtained on application to Prof. Bailey, Heriot-Watt College, Chambers Street, Edinburgh.

Shoreditch.—April 12th. The Vestry wants tenders for the supply and erection of arc lamps and accessories, also for electric light cable. Electrical engineer, Mr. C. N. Russell. See our "Official Notices" March 25th.

Switzerland.—April 15th. The Works Department of the Municipal Council of Berne is inviting tenders until the 15th inst. for the supply of between 60,000 and 70,000 metres of low tension cable (for 250 volts), and from 27,000 to 35,000 metres of high tension cable (for 3,000 volts) ranging from 15 to 150 sq. metres in section, as also the necessary junction pieces, distributing boxes, &c., for the new municipal alternating current system. Tenders to be sent to La Direction des Travaux de la Ville, Berne, Switzerland, from whom particulars may be obtained.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

Hammersmith.—The Vestry has accepted the tender of Mr. T. W. Thomas (£3,504) for the extension of the electricity works. Messrs. W. T. Glover & Co.'s tender for switches for 50 new arc lamps at £5 each has been accepted.

Middlesex.—The Asylum Committee of the Middlesex County Council has accepted the tender of Messrs. Veritys, Limited, for lighting the recreation hall and the stage therein by electricity, at the sum of £289.

NOTES.

Mr. Crompton's Smashes.—It is thought that our report last week of Mr. Crompton's remarks on the subject of Mr. Hammond's Institution paper may suggest that when the speaker was referring to a good many smashes he had Brighton in his mind. This matter is made clear by Mr. Crompton's letter in our "Correspondence" columns, and since that part of this issue went to press we have received a letter from Mr. Arthur Wright on the subject. This will appear next week.

Magnetism and Diamagnetism.—In the fifth and last lecture of his course on "Recent Researches in Magnetism and Diamagnetism," delivered at the Royal Institution on Thursday last week, Prof. J. A. Fleming dealt with the subject of magnetic theories. After briefly pointing out the nature of older views on the causes of magnetic action, he said, according to the *Times* report, that all modern physical theories were based on the denial of action at a distance, and on the conviction that in the ultimate analysis all invisible as well as visible physical actions could be reduced to simple mechanics. The origin and explanation of physical effects were sought for in the interactions of matter, ether, and energy, governed by the fundamental principles of dynamics. From this point of view electric and magnetic phenomena were regarded as events happening in the ether, modified by the presence of matter. The nature of these events could only be determined in terms of some hypothesis as to the structure of the ether, and the suppositions made must be justified by their power to predict new facts. The lecturer passed on to discuss the probable molecular structure of the ferro-magnetic metals, iron, nickel, and cobalt. After some experiments indicating that each small particle of magnetised iron was itself a magnet, a model magnet made up of a large number of small compass needles pivoted on a board at equal distances was shown to exhibit all the characteristics of a piece of iron subjected to magnetisation, and it was pointed out that these small magnets produced by their mutual action (as first shown by Ewing) all the phenomena of hysteresis, retentivity, and coercivity. Referring next to the probable ultimate causes of the magnetic properties of the iron molecule, Prof. Fleming discussed various hypotheses and gave arguments for and against the well-known theories of Ampère and Weber. Experiments and illustrations were brought forward in support of the view advocated by the lecturer that the causes of the magnetic properties of the iron molecule were most probably to be looked for in the magnetic field produced by the rotation of a molecule built up symmetrically of atoms carrying electric charges. This hypothesis led to a simple explanation of the disappearance of ferro-magnetic susceptibility beyond a certain critical temperature, characteristic of iron, nickel, and cobalt. All recent work strongly confirmed Maxwell's electro-magnetic theory of light, according to which light consisted of a rapid alternation of electric displacements and magnetic flux taking place in the ether at any point. The energy of sunlight (equalling 10,000 foot-pounds per cubic mile) was half magnetic and half electric, the *maximum* value of the electric force in a ray of sunlight being equal to 200 volts per foot, and of the magnetic to about one-tenth of the earth's horizontal magnetic force. No proper account, however, the lecturer observed, could be given of the nature of electricity or magnetism until it was known what was the nature of the physical change in the ether that produced what was called an electric displacement or a magnetic flux.

Acknowledgment.—The three notes on pp. 448, 449, and 450 of our last issue, headed "In Honour of M. Gramme," "Large Continuous Current Dynamos," and "French Import Duties on Lead and Accumulators," were translations from our esteemed contemporary, *L'Industrie Electrique*, of Paris. We regret that references to our contemporary were inadvertently omitted.

Paris Academy of Sciences Awards.—The Academie des Sciences, of Paris, recently awarded prizes to M. Ph. Lenard and M. André Blondel. That awarded to M. Lenard was the La Caze prize for physics, and that awarded to M. Blondel is known as the Gaston-Planté prize. Lenard's work in connection with the cathode rays is well known. He was the first to prove that these rays, after coming outside the tube, can be made to excite phosphorescent bodies, light gases, discharge electrified bodies, and among other functions can traverse to various different degrees bodies opaque to light. The Paris correspondent of a New York contemporary (*Electrical World*) says that M. Blondel received his prize for his work in electricity. He has given a great deal of attention to alternate current work. In 1891 he determined automatically, and by a continuous process of tracing, the curves of tension and currents, and indicated for the first time the method of tracing them by photography, and in this way permitted at the same time the analysis of the phenomena, of which the alternating current arc is the seat, particularly in directly demonstrating the fact that a currrent of particles is directed from the positive toward the negative carbon; it appeared even to measure the velocity of their passage. But the most important result was the realisation of a new type of apparatus, the oscillograph, capable of transmitting to a mechanical system the exact law of variation of currents with time. He also investigated such matters as the methods of coupling alternators, a theory of synchronous motors, the use of polyphase current, the discussion of methods for measuring the power and efficiency of machines, &c. He has likewise made a special study of the electric arc. The absence of difference of phase between the current and the E.M.F. at the terminals of an alternating arc led him to think differently from the opinion widely held since the time of Edlund, that there does not exist in the arc any inverse E.M.F. analogous to that of polarisation. An ingenious method recently applied to the continuous current arc seems to confirm this conclusion, and demonstrate that the arc is equivalent simply to a resistance. M. Blondel, in his position of engineer attached to the lighthouse service, studied the photometric properties of the arc, and has undertaken a long series of experiments, which have already led to useful improvements in the apparatus of French electric lighthouses.

Coherers.—M. Branly has recently (C.R. 125, p. 939) repeated and extended some of his original experiments with discontinuous conductors described in *La Lumière Electrique*, May and June, 1891. He had found that the most sensitive substances were those which showed on the galvanometer a very feeble conductivity. This condition was produced, in many cases, by applying a pressure of 50 to 100 grammes to a layer of filings 1 to 2 mm. in thickness, contained in an ebonite cup between two metallic electrodes. Using mixtures of metallic powders and insulating substances, he found that the sensitive condition could only be obtained by the application of enormous pressures. In practice the sensitive condition is obtained by pressing the metallic layer in a small ebonite chamber between two electrodes, one of which is actuated by a screw, till a small deflection is shown on the galvanometer. It is sometimes difficult to limit the deflection to a few degrees of the scale, but in case the deflection is too great, it can always be brought back to zero by gentle tapping. As formerly, Branly sorts his powders by sifting; the higher the conductivity of the metals, the smaller the filings are made. Many metals and alloys have been found to give good results. In giving a list of metals suitable for coherers, it should also be stated what thickness of layer is best, and even the age of the layer should be stated. A great variety of mixtures of insulators and filings have been found to answer, viz., resins and filings, gumlac and filings, balsams and filings, &c. These mixtures are sometimes made up in the form of pastilles 1 mm. thick, and 2 to 3 mm. in diameter; sometimes it is convenient to form films with filings and collodion, gelatine or celluloid. These pastilles or films are placed between two metallic electrodes and pressure applied by screw till the galvanometer begins to deflect as already described. The intensity of the tapping back blow ought to be regulated. The best E.M.Fs. to employ have been found in some cases to be from $\frac{1}{20}$th to $\frac{1}{10}$th volt. Mixtures have been discovered which recover without tapping back.

The Kinetic Motor.—One is so accustomed to hear of electricity duplicating all other power agencies on American tramways, that the Dodge motor, albeit only a modified form of steam motor, comes as something of a surprise. Nevertheless, we do not doubt that there are occasions where its use may be advantageous. This new motor is on general principles much the same as the Lamm-Francq system. The kinetic system, according to the *Railway World*, to whom we are indebted for the account, is made an addition to the car, and consists of a small locomotive type double cylinder engine and a hot water storage boiler. There is on the roof a tubular air condenser similar to those used in this country. At the central station water is heated to about 380° F., which corresponds with a pressure of 200 lbs. Each car is filled up with 275 gallons, and this represents 50 horse-power (50 horse-power-*hours* we presume). To balance radiation losses, a fire-box is provided and supplied at the central station with a pan of anthracite coal, which is sufficient to keep up pressure on the longest trip. In this system the driver has a power supply to call upon at once, and his duties are no more severe than those of an electric carman. Steam from the boiler is dried by the passing of the pipe through the flue and smoke box. The cylinders are 9″ × 10″, and are fitted with ordinary link motion. Pressure is reduced through a reducing valve to suit the load requirements; speed is regulated by the link motion, and the car can be handled from each end alike. The wheels are 30 inches diameter. The driver controls the engine by means of two concentric hand wheels on a vertical post and rapid reversal of the motor can be made. A safety valve discharges any possible excess of pressure into the condenser, and in winter the exhaust is used for car warming. Nothing is visible to differentiate the car from an electrically-driven car, and there is probably a fair opening for these cars in outlying districts. They have been tried on the West Chicago Railway, the Babylon, Long Island line, and a branch line of the New York and New Jersey Railroad, the grades on which latter line, are long and heavy, but a kinetic motor on this line hauled a 33 tons trailer for a consumption of water only 35 lbs. per car mile. Speeds of 12 to 30 miles an hour have been made, and runs of 20 miles with one charge of boiler and furnace. An ordinary single truck motor car weighs 28,000 lbs.

This Year's B.A. Meeting at Bristol.—The next meeting of the British Association for the Advancement of Science will be opened at Bristol, commencing on Wednesday, September 7th. The president elect is Sir William Crookes, F.R.S., V.P.C.S. The vice-presidents elect are:—the Earl of Ducie, the Lord Bishop of Bristol, Sir Edward Fry, Sir Fredk. Bramwell, the Mayor of Bristol, the Principal of the University College, Bristol, the Master of the Society of Merchant Venturers of Bristol, John Beddoe, Esq., M.D., F.R.S., Prof. T. G. Bonney. Prof. A. W. Rücker is the general treasurer; Prof. Schäfer and W. C. Roberts-Austen are general secretaries, and Mr. G. Griffith is the assistant general secretary. The local secretaries for the Bristol meeting are Mr. Arthur Lee, J.P., and Mr. Bertram Rogers, the local treasurer being Mr. J. W. Arrowsmith, J.P. The presidential address will be delivered on the Wednesday evening, and the concluding meeting will be held on September 14th. Prof. W. J. Sollas, M.A., F.R.S., and Mr. Herbert Jackson will deliver the two evening discourses. The presidents of the various sections are: Section A, Prof. Ayrton; B, Prof. Japp; G, Sir John Wolfe-Barry. There is to be an international conference on terrestrial magnetism and atmospheric electricity associated with Section A, under the presidency of Prof. Rücker. An interesting feature of the Bristol gathering will be the formal opening of a Cabot memorial tower on September 6th by the Marquis of Dufferin and Ava. It was from Bristol that, in the year 1497, Cabot sailed to discover the mainland of the American continent.

Proposed Technical Institute for Hammersmith.—The *London Technical Education Gazette* says a movement is on foot in Hammersmith for providing a technical institute adequate for the needs of the district. The Vestry has offered a site next the Vestry Hall, and subscriptions will probably be obtained.

Electric Locomotives at Terminal Stations.—Although the day when the electric will supplant the steam locomotive on trunk lines may be quite remote, it is, says the *Scientific American*, steadily encroaching upon its domain in certain branches of locomotive work. The latest evidence of this comes in the shape of an announcement that the handsome Union Depôt at Boston is to make use of electric locomotives, and that no steam traction will be used within a mile of the station. The steam locomotives will bring their trains up to the electric yard, where they will be picked up and brought in by the electric locomotives. Outgoing trains will be similarly handled, being picked up by the steam locomotives at the limits of the electric yard. The proposed scheme is an excellent one, and could be adopted by the existing terminal stations to great advantage. Though it might involve a slight delay and greater cost of operation, the gain to the travelling public and the locality surrounding the great terminals would be valuable in many ways. The handsome terminal structures themselves would be healthier and more cleanly. Any traveller with an eye to the artistic, must have noticed how speedily the fresh painted ironwork of such a terminal as the Grand Central Station in New York, or the Pennsylvania Railroad Station in Philadelphia, is begrimed by the gases from the locomotives. With the substitution of electricity, the handsome train shed roofs would preserve their proper colouring, and the light graceful effect of their ironwork indefinitely. In the yards, moreover, the noisy exhaust of the switching engines would give way to the quiet hum of the motor—a change devoutly to be wished by the residents of the adjoining districts, who would, at the same time, be rid of the smoke and ashes that add their quota to the general inconvenience. When the approach to the terminal is in tunnel, as in many of the European cities, and here on Manhattan Island, the purifying of the atmosphere, due to such a change, is too obvious for comment. Before leaving this subject, says our contemporary, it should be noted that an electric switching locomotive has just made a successful trial on the Hoboken Shore Road, New Jersey. It has been built for hauling heavily loaded freight trains between the railroad terminals and the wharves of the trans-Atlantic liners at Hoboken. The locomotive, which is eight-wheeled, develops a total horse-power of 540, on four axles, each motor being of 135 horse-power. The substitution of electric for steam traction will prove a great boon in the populous district affected by it.

Electric Welding.—The Manchester Association of Engineers, on 12th ult., discussed various topical engineering questions. One of the questions, as given in the *Practical Engineer*, was:—"Can defects in iron castings be electrically welded?" Mr. Kelsall said if the attempt he witnessed at a large foundry in Bolton was any criterion, he should answer "No." Everything was arranged in splendid order. A piece had been broken off the edge of a segment of a large pulley, and an attempt was made to fill this up. The soft metal used, which was fused with the cast-iron, was found, immediately it was cold, to be so hard that it could not be dressed. During the melting of the two irons—the cast-iron of the pulley and the added iron—the latter became charged with combined carbon from the graphitic carbon of the cast-iron, so that it could not be dressed owing to the intense heat, the graphitic carbon, which was only mechanically mixed in the cast-iron, becoming converted into combined carbon, and making a steel harder than any steel could touch. Mr. Rae mentioned a case of the successful electric welding of a large broken fly-wheel. The president (Mr. Henry Webb) said he knew of cases of steam cylinders, calender bowls, &c., which were effectually welded, but which would have been rejected had not this operation been performed. Electric welding had saved many expensive castings from being thrown into the scrap heat. Another question was, "What is your experience of steel castings after electric welding?" Mr. Daniels said his experience was that the parts in which the castings had been electrically welded were very hard. These hard places were very difficult to overcome. Mr. Kelsall observed that he saw no reason why steel castings and forgings should not be very successfully electrically welded. The theory he had given as the cast-iron did not effect the present question. In welding steel they used metals of almost an exact equality—say steel carbon, ·50 per cent.—whereas in cast-iron they might have as much as 3 to 4 per cent. graphitic carbon to act upon. There was, however, still one rather objectionable point, and that was, they could not always get the appearance of the surface alike after tooling, different shades being shown. Otherwise, he had seen very good results, and at some works electric welding was generally adopted for castings and forgings without any detriment. Mr. Butterworth related an experience he had had, which went to show that the electric welding on some steel pistons was very superficial, and that it caused warping. Mr. Hodson mentioned cases in which he had sent back steel castings to the maker, but which had been electrically welded, and then passed inspection. There had been no difficulty in machining after the welding. The electric welding of steel by people who were experienced in the operation was a perfectly satisfactory process. The president said steel castings and forgings, and iron, too, could be electrically welded most successfully. A good firm, who had proper appliances, would do it well, and those who had made a study of cast-iron thought it could be electrically welded, but not quite as well as steel forgings or castings.

"Made in America."—The New York *Electrical Engineer* says:—"In a letter addressed to the *Iron Trade Review*, Mr. Andrew Carnegie, in a brief but convincing manner, shows that a shipyard built in or near New York Harbour, and properly equipped and managed, ought to be able to compete with any similar establishment in any part of the world. As Mr. Carnegie points out, we can produce steel more than 25 per cent. cheaper than at Glasgow, for example, while as to cost of labour, the most modern appliances, even at higher rates of labour existing here, would reduce this item below that prevailing abroad. Mr. Carnegie is anything but a dreamer, and if confirmation of his proposition be desired, the electrical arts will furnish an excellent example. As to American electric railway apparatus in Europe, that has taken so firm a position that it will be difficult to dislodge our products permanently, if at all, in the future. It may be urged that our experience in electric railway work gave us an advantage of which we have reaped the benefit. Granted for the sake of argument. But how does this explain the continued and increasing shipment of dynamos and motors, circuit breakers, &c., to Europe from our shores? Only recently we were permitted to glance at a list of foreign orders in the works of one of our well-known manufacturers—a list covering page after page of various types of machines and apparatus. But what struck us most was the fact that the machines ordered were not merely for fan motors and the smaller sizes, but ranged all the way up to 60 H.P.! We must confess that the showing surprised us. The meaning of it appears plain when one considers, first, the cheapness of our raw material, iron and copper; and, secondly, the perfection of methods of manufacture, of which machine work is the dominant factor. That this is probably the true solution of the question finds further confirmation in the fact that an able American electrical engineer will shortly leave for Germany to design a line of dynamo-electric machinery for a firm in that country, on the American system of manufacture. Reduced to a plain proposition, Europe is still building dynamos, while we have long since manufactured them. We believe that the lead taken by America in this respect will be maintained for a long time to come, while, on the other hand, our cheaper raw materials will always give us an advantage which ought to be of a lasting nature."

Lectures.—Before the Royal Scottish Society of Arts at Edinburgh on 28th ult., Mr. G. K. Grieve read a paper on "The Comparative Cost of Gas and Electricity as Sources of Light, Heat, and Power."

Prof. Barrett delivered a lecture on "Electric Tramcars: Their Propulsion and Lighting," at the Royal College of Science, Dublin, on Monday.

Before the Chesterfield and Midland Counties Institution of Engineers at Derby a paper was read last Friday by Mr. W. Maurice on "Electric Blasting," this being Part III. of a series of five papers on the practical application of electric blasting in mines. A discussion followed. A paper was then read by Mr. L. W. de Grave on "Photographs of Electric Detonators."

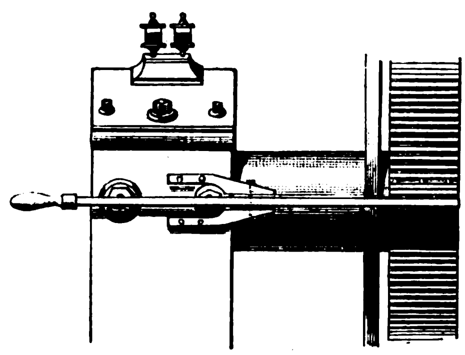
Induction Coils.—A writer in the *English Mechanic* recently asserted that the working of induction coils, when used for generating Röntgen rays, may be very much improved by increasing the capacity of the condenser. To illustrate his point, he describes the following experiment made with a coil by a French maker:—"The coil was a *perfect* one, by an excellent French maker, that is to say, *needed* no amelioration, *primâ facie*. Though of rather small size, it gave not only the 6-inch spark it should theoretically give, but very nearly 6¾ inches, and several interesting chirurgical cases were radiographed by the instrument. Wishing to try the extreme output of the small coil before buying a stronger one, my friend *doubled* the already voluminous condenser by a roughly made independent one of 100 tinfoil, not even placed in a basement, but left open next the existing one. He pressed the conduction wires upon the foil poles *by an ordinary iron weight*, and connected the improvised condenser in parallel with the constructor's one, by winding the two conductors round the spring pillar and the contact pillar respectively, so that during the experiment the wire could be connected or loosened *ad libitum*. I *saw* the experiment made, and stated, to my great astonishment, that the same Crookes tube gave nearly twice as much light upon the screen with the two condensers as with one. A bad tube giving a bad and much too intermittent image of the bones, gave immediately a sharp and permanent one. The effect of the additional condenser had been to reduce considerably the sparking at contact break, and to utilise better the extra current therefore. Time of exposure for a very strong radiograph of the hand-link is now *10 seconds* with the small 6-inch, and a mercury or some other costly or complicated contact breaker is useless." It does not follow from this that the working of every coil will be improved by increasing the capacity of the condenser. The condenser of this coil, even though made by "an excellent French maker," may have been too small. The best capacity for a condenser should be determined by experiment, and should be different for different kinds of breaks. The effect of making the condenser larger than the normal will be to reduce the sparking at the break (as the experimenter found), but also to decrease the E.M.F. and current in the secondary. The frequency of the intermittent discharges from the secondary will also be reduced. It is possible, however, that the best size of condenser may be different when different work is performed; so it might be worth while to try varying the condenser, and comparing the effect on the Röntgen rays emitted. The whole question of the working of coils and Röntgen tubes is still too indeterminate to permit of dogmatising on the subject.

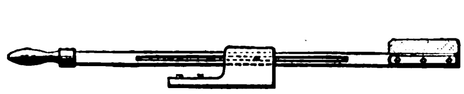
Crystal Palace Company's School of Practical Engineering.—The certificates awarded by the examiners for the Easter Term were presented to the students on Wednesday last (6th). Sir Henry C. Mance presided on the occasion, and in the course of a very appropriate and interesting address referred to the great facilities now afforded for technical education, as compared with the time when he himself commenced his career. Greater advantages, however, entailed more weighty responsibility, and led to increased emulation and competition. And this not only amongst ourselves as a nation, but we had to hold our own against foreign rivals. He mentioned the fact of the contract going to America for the machinery for the great Central London Electric Railway as a warning in this connection. If trade unionism had anything to do with it, he hoped that recent experiences might lead to the removal of that obstacle. He concluded with a few words of advice to the students, urging upon them to have a definite aim in life, and to endeavour to get early into a groove affording work of a kind that will prove a pleasure and not a drudgery. If there be such a thing as luck, and if, as it is said, it knocks at every man's door once in his lifetime, it is of the utmost importance to be in every way prepared to take advantage of the occasion when it offers.

United States Exports.—The *Electrical World* says that the value of the instruments and machinery exported from the United States for scientific purposes during 1897, was $3,054,453, which was an increase of half a million dollars as compared with the 1896 exports.

Electric Lighting Plant Required for Australia.—In our issues of 11th and 18th of March the Council of the City of Hawthorn, a rising suburb of Melbourne, Australia, invited tenders for electric lighting plant. We have received copies of the specifications, and shall be glad to show them to tenderers. The city appears to be in a sound financial condition, having a total debt of only £35,000, or £1 15s. per head of the population. Its revenue from a General Rate of 1s. 9d. in the £ on the property valuation is £15,200 a year. At the present the Council propose to provide for one or two of its main streets only at an estimated cost of £8,000, and if the scheme meets with general favour it will in all probability be extended over the whole of the municipality, comprising some 3 square miles, at a cost estimated at £40,000. The central station will be located within 1½ miles of the most distant light, and the plant now desired is to provide 50 arcs of 2,000-C.P., public, and an equivalent of 40,000 C.P. incandescent, private, with a complete unit in reserve. The Council are willing to consider any scheme that may be submitted, other than that comprised in the specification, provided it be complete in itself.

Method of Sand Papering Generator Commutators.—A novel appliance for sand papering the commutators of generators has been devised by J. D. Lynch, chief engineer of the power station of the Hestonville, Mantua, and Fairmount Passenger Railway Company, of Philadelphia, and is used in that station. It is designed, says the *Street Railway Journal*, to avoid the necessity of holding by hand a piece of sand paper against the commutator, a very tiresome operation. The device consists of a bracket of wrought-iron, ⅜-inch thick, held against the pillow block of the engine by





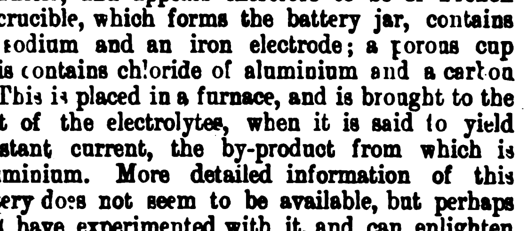
four lag screws. Inside this bracket a long iron bar with forged lever and slot running almost its entire length is held by means of a bolt. The sand paper is fastened to a wooden block at the end of this bar. The method of holding the bar in the bracket keeps the sand paper in a plane at right angles to the diameter of the commutator, so that the surface of the latter will always be flat. At the same time the pressure can easily be regulated by the handle. The commutators in this station run very smoothly and without sparking and evince great care on the part of the engineers.

The Action of the Electric Current upon some Alkaloids.—It seems that the use of the electric current provides a means for producing certain chemical substances, the production of which would otherwise involve complicated chemical reactions. As a short-cut to obtaining new decomposition products, the electrical method presents many advantages. Some examples of these are given by Herbert Pommerehne (*vide Arch. Pharm.*, 1897, No. 235, pages 364—368). He states that caffeine, when decomposed by the electric current, yields amalic acid, formic acid, ammonia, and methylamine, whilst morphine, when submitted to the same treatment, gives rise to oxydi-morphine and quinine to thalleio-quinine.

Electrical Features at the Alexandra Palace.—At the Alexandra Palace, which opens to-morrow, there are several electrical features of interest. The electric railway, to which we have already referred, is being laid down by the Imperial Electric Light and Power Company, in conjunction with Messrs. Wandruszka & Co., of Berlin. The cars are expected to be running on Friday. The power house, which faces the east entrance to the Palace, contains two sets of generating plant. The trolley system is employed, and the cars are built in the American pavilion style, for 60 passengers each. Their speed will be from 8 to 10 miles an hour. As this is the only instance of an electric trolley tramway either in or near London, it should have an educational influence both upon the public and the guardians of its interests, the members of the London County Council. The lighting arrangements are, of course, electrical. The main hall is lighted by arc lamps, and the lakes are electrically illuminated for firework displays. Electric motor cars will ply about the park. Messrs. Taylor & Field, of Westminster, are acting as consulting engineers for the whole of the electrical arrangements.

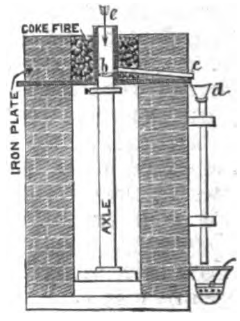
Aluminium as a By-Product of a Battery.—Judging from conversations with some experts on the subject of electro-chemistry, it appears, says the New York *Electrical World*, that it is not generally known that a battery was invented quite a number of years ago which yielded metallic aluminium as a by-product. The following meagre notes, which were made some 15 years ago, may, therefore, be of interest. The primary battery is known as that of Lacassagne and Thiers, and appears therefore to be of French origin. A crucible, which forms the battery jar, contains chloride of sodium and an iron electrode; a porous cup placed in this contains chloride of aluminium and a carbon electrode. This is placed in a furnace, and is brought to the fusing point of the electrolytes, when it is said to yield quite a constant current, the by-product from which is metallic aluminium. More detailed information of this curious battery does not seem to be available, but perhaps some readers have experimented with it, and can enlighten those interested in the subject. As it has been known a number of years it is not unlikely that practical difficulties are involved in its use.

An Ingenious Form of Armature Cradle.—The accompanying engraving, taken from the *Street Railway Journal*, shows a novel form of armature cradle or truck employed in the Glenwood shops of the United Traction Company, of Pittsburg. The special feature of this truck is that it is equipped with projecting forks or rests, so that it will pick up armatures when the latter are resting on the floor, saving in this way the labour of raising the armature by hand or tackle. The armature can then be drawn to any point desired in the repair shop. The truck is simple in



construction, and can be made by any blacksmith. The handle is about 5 feet in length. The United Traction Company is also employing an efficient kind of sand-box hose. The usual hose, of course, is of rubber, and is satisfactory in warm weather, but in winter often becomes clogged by frozen mud. In place of rubber hose, the United Traction Company is using a tube of coiled steel wire, which, naturally, is just as flexible as rubber, and has the additional advantage that when it becomes clogged, it can be stretched three or four times by the hands, which breaks up any lumps of frozen mud which it may contain. The tube is japanned, to prevent rusting.

Casting a New End on an Axle.—A writer in the *Street Railway Journal* recently gave the following illustration, showing a method of casting a new end on a car axle. The object of casting the end in this form was for experimental purposes. A brick wall was built up and around the axle as shown in the sectional view. The lower end of the axle rested upon a firm base also of brick. A collar was set-screwed to the axle as shown and a plate iron disc set in the brickwork just above. The hole in the disc was the same size as the outside diameter of the axle, and the axle was held in position by this means. The plate formed the



bottom support of the mould, *e*, also the bottom of the fire chamber. Previously to adjusting this mould, a coke fire was made in the chamber and the end of the axle, *b*, was brought to a high heat. Then the fire was drawn, all foreign matter removed from the end of the axle, the mould put in place, a new coke fire made around the mould and the hot metal poured in as the arrow indicates. There was a drain at *c*, leading from the bottom of the mould, through which the hot metal escaped to a ladle through the funnel, *d*. This was kept up until the hot metal softened the end of the axle, *b*, when the outlet was plugged and the mould filled. After cooling, and removing the axle, the point of union of the two metals was turned down and tests proved the axle to be as strong at that point as elsewhere.

Appointment.—We hear that Mr. T. B. Goodyear, who has been in the service of the Birmingham Tramways Company, Limited, for the past 10½ years in the capacity of assistant traffic manager and traffic manager, has been appointed general traffic superintendent to the British Electric Traction Company, Limited.

NEW COMPANIES REGISTERED.

Electric Supply Company of Western Australia, Limited (56,551).—Registered March 18th with capital £100,000 in £1 shares, to acquire the business of the Westralian Electric Lighting and Supply Company, Limited, to adopt a certain agreement, and to carry on the business of electricians, electrical and mechanical engineers, mortar and artificial stone manufacturers, coal, coke, and fuel merchants, &c. The subscribers (with one share each) are:—E. K. Muspratt, Seaforth Hall, Seaforth, near Liverpool, gentleman; J. B. Atherton, Manhattan, Gateacre, near Liverpool, manufacturer; J. E. Pearson, 63, Catherine Street, Liverpool, gentleman; W. H. Edwards, 4, Olive Street, Wavertree, Liverpool, merchant; D. L. Chalmers, 5, Fenwich Street, Liverpool, chartered accountant; F. J. Leslie, 15, Union Court, Liverpool, solicitor; A. E. Haptie, 5, Durham Road, Seaforth, cashier. The number of directors is not to be less than three nor more than seven. The first are B. Fitch, E. K. Muspratt, J. E. Pearson, W. H. Edwards, and T. Evans; qualification, £200; remuneration £150 each per annum and £200 for the chairman. Registered by F. J. Leslie & Co., 15, Union Court, Liverpool.

F. W. Smith & Co., Limited (56,604).—Registered March 22nd with capital £5,000 in £5 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with one share each) are:—F. W. Smith, 126, Sussex Road, Southport, electrical engineer; G. F. Travis, 49, Ash Street, Southport, gentleman; S. R. Park, 32, Scarsbrick Street, Southport, iron merchant; J. Richmond, 16, Derby Road, Southport, manager; J. White, 20, Chambres Road, Southport, manufacturer; W. W. Hall, 32, Chambres Road, Southport, merchant; R. F. Stephenson, 10, Chambres Road, Southport, manager. Registered without articles of association, by the Solicitors' Law Stationery Society, Limited, 12, New Court, W.C.

Mutual Telephone Company, Limited (56,627).—Registered March 23rd with capital £250,000 in £5 shares, to adopt an agreement with the Mutual Telephone Syndicate, Limited, and to establish, work, manage, control and regulate telephonic exchanges and works for the supply of electric light, heat, and motive power. The subscribers (with one share each) are:—N. Bradley, Mosley Street, Manchester, merchant; B. Robinson, Pendleton, Manchester, manufacturing chemist; W. Lees, Fairfield, Davenport, Stockport, hat manufacturer; G. Evans, Rochdale, merchant; A. Macnair, 20, Dutton Street, Manchester, drysalter; W Thomson. Royal Institution Laboratory, Manchester, chemist; F. Scott, 33, Brasennose Street, Manchester, chartered accountant. The number of directors is not to less than five nor more than 15; the subscribers are to appoint the first; qualification, £250; remuneration as fixed by the company. Registered office, 75, Princess Street, Manchester.

Globe Electrical Advertising Syndicate, Limited (56,673).—Registered March 26th with capital £1,000 in £1 shares (50 deferred), to adopt an agreement with W. T. Bell, of one place, and to carry on the business of advertisers by means of electric light, or otherwise advertisement canvassers, and agents, electrical and mechanical engineers, &c. The subscribers (with one share each) are:—W.T. Bell, 69, Henry Road. West Bridport, lace manufacturer; W. W. Hopewell, Broad Street, Nottingham, lace manufacturer; F. B. Whitty, Pilcher Gate, Nottingham, lace manufacturer; G. Middleton, 5, Baker Street, Nottingham, secretary; L. Mosley, 230, Askwright Street, Nottingham, clerk; N. Soans, Riverley House, Hoveringham, Nottingham, clerk; H. B. Hopewell, Eldon Chambers, Wheeler Gate, Nottingham, mortgage broker. The number of directors is not to be less than two, nor more than six; the first are, F. B Whitty, W. W. Hopewell, H. B Hopewell, and W. T. Bell; qualification, £100; remuneration as fixed by the company. Registered office, Eldon Chambers, Nottingham.

Simplex Steel Conduit Company, Limited (56,684).—Registered March 26th with capital £10,000 in £1 shares to carry on the business of manufacturer of all kinds of fittings for electric wiring, metal tube manufacturers and dealers, wire drawers, electrical, mechanical, and hydraulic engineers, tool makers, &c. The subscribers (with one share each) are:—F. Wain, 252, Moseley Road, Birmingham, clerk; J. H. Rice, Clifton Road, Sutton Coldfield, cashier; H. L. V. Pryse. Surrey House, Leamington, solicitor; H. R. Hodgkinson, Norwood House, Erdington, Birmingham, solicitor; H. C. Silk, Alcester Road, King's Heath, Birmingham, clerk; H. G. Chambers, Frederick Road, Aston, Birmingham, clerk; B. Smallwood, 84, Popular Road, Edgbaston, clerk. The number of directors is not to be less than two nor more than five. The first are H. Huggins, F. Huggins, and C. Middleton; qualification, £200; remuneration as fixed by the company. Registered by Waterlow Bros. & Layton Limited, Birchin Lane, E.C.

Improved Telephone Patents, Limited (56,698).—Registered March 28th with capital £300,000 in £1 shares, to adopt an undescribed agreement, and to acquire, manufacture, adapt, prepare, alter, improve, repair, use and deal with any materials, machinery, tools, or things connected with telephones, telegraphs, or other means of communication. The subscribers (with one share each) are:—J. H. Cuthbert, 58, Beversbrook Road, Tufnell Park, N., accountant; W. E. Elmslie, 20, Abchurch Lane, E.C., solicitor; A. E. Seamer, 7, Park Place Villas, W., clerk; J. L. Cooper, 6, Union Road, Tufnell Park. N., accountant; J. Perry, 175, Essex Road, Islington, N., clerk; H. Adams, 111, Mayall Road, Herne Hill, S.E., clerk; H. I. Bethell, 128, Beresford Road, Hornsey, N., clerk. The number of directors is not to be less than three nor more than seven. The subscribers are to appoint the first. Qualification, £100; remuneration, 5 per cent. of the net profits divisible. Registered by E. A. Foster, 6, Great St. Helen's, E.C.

Motor Omnibus Syndicate, Limited (56,718).—Registered March 29th with capital £6,000 in £1 shares, to acquire Patent No. 21,302, of 1896, to carry on the business of electricians, engineers, machinists, fitters, founders, millwrights, &c., and to construct, purchase, equip, maintain and work omnibuses, vans, steamboats, tugs, &c. The subscribers (with one share each) are:—E. H. J. C. Gillett, Hunworth Road, Hounslow, engineer; W. R. Manning, St. Maur, Henderson Road, Wandsworth Common, surveyor; C. Hayles, Perivale Lodge, Hounslow, coal merchant; A. V. England, Bank House, High Street, Hounslow, bank manager; W. B. Hurt, 78, Cicada Road, Wandsworth, S.W., clerk; R. A. Burrows, 17, Unwin Mansions, West Kensington, gentleman; H. G. Rivington, Coniston, Epping, Essex, gentleman. The number of directors is not to be less than two nor more than five; the first are A. V. England, C. Hayles, and W. R. Manning. Qualification of the first directors £50, of others £100; remuneration as fixed by the company. Registered office, 27, Chancery Lane, W.C.

Ernest G. Denner & Co., Limited (56,777).—Registered March 31st with capital £5,000 in £1 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of electrical apparatus. The subscribers (with one share each) are:—E. Denner, 5, Binfield Road, Sheffield, electrical engineer; M. Nicholson, 156, Steade Road, Sheffield; W. Haslam, 29, Spencer Street, Chesterfield, clerk; G. Smith, 1, Attercliffe Road, Sheffield, licensed victualler; W. Crake, 397, Staniforth Road, Sheffield, chemist; B. Nicholson, 156, Steade Road, Sheffield, steel melter; H. H. Ewing, 2, Plumpton Street, Sheffield, clerk. The number of directors is not to be less than two nor more than four; the subscribers are to appoint the first; qualification, 50 shares. Registered by Waterlow & Sons, Limited, London Wall, E.C.

Tyer & Co., Limited (56,760).—Registered March 31st with capital £25,000 in £1 shares, to acquire and carry on the business of an electric, telegraph, and railway train signalling engineer and contractor, carried on by E. Tyer at Ashwin Street, Dalston, N.E., as "Tyer & Co.," and to adopt a certain agreement. The subscribers (with one share each) are:—E. Tyer, Thurlow, Godalming, civil engineer; G. H. Jelfe, 35, Fairlawn Avenue, Chiswick, manager; R. W. E. Davey, 17, Walpole Road, Twickenham, clerk; H. J. Barrow, 19, Ironmonger Lane, E.C., chartered accountant; A. Barrow, 29, Heathland Road, Stoke Newington, solicitor; W. E. Tyer, 88, St. George's Square, S.W., solicitor; H. Field, St. Jude's, Maida Hill, clerk. The number of directors is not to be less than three nor more than seven; the first are to be nominated by E. Tyer; qualification, £500; remuneration as fixed by the company. Registered by Needham & Co., 10, New Inn, Strand.

Mechanical Improvement Syndicate, Limited (56,778).—Registered March 31st with capital £1,000 in £1 shares, to acquire, own, and work Provisional Patent No. 26,367 of 1897, for an improved appliance in connection with electrical illumination, and to adopt an agreement with H. Cooney. The subscribers (with one share each) are:—A. E. Box, 49, Amesbury Avenue, S.W., engineer; H. H. Farrell, 13, Silverdale Avenue, Tuebrook, Liverpool, cashier; J. H. Cheshire, 22, Johnson Street, Liverpool, agent; T. P. Martin, 16, Redcross Street, Liverpool, engineer; A. E. Boothroyd, Lord Street, Southport, cabinet maker; H. Cooney, 71, Lord Street, Liverpool, auctioneer; W. R. Carmichael, 71, Upper Stanhope Street, Liverpool, accountant. Registered without articles of association. Registered office, 71, Lord Street, Liverpool.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Direct United States Cable Company, Limited (11,597).—This company's annual return was filed on February 16th, when 60,710 shares were taken up out of a capital of £1,300,000 in £20 shares, and all considered as paid.

Yorkshire House-to-House Electricity Company, Limited (29,235).—This company's annual return was filed on February 19th. The capital is £200,000 in £5 shares (100 founders). 37,474 ordinary and 100 founders' shares have been taken up, and the founders' are considered as paid. £5 per share has been called on 18,848 and £2 per share on 18,626 ordinary shares, and £131,988 has been paid.

London Electric Wire Company, Limited (36,544).—This company's annual return, made up to February 9th, was filed on March 26th. The capital is £50,000 in £5 shares (5,000 preference); 4,188 preference and 4,597 ordinary have been taken up, and 3,860 of each description are considered as paid; £5 per share has been called on the others, and £5,325 has been received.

Madeira Electric Lighting Company, Limited (46,371).—This company's annual return was filed on February 9th. The capital is £15,000 in £1 shares, of which 10,537 have been taken up; £1 per share has been called, and £10,537 paid, and £25 has been received on 100 forfeited shares.

Malaga Electricity Company, Limited (48,076).—This company's annual return was filed on January 12th. The capital is £57,000 in 10,000 £5 ordinary and 7,000 £1 deferred shares. 9,981 ordinary and 7,000 deferred shares have been taken up, and the latter are considered as paid. £5 per share has been called on the ordinary, and £44,280 has been paid, leaving £5,625 in arrears.

Madras Electric Tramways Company, Limited (36,158).—This company's return was filed on February 26th. The capital is £100,000 in £1 (or Rs.15) shares. 64,704 shares have been taken up, and the full amount has been called and paid. £2,713 15s. 1d. has also been received on forfeited shares.

Morley Fletcher Wave Power System, Limited (48,648).—This company's return was filed on February 26th, when 694 shares were taken up out of a capital of £20,000 in £10 shares; 342 are considered as paid, and £10 per share has been called on the others. £3,375 has been paid, £150 is in arrears, and £5 has been paid on 11 forfeited shares.

National Electric Supply Company, Limited (29,992).—This company's return was filed on March 3rd. The capital is £84,943 15s. divided into 9,050 ordinary shares of £5 each, 10,850 ordinary shares of £3 12s. 6d. each, and 100 founders' shares of £3 12s. 6d. each. 10,850 ordinary and the founders' shares have been taken up, and £39,693 15s. has been called and paid thereon; £20 has been received on four forfeited shares.

Milver Portable Electric Battery Syndicate, Limited (44,003).—This company's return was filed on January 22nd, when 4,381 shares were taken up out of a capital of £22,000 in £5 shares. The full amount has been called, and £21,869 paid, leaving £36 in arrears.

International Telescriptor Syndicate, Limited (49,860).—This company's annual return was filed on March 3rd, when the whole capital of £10,000 in £1 shares was taken up; 9,993 of these are considered as paid, and £7 is in arrears.

Improved Electric Glow Lamp Company, Limited (47,636).—This company's annual return was filed on January 5th. The capital is £100,000 in £1 shares, of which 73,390 are taken up. 33,390 are considered as paid, and £39,975 has been paid on the others, leaving £25 in arrears.

Lamp Manufacturing Company, Limited (43,920).—This company's annual return was filed on January 14th, when 6,377 5/6th shares were taken up out of a capital of £20,000 in £1 shares. £1 per share has been called, and £6,377 16s. 8d. paid.

Julius Sax & Co., Limited (37,435).—This company's annual return was filed on January 17th, when the whole capital of £20,000 in £10 shares was taken up. 1,993 shares are considered as paid, and no calls have been made on the others.

Okonite Company, Limited (31,782).—This company's annual return was filed on January 24th, when 16,000 ordinary and 15,995 preference shares were taken up out of a capital of £320,000 in £10 shares; 9,332 are considered as paid, and £10 per share has been called on the rest; £225,665 has been paid, £1,015 is in arrears, and £5 has been received on five forfeited preference shares.

Newmarket Electric Light Company, Limited (44,450).—This company's annual return was filed on February 28th, when 36 shares were taken up out of a capital of £36,000 in £10 shares, and paid for in full.

Newcastle-upon-Tyne Electric Supply Company, Limited (27,997).—This company's return was filed on February 28th, when 9,259 shares were taken up out of a capital of £100,000 in £5 shares; 301 shares are considered as paid, and £5 per share has been called, and £44,790 paid on the others.

Newcastle and District Electric Lighting Company, Limited (28,022).—This company's return was filed on March 11th, when 9,918 shares were taken up out of a capital of £100,000 in £10 shares. £8 per share has been called on 5,000 and £4 per share on the others. £59,672 has been paid, and £829 has been received in advance of calls.

Northampton Electric Light and Power Company, Limited (28,640).—This company's return was filed on March 10th. The capital is £50,000 in 10 "A" and 49,990 "B" shares of £1 each. 10 "A" and 22,000 "B" shares have been taken up, and £1 per share has been called on the "A," and 17,710 "B" shares, while 10s. per share has been called on the rest. £18,594 has been paid, and £1,271 is in arrears.

CITY NOTES.

Eastbourne Electric Light Company.

In their report the directors state that the gross profit realised on the working for the year 1897 was £3,619 7s. 11d., and that the net amount available for reserve and dividend, after allowing for the interim dividend paid to June, 1897, and £400 carried to the depreciation fund, is £1,838 9s. 9d. They propose that £412 be placed to reserve, and that out of the balance left of £1,426 9s. 9d. a dividend at the rate of £10 per cent. for the half-year, making with the interim dividend paid in June, £7 10s. per cent. for the year, free of income-tax, be paid upon all the share capital of the company. This, after allowing for the interim dividend, will absorb £974 15s. and leave £451 14s. 9d. to be carried forward to next year's account. The depreciation fund now stands at £3,025; and if the proposal of carrying £412 to the reserve fund is adopted the reserve will then stand at £3,250, making a total reserve of £6,275.

The capital account shows a considerable outlay in the past year for main extensions and for additional machinery and plant, bringing up the deficit on this account to £5,553 1s. 1d.; and the directors have to provide for a prospective outlay for the next two years of at least £4,400, making a total further capital required of £9,953 1s. 1d.

The directors have had under consideration the desirability of placing the depreciation and reserve funds upon a more solid basis. The aggregate of the funds, as stated above, is £6,275, but the money is actually in use in the company's business and is not represented by separate cash.

The lamps in circuit, reckoned upon an average of 8 candle-power per lamp, number 19,288, against 16,690 at the close of 1896, an increase of 2,598 lamps for the year. The net increase of customers for 1897 was 56.

Rand Central Electric Works.

The directors state in their report that steady progress has been made in completing various installations and connecting them with the main line, and it is expected that the revenue from the constantly increasing power supply will show a satisfactory return for the current year. It must be borne in mind that up to December 31st last the central station had only been in partial operation, supplying but a comparatively small proportion of the power contracted for, and therefore the revenue derived from power supply during the past year is no criterion of future earnings. The earnings of the past year do not, however, affect the dividend payable to shareholders, because Messrs. Siemens & Halske guaranteed that the net profits available for dividend in the financial year under consideration would be at least 6 per cent. The necessary arrangements having been made with the contractors, the directors have decided to recommend that a dividend at the rate of 6 per cent. be declared for the year 1897. In accordance with the articles of association, Sir C. Rivers Wilson, G.C.M.G., C.B., the chairman of the company, and Mr. Carl von Siemens retire by rotation from office as directors, and being eligible, offer themselves for re-election. Messrs. Price, Waterhouse & Co., the auditors, also retire, and offer themselves for re-election.

Electrical Street Car Manufacturing Syndicate, Limited.

A statutory meeting of the shareholders in the Electrical Street Car Manufacturing Syndicate, Limited, was held on Friday at the works of the syndicate, Wednesfield Road, Wolverhampton. The syndicate, it may be remembered, was incorporated in December last, and the present meeting—at which there was no business for consideration—was held in order to comply with the provisions of the Companies Acts. The chair was occupied by Major Flood Page, of London, chairman of the syndicate.

The Chairman made a short statement respecting the company's prospects. He thought that the speed and success with which the new works and offices had been erected and equipped, indicated great energy and skill on the part of those of his colleagues who had directed the work. They had got excellent premises. The amount of money subscribed in cash was a little over £7,000, and there was only one very small sum in arrear. That was an element of satisfaction in starting the enterprise. They were probably witnessing the commencement of a very great advance in electrical matters, and he was sure that electric traction in the streets would in a few years cause a great diminution in the number of horses so engaged. They only required a good accumulator and good business management. The fact that Mr. Parker was engaged in the undertaking gave it an element of certainty, for chance was, he was sure, placed out of the question by that gentleman's association with the company. All over the world Mr. Parker was known in connection with electrical engineering, and they could congratulate themselves that so far as electrical engineering was concerned, the undertaking would be a success. So far as the business department was concerned, he could say—speaking on behalf of his colleagues and himself—that they would do their very best. He thought that their prospects were excellent. In four or five years' time there would hardly be a horse-drawn omnibus in the country. The London omnibus companies had incomes amounting to over a million, and they represented the business which the syndicate was waiting for. He thought that the younger shareholders present would live to see the day when that business would attain vast proportions, comparable even to that of the London & North-Western Railway Company.

A special general meeting was subsequently held on the requisition of eight shareholders, when a resolution was passed amending No. 86 of the articles of association, so as to enable the shareholders to remove any director before the normal expiration of his term of office if necessary.

The Indo-European Telegraph Company, Limited.—The directors after adding £15,000 to the reserve fund, have determined subject to audit, to recommend the payment of a dividend for the six months ended December 31st, 1897, of 17s. 6d. per share, making with the interim dividend already paid, 6 per cent., and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year. The dividend and bonus will be payable on and after May 1st next.

Anglo-American Telegraph Company, Limited.—The directors have resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending March 31st, 1898, of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, less income-tax, payable on April 30th, to the shareholders registered on the books of the company on March 31st, 1898.

Stock Exchange Notices.—The Stock Exchange Committee has ordered the undermentioned to be quoted in the Official List:—Milwaukee Electric Railway and Light Company—$603,000 additional 5 per cent. 30-year consolidated mortgage gold coupon bonds of 1926, Nos 7,001 to 7,603.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending April 1st, 1898, were £2,339 11s. 6d.; corresponding period, 1897, £2,025 7s. 10d.; increase, £314 3s. 8d.

The City and South London Railway Company.—The receipts for the week ending April 3rd, 1898, were £1,050; week ending April 4th, 1897, £1,026; increase, £24; total receipts for half-year, 1898, £14,942; corresponding period, 1897, £14,818; increase, £124.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, April 1st, 1898, were £358 12s. 3d.; corresponding week last year, £367 11s. 1d.; decrease, £8 18s. 5d.; passengers carried, 62,971; corresponding week last year, 60,701; aggregate to date, £5,152 1s. 8d.; aggregate to date last year, £5,514 4s. 9d.; decrease to date, £362 3s. 1d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending April 3rd, 1898, amounted to £1,313; corresponding week last year, £1,323; decrease, £10.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending April 1st, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company Limited, were £2,895.

MECHANICAL STOKERS.

The inventor of an American stoker, Mr. Roney, has given a brief history of mechanical stokers in *Cassier's Magazine*, in which, naturally, the hopeful side of stoking by machinery is looked upon. It is over 100 years since machine stoking was first employed, and it appears that in Great Britain the mechanical stoker has seen its largest employment, over 25,000 being stated as at work, chiefly upon the long, narrow grates of internally fired boilers. James Watt patented the first stoker in 1785, which consisted of two sets of horizontal grate bars, worked intermittently by hand levers. It is said to have been a success as a smoke preventor. It is a little amusing to see the Hopcraft Furnace of 1889 seriously described among a host of others, and its complicated construction set down as an evident obstacle to success. There never was any necessity to put forward the question of complicated construction to account for the failure of this furnace. It never was known to be a success anywhere. It never even acted in any way as it was claimed; it was hopelessly impossible from the first, and was condemned by experts from the beginning, and only one of the company's engineers had the pluck to say so, for which —but we will draw a veil; the inner history of this furnace has to be written, but the time is not yet. It forms a unique specimen of the art of company-mongering, an art which drew £180,000 from the eager public for a patent that no practical man would have passed as worth 2½d.

German stokers are rated by the author as merely modified British stokers without their advantages. Novelty in design seems, however, to have been sometimes sought in America. The Murphy is one such. It was the first distinctively American stoker, and was patented in 1879. It is applicable only to under-fired boilers, and consists of a V grate under a brick arch, fed by lateral plungers from coal hopper passages in the side walls about 6 or 7 feet long. The bars of the V grate run parallel with the slopes, which are at an angle of about 35°. At the apex is a revolving toothed bar to grind out clinker. All the sloping bars are hinged at their upper ends, and are moved by cams about an inch at their apex ends. This brings down the fire as it burns away. It is said that this machine has a good record. We can believe it, for, apart from the serious inconvenience of the lateral coal hoppers it seems well designed, but it appears only specially applicable to single boiler installations.

The general trend of American stokers, constructed as they are for use with externally fired boilers, is to the use of steeply inclined grates sloping down from the firing plates, and with the separate bars moving more or less, so as to induce the fuel to move forward and downward. The advantage of these sloping grates, is that the fire need never burn into holes, for the grate movement can be arranged to be quick enough to cause the fuel to gather and fill up the voids as formed.

Mr. Roney is in error when he states that the English Jukes grate was made with bars crosswise to the furnace. We have seen some scores of these furnaces in Yorkshire, and never saw one which had not the link belt grate exactly as illustrated in Mr. Roney's illustration of this furnace, as copied by the Babcock & Wilcox Company, of New York. As in England, underfeeding has been attempted. American underfeed stokers follow closely on the design of Holroyd Smith. As we have before stated, the patent of Mr. Roney himself includes the sloping grate idea, but with transversely placed bars which rock and form a rocking-step grate. There is a dumping grate at the lower end for cleaning purposes.

For externally fired boilers, possessing ample space and height for liberal mechanical arrangements, we cannot see how anything much better than the Roney idea can be evolved. The ability to use gravity gives the power of overcoming that worst fault of other coking stokers, the thinning out of the fires at the back ends of the bars. By gravity and grate shaking the fuel can be travelled down the slope at a speed sufficient to keep the bars covered, the dumping grate serves to clear off clinker, and, generally, the machine looks like a success on paper, and, we believe, is one *de facto*, as, indeed, is borne out by the tendency towards this type. Externally fired boilers are not so common in England, and we are, therefore, confronted in our internally fired boilers with a far more difficult problem mechanically. Our coals are chiefly bituminous, and must be burned on the coking system for perfect smokelessness, and unless there be a bridge against which to travel the fuel on the bars, so as to feed up the hollow places burned in the fire, there is always apt to be an excess of air, and corresponding reduction of efficiency. With Mr. Roney, however, we agree that the stoking of the future will be more and more by mechanical means.

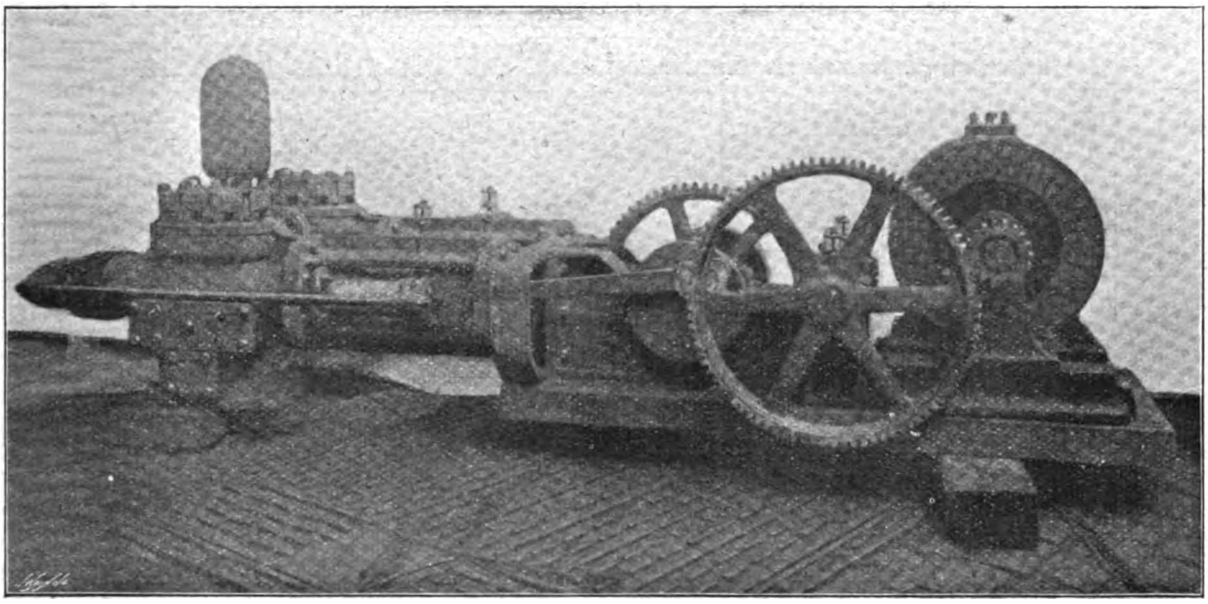

Fig. 5.

THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

The Practical Operation of Multiphase Currents. By T. Hawkins, Member. March 14th, 1898.

(*Concluded from page* 457.)

The electromotive force at the generators is 960 volts at 50 cycles, the length of the line being 835 yards. The power is transmitted through bare overhead conductors, supported on porcelain insulators. The station and line are fitted with Wurts's lightning arresters.

Figs. 5 and 5a show one of three horizontal 5 inches by 9 duplex pumps, made for the Consolidated Goldfields of South Africa. Each pump is capable of raising 200 gallons 60 feet per minute, and is coupled to a 9 H.P. three-phase motor through double reduction gearing. The speed of the motor is 1,150 revolutions per minute, with 60 cycles and 110 volts between two phases.

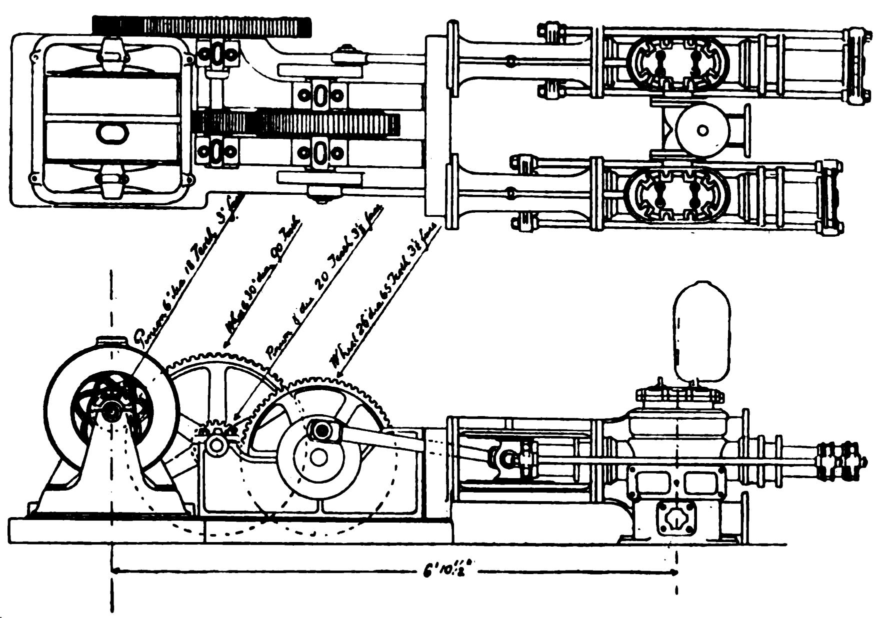

Fig. 5a.

Fig. 6 is a photograph of an electrically driven coal cutter, fitted with two 10-H.P. three-phase motors. The motors are wound for 500 volts, and are switched into circuit without any starting device. Their speed is 960 revolutions per minute, this being reduced to 9 revolutions per minute at the cutter through treble reduction gearing. The diameter of cutter wheel is 5 feet 8 inches.

This machine has been constructed for Messrs. Pope & Pearson, Limited, for use in their colliery at Normanton. The distance between the generators and coal cutters is about a mile.

The plants described in this paper have all been supplied within the last two years, and although, I am sorry to say, it is a very small amount when compared with what is being done in the United States, Germany, or Switzerland, it is some satisfaction to know that a little progress has been made in this country in the manufacture of this class of work.

Even those who do not admit of any or sufficient superiority of the three-phase over the continuous current system to induce them to take up the manufacture of the former for use in England, must acknowledge that many large and valuable orders for our colonies and elsewhere are given to foreign firms, which ought to be executed in this country, but unfortunately so little has been done here that so far we are not in a position to compete.

SOME RECENT IMPROVEMENTS IN ACCUMULATORS AND THEIR APPLICATION TO TRACTION ON COMMON ROADS.*

By J. T. NIBLETT.

Means of vehicular locomotion by the aid of some power other than that of horses is a subject that is now receiving a vast amount of attention. Not only is it of interest to electrical and mechanical engineers and carriage builders, but it has been taken into serious consideration by all those responsible for the regulation of traffic in our large towns. The subject is of such huge importance, that it not only affects those whose business or pleasure calls for some rapid and safe means of transport from place to place, but it affects the safety and comfort of the ordinary pedestrian as well. Our present system of horse traffic is open to many objections, not only from a humanitarian point of view, but from its sanitarian and economic aspect as well. The streets in our large towns would present a vastly different aspect if, instead of horses, some other means of drawing our vehicles were used.

Much attention has been given to the application of steam, petroleum, and spirits to produce the necessary motive power; but there is but little doubt that electricity will eventually supersede them all, not only on the score of economy, but owing to its freedom from heat, steam, disagreeable odour, and to the ease with which it can be manipulated.

In this communication we do not propose touching upon the numerous applications of electricity for the propulsion of tramway cars and light railways, but we shall devote our attention more especially to the subject of the electrical propulsion of vehicles on common roads by means of batteries. We shall point out some of the recent improvements that have been made in batteries suitable for this purpose, and shall then indicate in a few words how they are best employed, and the most approved methods of dealing with them. An endeavour will be made to deal with the subject in a popular manner, and all technicalities will be avoided as far as possible.

Secondary batteries may be divided into two classes, viz., those in which the active material is formed from the substance of the element itself, either by direct chemical or electro-chemical action, and those in which the chemical formation is accelerated by the application of some easily reducible salt of lead. Elements of the former type are usually termed "Planté," and those of the latter "Faure" or pasted, Messrs. Planté and Faure being the respective inventors.

The active materials in all the best known types of secondary cells, whether of the Planté or Faure pattern, is peroxide of lead in the positive element, and spongy lead in the negative. The medium through which the necessary chemical changes occur during either a charge or discharge is a solution of sulphuric acid and water. There is still much doubt as to the precise nature of the chemical changes involved in a lead sulphuric acid cell, due to the action of an electric current, and therefore this matter will not be discussed here. Enough, however, is known to enable those concerned in their commercial manufacture to construct cells of almost any electrical capacity, and capable of taking up and giving out any rate of charge or discharge. It is now usual to speak of any given type of secondary cell as being of so many ampere-hours capacity per pound of plate, or per pound of complete cell. In the latter case the precise nature of the containing vessel, whether it be of glass, earthenware, metal, or vulcanite, must, of course, be specified.

One of the earliest to introduce into this country a commercial cell of the Planté type was Mr. Epstein, and a cell bearing his name has been long on the market. Mr. Epstein has given much attention to the production of accumulators of this type, and in a recent communication to the Institution of Electrical Engineers he promised to shortly introduce an improved form of his plate, which he stated was particularly suitable for traction purposes. Such a promise, coming from one so well versed in the subject, leads us to expect a real improvement. The original Epstein plate was made by deeply grooving both sides of a lead plate. The plate, when grooved in this way, was boiled in a solution of nitric acid and water, or some similar solution. This process is said to so corrode the metal that it is easily acted upon electrolytically. Owing to the serrated nature of the plate, the active material appears to wedge itself in the narrow grooves, and does not fall out under ordinary working conditions.

The Crompton-Howell cell, which we do not hear much of now, was constructed of plates sawn from a cast mass of porous lead. We believe this material was prepared by a system of aerating the metal while in its molten condition. The resulting plate was of a highly porous and crystalline nature, and, owing to its porosity, the electrolyte easily permeated it, thus rendering the formation quite an easy matter.

A form of cell now on the market, known as the "D.P." accumulator, manufactured by the D.P. Battery Company, is also of the Planté type. The elements in this case consist of a large number of narrow strips of lead built up one above the other. By this method a large active area, enabling the cells to be charged and discharged at high rates, is obtained, while disintegration of the active material or buckling is said not to occur. As in the case of the Epstein cell, the plates are chemically treated to accelerate the formation.

The traction cell made by this company is not designed with a view

* Abstract of paper read before the Self-Propelled Traffic Association, Liverpool Centre, on March 29th.

to extreme lightness, but rather with the idea of combining durability with as little weight as possible. The containing case of this particular form of cell is of ebonite, and it contains three plates—one positive and two negative. The weight of the complete cell is about 33 lbs., and three cells are put in a crate for convenience of handling, the weight of the three thus fitted being about 100 lbs.

The capacity of each cell is 100 ampere-hours, at a normal discharge rate of 15 amperes. They can, however, the makers state, be discharged at any rate within reason that may be desired without damage to them, the only consequence being a loss in capacity as the discharged rate is increased. The makers assert that with this form of cell a current capacity of four ampere-hours per pound of plate, and three ampere-hours per pound of complete cell, is obtained.

The "Lamina" accumulator elements, as manufactured by the Lamina Accumulator Company, are made up of a series of perforated and corrugated lead strips. The method of making these plates is somewhat as follows:—Lead is received in the form of rolls of 8 to 10 inches wide, and of varying thickness of from $\frac{1}{64}$th to $\frac{1}{32}$nd of an inch. The lead is first perforated, and is afterwards corrugated by a suitable machine. After being treated in this way the lead is cut up into strips of the desired size. These strips, when built up, are encased by a sheet of perforated lead, held in position by leaden rivets, and lead-burnt at the top and bottom.

The forming process is said to take only 36 hours. As the mechanical construction of the plates is simple and strong, they are said to withstand quite well the severe work imposed upon them when used for traction purposes. The makers state that a cell of this form of construction can safely be charged or discharged in one hour. The following data of the company's "A 5" traction cell may be of interest. The containing case is of ebonite, and is of the following dimensions:—10½ inches long, 4½ inches wide, and 12 inches deep. The complete weight of the cell, with elements and electrolyte, is given as 40 lbs. The dimensions of the positive plates are as follows:—8½ inches long, 7¾ inches wide, and ⅜ths of an inch thick. The size of the negative plates are:—8½ inches long, 8¼ inches wide, and ⅜ths of an inch thick. The discharging rate of this form of cell is 20 amperes, but it may be run up to 100 amperes. The normal charging rate is 25 amperes, but this can also be run up to 100 amperes.

Faure, or Pasted Cells.

Messrs. Sellon, King, Volkmar, Philippart, Parker, Swan, and others, have each devised methods of holding active material on grids, frames, or plates. These methods, combined with Faure's original discovery, constitute that group of inventions owned by the Electrical Power and Storage Company, and are well known shortly as the E.P.S. patents. In all cases the actual forming is done by the purchasers.

Of late years improvements have been made in the original E.P.S. plates. The King-Faure plate, now much used, has a series of ledges cast upon it on both sides, and these ledges are filled in with the active material. Plates made on this principle are much thicker than those originally made, and are said to give a greater capacity per pound of plate. The accumulators made by the E.P.S. Company, and so extensively used for electric light purposes, are so well known that they scarcely need further description here. We shall, however, have occasion to again refer to this company's traction cells later on.

Since the year 1880, considerably over 1,000 applications for British letters patent have been made for improvements in secondary batteries, chiefly of the Faure pattern, and of these some hundreds have developed into fully published patents. The great majority of the suggested improvements are of a mechanical nature, and refer more especially to:—(1) Methods of accelerating formation; (2) devices for preventing disintegration of the active material; (3) attempts to construct a mechanically solid cell; and (4) means to prevent that great bugbear of all lead accumulators—the warping and buckling of the plates or grids.

It is not within the scope of this communication to investigate all the attempts made to overcome the above-mentioned difficulties, and only a few of those batteries now on the market will be considered. In addition to the improvements noticed here, much has been done in this country by such workers as Sir Edward Frankland, Messrs. Reckenzaun, Drake, Gorham, Barber-Starkey, Pitkin, Bristol, and others. On the Continent, Messrs. Reynier, Tommasi, Gadot, Hagen, Jacquet, Payen, Laurent-Cely, Pollak, and Blot are each credited with improvements; while Messrs. Brush, Eickmeyer, Ernst, Carpenter, Knowles, Hering, Gibson, Currie and Winkler, in America, have modified, with some amount of success, either Planté's or Faure's original inventions.

A form of accumulator which has been received with much favour on the Continent is known as the "Tudor." Of late years this form of cell has been introduced into this country, and is now manufactured by the Tudor Accumulator Company. The elements are not of the grid form, but consist of lead plates deeply grooved, made by being passed between a pair of suitably made rollers. The grooves in the negative plate are narrower than those on the positive. When prepared in this way, the plates are coated by electrolysis with a thin layer of peroxide, and the interstices are then filled in with the usual paste of lead oxide. The reason for treating the plates in this way is to prevent the formation of sulphate of lead at the junction of the metal holder and the active material. After the above treatment the plates are allowed to dry, and are passed through smooth rollers. This last process closes up the grooves, and tends to key the active material in.

According to Prof. Kohlrausch, who made some tests of the original Tudor cell, he found that a capacity of 1·6 ampere-hours per pound of plate was obtained by a cell of the following dimensions:—The weight of the elements was 29·3 lbs., the total active surface of the positive plate was 1·29 square feet, the amount of electrolyte was six pints. Such a cell was stated to have an integral resistance of 0·015 ohm when charged, and 0·02 ohm when discharged. The best charging rate was found to be 5 amperes, and the discharging rate 6·5 amperes. As a mean of six ordinary charges and discharges a current efficiency of over 90 per cent. was said to be obtained. We believe that since the above test, and owing to improvements made, far better results have recently been obtained.

(To be continued.)

AN ELECTRICAL HYPOTHESIS FOR THE SOLAR AND PLANETARY SYSTEMS, AND SOME OF THEIR ASSOCIATED PHENOMENA.

By DELTA.

(Concluded from page 462.)

The Cometary Bodies.

The application of the electrical hypothesis to an explanation of this erratic body* is necessarily highly speculative, but not more so than that of any other hypothesis yet propounded.

It is suggested that the rotation of the solid element of the comet is effected electrically. The rapid movement of the body in a state of erratic movement drags along with it an atmosphere which streams behind like the tail of a kite, or the steam from a locomotive; this straggling atmosphere is illuminated by the passage through it of electric energy of high intensity and frequency.

The Nebulæ.

It is assumed—in the absence of more specific data—that the nebulæ are clusters of small electrical conductors, or stars, enclosed in a common luminous atmosphere.

The same theoretic assumption applies to the spiral nebulæ, the stellar character of whose nuclei is admitted.

The electric solar high pressure energy illuminates the nebular atmosphere, enters the stellar bodies, which are assumed to be spherical polarised electric conductors and transformers, to be admitted to the interstellar and low intensity electrical ocean at low intensity.

It is suggested that the coalescence of the stellar portions of the nebulæ is the result of inter-electrical action acting in the same way that electrified particles of aqueous vapour unite to from clouds.

Shooting Stars.

It is admitted that the luminous streaks, known as shooting stars, travel constantly in the same pathway around the solar centre, their orbits of passage being very similar to those of cometary bodies.

No doubt somewhat analogous to the currents that flow in specific lines in the aqueous oceans of the earth, there will, in the great interplanetary and interstellar electrical ocean, be distinctive electrical currents of voltage, differing specifically from that of the normal, and carrying with them bodies that are outside the influences of attraction of planetary and stellar bodies, but are exposed to the luminous influences of the electrical currents emanating from the sun.

Stars.

The repulsive force of electricity varies inversely as the ratio of molecular weight, the lightest particles being driven from the great solar electrical conductor.

Each star will be, it is suggested, a small conductor, and must either have its own luminous atmosphere, or be so constituted, as to offer a resistance to solar electrical emanations, such as to set up in a portion of its sphere a temperature of bright incandescence; such a form of inferior conductor can be easily imagined, and if thought of in combination with the effect of rotation, it should produce the intermittently luminous character associated with movable stars.

The fixed stars are probably amenable to the same law, and it is likely that this incandescence effect that induces

* It has already been admitted by one astronomer that the luminous emissions from cometary bodies are largely of an electric origin.

disintegration resulting in the formation of aerolites, meteorites.

The fixed stars may have atmospheres of varying chemical character and density, and thus we should have luminous effects of varying colours coincident with the density of the stellar envelope which is illuminated by the resistance offered to the flow of solar electrical energy.

THE INFLUENCE OF STARS IN THE EXTENSION OF HIGH VOLTAGE SOLAR DISCHARGES.

A high pressure electrical discharge can be extended indefinitely—by the introduction of simple conductor spheres, in the line of electrical discharge—and it is here suggested that the myriad upon myriads of stars that photography has disclosed to us may really constitute a means by which high pressure solar electrical currents are distributed over the vast area we know as the stellar and planetary space.

The starry elements we already know have varying degrees of luminosity; the greater number do not actually emit luminous rays of sufficient intensity to be seen by the human eye, although faithfully recorded by the sensitive photographic plate.

A CORRELATIVE THEORY.

Since the date of the publication of the first and second of these articles, the journal *Electricity*, of New York, in its issue of February 16th, publishes a new theory propounded by Dr. William M. Gross, which has a certain resemblance to the theory formulated in these articles.

The Gross theory briefly defined, and in his phraseology, slightly modified, is as follows :—

He believes that electrical force is induced and not static.

Dr. Gross asserts that the earth and its atmosphere go to make up an immense armature, with that portion of space between the earth and the sun as the electro-magnet.

He suggests that the earth in revolving generates a powerful current.

He says the solar rays are vertical on some parts of the earth all the time, and that *the space between the earth and the sun is heavily charged with electricity*.

Currents of this electricity are induced out of space by the revolution of the earth from west to east. In accordance with the law of Lenz, governing electrical currents, they, the electrical currents, pass in opposite direction, that is to say, induced currents of electricity always move in opposite directions to the electro-magnetic force producing the current.

These currents are brought down to, and through the earth by the latter's centrifugal force. This force tends from the centre and towards the east; the electrical currents tend from the east and to the centre of the earth.

When the centre becomes surcharged, the current flows off at about the 70th parallel, producing the north and south winds.

His experiments with ground telephonic wires has satisfied him that the earth is full of electricity. Dr. Gross is making elaborate investigations, more of which we shall doubtless hear anon.

THE INFLUENCE OF ELECTRICAL CONDITIONS UPON ORGANIC BODIES.

The importance of the investigation into the electrical characteristics of organic bodies has already been emphasised, and W. Branly's recent contribution in December, 1897, to the Academie Française, is most opportune, and establishes a striking analogy between the effect of continuous electrical currents upon the nervous system, and upon the coherer; Branly, although not prepared to say that the coherer and the nervous actions are altogether similar, nevertheless considers that the resemblance is sufficient to form a valuable guide to the electrotherapeutist.*

The author suggests that there is some analogy between the cause and effect of Hertzian rays and the strong impulses that are occasionally transmitted between human subjects, in strong sympathy with each other, but separated by many miles.

* It is only fair to W. S. Hedley, M.D., to say that he suggested in the *Lancet* a similar physiological analogue as far back as May 4th, 1895.

The influence on organic plant life is not at all realised in the measure of its importance.*

In concluding these articles the author asks for the unprejudiced consideration of the hypothesis he has so imperfectly formulated.

We are, even now, a century of years past the time when Volta first initiated his researches into the electrical condition of the atmosphere, but little in advance of his knowledge, either in the exact knowledge of the electrical characteristics of the atmosphere or of the earth itself.

The exact knowledge of the character and proper appreciation of the all powerful influence of high voltage rays that stream from the solar fountain of electrical energy (which is the master influence in developing and maintaining organic vegetable and animal life) may permit some of us to find means of control and diversion of such energy for the benefit of man, and especially in the removal of nervous stress. The tendency of modern *fin de siècle* civilisation is more and more in the direction of the suppression of the animal in favour of the mental energy. In the train of this tendency, and constituting one of the baneful effects of modern life, is the increase of diseases of an almost entirely nervous character; and the individual, who is compelled to follow in the mad rush, is becoming more and more susceptible to the varying conditions of his electrical environment, and, therefore, the demand for more light, is not merely the product of a desire for scientific research, but it is based upon motives having a far more serious *raison d'être*.

Given this enlightenment, then the necessity to grope in the gloom of uncertain knowledge, prompting hypotheses of more or less speculative character, however logical they may be, will disappear.

If the author has not sufficiently curbed his imagination in building up the electrical theory applied to a field of immeasurable dimensions, and one that must necessarily be of a more or less highly speculative character, he trusts that the contribution may lead at least to a proper recognition of the importance of correlating the day by day changes in the electrical condition, and the other physical changes of the atmosphere with that of the substrata of the earth, and in geographically well-distributed centres.

If ardent investigators would devote their serious attention to the exploration of this comparatively unknown field of scientific research, they would confer inestimable advantages on their fellow men.

Compared to this field of research, the importance of the exploration of Arctic and unknown territorial regions becomes puerile. There is no reason why practical science should not be able to provide means for testing the electrical condition of both the atmosphere and the earth at a distance of even five miles below or inside, and 10 miles above or outside the surface of the earth.

The competent and adequate exploration of the electrical mystery land offers far more prizes than can be easily imagined, and the fruit of such research may not only eventually command the ready and artificial discharge of clouds and the fall of rain, but it may permit the establishment of conditions that may prevent the influence of effects injurious to human life and happiness.

A society formed from the ranks of physicists, electricians, chemists, and from the medical fraternity, along with experts in astronomy and meteorology, would find ample scope for work in the field of research outlined. That this society will be formed, is the ardent hope of "Delta," and he trusts is also that of your readers.

* "I have been applying now for nearly a year electrical radiation for the purpose of improving our native wheats. I pass them through the terminals of a Tesla apparatus and find that the instantaneous exposure has a marked effect upon the germination and upon certain important functional features of the grain. There is a violet radiation round the wires, but *nothing visible* when the *grain passes* them. The defects which this treatment go farthest towards remedying exist in Scotch wheat and do not exist to the same extent in wheat which are grown *with more sunshine*, and it is an interesting question whether these differences are caused, not so much by the variations in the amount of sunshine as by the variations in the *quantity of violet rays reaching the growing wheat*. However that may be, I think it points in the direction indicated by your paper, that the electrical radiations from the sun play a most important part in the vegetable world."

Letter bearing date March 3rd, 1898, received by the author.

THE TELEGRAPH TROUBLES.

THE CLERKS' POINT OF VIEW.

BY CHAS. H. GARLAND.

(*Concluded from page* 386.)

DURING the progress of these papers it has been sought, by the free use of quotations, to show how far the ideals of State employment, as formulated by politicians, economists, and even barristers, of all shades of political bias, differed from the actual conditions which exist to-day. Whilst the whole country seems to be fast progressing towards a more real democracy, whilst the pressure of public opinion is forcing Ministers to proclaim themselves in favour of the most advanced and generous principles of State employment, the permanent Civil Service of the Crown remains the stronghold of a labour policy that, viewed in the light of present-day economics, is absolutely reactionary. The rights enjoyed by ordinary citizens are, in many instances, taken away from State servants, and this deprivation is thought to be justified by reference to certain illusory benefits, which, in many instances, exist only on paper. Thus the statement of Mr. Arnold Morley as to the "right to combine" among postal servants may be regarded as a sop to the Cerberus of public opinion. Any postal servant knows that the picture there painted of the privileges enjoyed by the various unions bears not the slightest resemblance to the actual state of affairs. What did Mr. Morley say? In a letter addressed to Mr. Murray Macdonald, M.P., on April 1st (an ominous date), 1895, the following words occur: "The officers of this Department are at liberty to combine in any way they may think proper. All the privileges which trade unions enjoy, and, in my opinion, rightly enjoy, are thus accorded to the unions of postal officials." The uninitiate would gather from this that the most complete liberty of combination, as at present understood, was enjoyed by Post Office servants. Yet this is far from being the case. The publicly-proclaimed rights are cut down to mere nothingness by restrictive regulations, which are defended on the ground of discipline—a defence which would not protect a private employer from censure. During the recent debate in the House of Commons on this subject, the point at issue was obscured by references to dismissed officials, and the real principle was lost sight of in a profitless discussion of a disciplinary measure of Sir James Fergusson. Although the principle of the right of combination may be said to be involved in the defence of this measure, such is the nature of Parliamentary debates, that the House generally "cannot see the wood for the trees." The truth is, that although unions are perforce tolerated in the Post Office, they are not officially recognised by the Department.

The officials of the various organisations are not recognised as such by the Department, their communications are not recognised as representative of their membership unless backed by the signatures of their members, their representations are only received at all on condition that they themselves are suffering from the grievances complained of, and they are never consulted by the Department when changes are contemplated or disputes are to be settled. Again, the union officials are regarded as rebels, and it only requires a brief survey of the recent agitation history to show that danger, difficulties and disfavour accompany the tenure of office in the unions of postal officials. Men have even been discharged for the ventilation of grievances which have afterwards been remedied, and the complaint thus justified. These things are hard to believe, but are nevertheless true, Mr. Morley notwithstanding. Official returns have been issued recently, tending to show that the Department has improved the condition of its employés, and that the ratio of the wages bill to the receipts has increased. It has not been contended that these improvements were not necessary. In many cases, as I have pointed out, they are illusory; but they have never, in one single instance, been initiated by the Department. They have all been won by the men themselves in the teeth of opposition, indifference, discouragement, and personal danger.

Instances innumerable could be adduced in support of these assertions. It is difficult to say where the blame lies, unless one attributes it to so impersonal an entity as the system. This administrative system, "iron-bound with red tape," forms an impregnable rock against which successive Postmasters-General beat themselves in vain; but it is high time that heroic measures were taken to change it. There is a tendency for the State to take charge of much more of the business of the country than at present, and if as each great industry is successively taken under its wing, the workers are to be deprived of the benefit of the common laws by restrictive regulations, we shall soon find ourselves sliding down a steep gradient towards a bureaucratic tyranny which is terrible to contemplate. In France the climax of this condition of affairs is fast approaching. By the same specious reasoning the State justifies the denial to its servants of the rights of combination assured to all other workers by the law of March 21st, 1884, and as the various industries of tobacco preparation, match-making, railways, education, telegraphs, telephones, letter-carrying, and the multifarious duties undertaken by the French Post Office come into the hands of the State, the employés are deprived of this important part of their civil rights. *L'Eclair* of August 29th, 1896, commenting on the matter, makes some remarks which have a peculiar appropriateness to the present position in England. "Why are State servants thus denied the common rights?" it asks. "Because they are civil servants, which amounts to saying that instead of being paid by some sort of commercial employer, a simple citizen like themselves, they are paid by His August Majesty the State. And the State doesn't like to be disturbed in the peaceful possession of its omnipotence. . . . . A fine reason, certainly! But this situation from which the State wishes to protect itself is the common right. Railway servants and miners are combined, and do you think the companies are too well pleased with the spirit that these innovations delelop in their staffs? Haven't they often complained? Wouldn't they like to get rid of the unions? But they have to put up with them because it's the law. When the law was made it was well known that its effect would be to lighten the serfdom of the wage-earner, to diminish the power of the master, that in protecting the one it exposed the other, and that these effects would be accompanied by others; the shifting of power, the weakening of authority. But the law was passed nevertheless, because it contained a principle of social justice before which all considerations of a contingent order must bow. Why should the State, then, seek to protect itself from obligations which its own judges impose upon all other persons? It sets a bad example by trying to disembarrass itself of a law when it does not suit it."

These words apply with equal force to the condition of English State employés. The State must either set itself the task of initiating reforms and keeping its employés abreast of the changing conditions of life, or it must give to those employés the full right of combination to enable them to fulfil this necessary and useful function themselves. At present, it does not do the first of these two things, and places difficulties and dangers in the way of the second; and the reason that a greater outcry has not resulted is, that only among the lower grades of postal employés, who are so meagrely paid as to feel the pinch of the changes around them, whose salaries leave no margin for adjustment, and who are brought directly into contact with the labour needs and problems of the day, have unions grown up and the restrictive regulations been enforced. But the sphere of those affected is growing, the public conscience is slowly awaking, and ere long the model employer, it is to be hoped, will be a useful, if tardy, model in this respect also.

Any summary, however brief, of the telegraph clerks' case, would lack an essential to completeness, did it not contain some references to the vexed question of overtime. Probably no portion of the trouble has been more subject to misrepresentation than this. When telegraph clerks have complained about compulsory overtime, it has been assumed that they took exception to the performance of any extra work that the exigencies of the service under abnormal conditions demanded. This is far from being the case. Telegraph clerks, despite the discouragements to zeal, are as much interested in the efficiency of their service, are animated by as much public spirit as many more generously paid bodies. They have never objected to giving extra attendance under extraordinary conditions; what they take exception to is quite another matter. They object to the chronic overtime exacted from them by the ordinary constant pressure, which they contend should be met by an increase of staff, and bring to them the concomitant benefits of promotion which are incident on service development. And when this continual overtime to meet ordinary and calculable pressure is made compulsory, and failure to readily undertake it is attributed to lack of zeal for the service, what wonder if not only their rights appear to them to be invaded, but their pride is wounded. A recently issued official statement of the London clerks puts the complaint forcibly and briefly. "It must be remembered," it says, "that the hours of duty vary throughout the whole of the day and night, so that any increase adds considerably to the discomforts of a telegraphist's life. The papers given to a clerk upon entry into the service state nothing regarding extra attendance, excepting occasional Sunday duty. The present Postmaster-General issued a circular stating overtime to be compulsory, and threatened the staff with severe punishment should any refusal take place. Sir A. Rollit, at the conference with Mr. Hanbury and the Duke of Norfolk, declared the Post Office had no legal right to enforce the demand, but the State could compel obedience under pain of dismissal. The subject is one that eminently calls for settlement, otherwise the eight hours' duty is extended indefinitely, and telegraphists are in the position of having no privileges and no rights. No difficulty has ever been experienced by the Department in obtaining volunteers for the ordinary fluctuations incident to the telegraph service, but, owing to the persistent undermanning of the staff, overtime is chronic throughout the summer months. The secretary of the Post Office indicated before the Tweedmouth Committee his willingness to sacrifice efficiency for economy, and it being cheaper to compel the present clerks to perform overtime during the busy season than to increase the staff, the Postmaster-General's recent decision is regarded as bearing in the same direction."

We have now traversed the principal points in dispute between the telegraph clerks and the postal administration, and although the whole matter is far from exhausted, enough has been related to show the roots of the difficulties and bring out the necessity for a change of policy in treating the discontent existing in the minor establishment. The policy of forcible repression has failed as utterly as it deserved to fail, and discontent is greater and more articulate than before that policy was initiated. Such a policy is deeply ingrained in the fibre of permanent officialdom, is consistent with its traditions, and will doubtless exhaust the energies of many well-intentioned Postmasters-General ere it is finally eradicated. A recent letter from the Secretary of the Post Office is a glaring example of the uncompromising and unconciliatory attitude assumed.

Throughout the sittings of the Tweedmouth Committee, as, indeed, always, telegraph clerks had been reminded of the many advantages they enjoy over and above those vouchsafed to the ordinary human worker, and not least among these trumpeted advantages was the permanence of their employment. They worked for an employer who never died, who never failed, and was, in many other ways, a model. They had heard it so often that, against their reason, they had begun to believe it. It may be that the soreness caused by the failure to get sympathetic, or even just consideration, of their grievances, had, to some extent, been healed by contemplation of these advantages. But while the wound was still smarting the balm was rudely torn away. In a letter to a correspondent, dated August 31st, 1897, Sir S. Walpole said:—"Telegraphists are not employed in the service of the Post Office under any kind of contract. The Civil Service certificate, which they obtain as a necessary condition of their employment, contains no contract, and gives no right to the holder; it merely certifies that he is qualified for a particular situation, such as that of telegraphist. The position is, therefore, simply this:—The telegraphist is employed during the pleasure of the Postmaster-General, and if he does not do what is required of him the pleasure may cease, and with it the employment."

Of course, we all know that the Postmaster-General, as steward of Her Majesty, exercises the right of dismissal at pleasure, that no formal signed contract is entered into by the Post Office to provide or maintain employment for a telegraphist. But we also know that the power theoretically possessed cannot be arbitrarily exercised in the way more than hinted at in the passage quoted, and that there is an implied contract which is not, and cannot be, altogether disregarded. It is impossible to dissociate telegraphists from the rest of the Civil Service in this matter of fixity of tenure. So the deliverance did not cause a panic of terror. It has been introduced here merely as an illustration of the useless irritation and possible exasperation likely to be caused by the unsympathetic policy of the Department.

The time has arrived when the Postal Department should depart from the time-worn traditions of an effete economic era, and approach the question of the discontent of its employés in the spirit of the best employers of the day, to whom it professes the *rôle* of model. The spirit should be a conciliatory one, and the end not the useless endeavour to stifle discontent, but a sincere desire to do justice, and remove the causes of disaffection. If telegraph clerks are listened to in this spirit, their demands will be found not to be exorbitant, nor will their attitude be found unreasonable, and the way will be short to the realisation of a contented, willing, efficient service.

THE USE OF ELECTRIC MOTORS IN PAPER MAKING.

It is extremely interesting to notice that nearly every special industry presents to the electrical engineer a series of problems new to him, and peculiar to itself. For this reason, possibly, it comes about that electrical engineers are continually engaged in what is real research work of a very high order. The application of electrical power to industries hitherto depending upon steam, is not merely a simple change from one system to another, but involves the most ingenious adaptations. Electric power has to stand upon its own merits, and be accepted or rejected according as it is or is not well fitted for the purpose in view.

Speaking broadly, the fewer intermediaries between the point at which power is generated and that at which it is utilised, the better for economy so far as power is concerned. And, therefore, if an electric motor is thrust between the prime mover and its work, it must show good cause for its presence. The energy necessarily lost in it must be compensated by a greater saving of energy somewhere else, or by some economy in time or labour sufficient to be worth the while.

Whenever electric motors have proved important adjuncts in any manufacturing process, it has usually been for one or more of the three following reasons, each of them definite and sufficient:—First, they may have enabled a cheap prime mover to be substituted for a costly one. Second, they may have materially reduced the energy lost between the prime mover and the point at which its power must be applied. Third, through their characteristic facility of application they may have been able to replace manual labour at some point in the process of manufacture. Beyond this, electricity may have an intrinsic value as the source of new processes, but electric power, as such, takes in these no part.

In the paper making industry, manufacturers have been, on the whole, somewhat slow to adopt electrical power instead of steam, doubtless feeling a little nervous as to the result, being only too well aware of the disturbance which so radical a change would make in their capital, yet a little reflection will show that paper making is one of the most suitable industries in which this motive power should be employed. This industry is invariably situated within free access to water power, and though until comparatively recently one would have hesitated to advise driving from water power either directly or indirectly, any machinery requiring uniform speed at varying load. It is possible to use water wheel governors which are able to help the speed with an exactness quite comparable to the governing of a good engine.

At a meeting of the American Paper Pulp Association, held in New York on February 17th last, Dr Louis Bell made a strong plea for electricity in paper making, and gave some extremely interesting and cogent arguments drawn from his knowledge of particular cases in order to show that if electric motors were introduced, they would be attended not only with great convenience, but would effect a very tempting reduction in the cost of working a factory. Of course, cheap motive power from water-falls is an essential; this once gained, the electric power can generally be developed at a lower cost than the local cost of steam power. A great point in favour of using electric motors in paper making is the fact that power is often used continuously throughout the whole 24 hours, and this is a condition which is very favourable for electric working. Dr. Bell realises that each case has to be considered upon its merit, but he says that the few instances in which transmitted power is actually at use in paper mills, all the reports received seemed to indicate the success that was to be anticipated.

At the same meeting at New York a very interesting description of an electrical plant, yielding good results, was given by Mr. Charles F. Scott. We think the following extract from this paper may prove suggestive to those of our readers who may be in touch with paper manufacturers.

The factory is a large one, and is located at Cumberland Mills, about 4 miles from Portland, M.E. Some 5 miles below the mill on the Presumpscot River is a water-power, having some 10 feet fall with about 1,500 available horse-power. At this point machinery is placed for the transmission of power back to the mill.

At the station are two 300-H.P. two-phase Westinghouse generators, each driven by two 48-inch Victor vertical wheels. The generators are operated in multiple and supply a current at 1,100 volts to four 200-H.P. step-up transformers, which deliver the current at 8,000 volts to a three-phase line of bare copper wire by which the power is carried 4 miles to the mill, where the pressure is reduced by four 133-H.P. step-down transformers to 400 volts for supplying two-phase motors, and an additional transformer of the same size supplies current for lighting. There are seven two-phase Westinghouse induction motors; four 50-H.P. motors and a 75 H.P. motor are used to drive pumps and other machinery, and each of two 100-H.P. motors is direct coupled to a 100 H.P. direct current generator which furnishes current at 110 volts for electrolytic purposes. (Rotaries could now be used for this work, but were not available when the plant was installed.)

This plant drives machinery in the pulp mill and is also used for an electrolytic process, and arrangements have been made so that the entire mill lighting can be taken from this system if desired, but ordinarily this lighting work is done by a separate plant.

In addition to the transmission plant just described, there is also a direct current transmission of about 250 horse-power from Mather generators, at 500 volts, from a station aobut a mile up the stream from the mill. This plant was installed prior to the polyphase plant, and drives various machinery in the sorting house, and has been used for operating the calenders. All the motors in both systems are belted to short lines of shafting or directly to their work. The standard speeds of belted motors has been found satisfactory. In certain parts of the mill the motors are necessarily exposed to chlorine gas, so that the least possible exposure of brass work or other metal subject to corrosion by these fumes is desirable. The polyphase motors installed about two years ago have not suffered interruption or damage from this source, and seem to be entirely satisfactory for the work. It is a serious question whether direct current motors with their exposed commutators, brush-holders, &c., would stand this service satisfactorily. In some parts of the mill there is considerable dampness, but this has not been so excessive as to require waterproof or inclosed motors. The pulp pumps are sometimes jammed and absolutely stopped by pieces of wood which get into the pump cylinders. This necessarily stops the motor, and the characteristics of the alternating current motors are extremely valuable, as this sudden stoppage does no harm whatever. A direct current motor if placed in circuit and treated in the same way will be seriously injured, if not burnt out, by the very heavy current and the violent sparking which would occur.

Tests at this plant show an efficacy of 75 to 77 per cent., that, is for every 100 horse-power mechanical output of the turbines the motors deliver 76 or 77 horse-power to the machinery at the mill. The tests of the power consumed in the pulp mill, before its operation by steam was abandoned, and again after the electrical plant had been installed, show a marked and very gratifying saving in the amount of power used, resulting from the more direct application of the power to the machinery and the elimination of the dead load of long shafting bevelled gears and belts.

It has been found advantageous to divide the motors used into many small units, thereby securing independent control of the different classes of work as well as saving considerable power which would otherwise be lost in long shafting, cross belts, bevelled gears, &c. Induction motors appear to be better adapted for the work than synchronous motors, although the infrequent stoppage of such parts of the work as the electrolytic process, for example, would make the use of the latter permissible.

SCIENCE ABSTRACTS.

To ascertain what work has been done, and what papers have been published on any particular subject, has hitherto been, and is still, a matter of considerable difficulty and labour to investigators and inventors, and especially so to a scientific man who absolutely requires a knowledge of the previous work in preparation for his attack on some problem. The difficulty, moreover, is rapidly increasing with the number of investigators and authors. Papers are continually published discussing problems and modes of operation which are well known, and have been worked out many years before. Undoubtedly men will always be found ready to rush into print with accounts of their work, without examining closely whether it is new and interesting to other people. In some cases this may be due to vanity, in others to a desire for advertisement; some do not realise that a subject of absorbing interest to the author may be old and trite to others; but in an immense number of cases the cause is undoubtedly ignorance of work previously done. Councils of scientific societies, and editors of scientific periodicals, have continually to accept or reject contributions submitted to them, and often prefer printing matter, not strikingly original, to discouraging a new investigator. But all these papers, whether the work of students or skilled experimenters, crude speculations or exact calculations, have to be taken into account by subsequent writers. If it were possible to refer readily to an index for the published literature of any subject, many of these papers would never be published; or, if published, only in confirmation or criticism of previous writers. Some writers might then prefer the construction of analyses or reports of the previous work in their subjects, to attempts, sometimes ill-directed, at individual advance. So a reference to such an index might enable a teacher or editor to assist a writer to criticise his own work without discouragement. The economy effected in the time of advanced and original investigators in discovering and looking up previous work, and of the authors of monographs and text-books, would be invaluable to them.

The best method of dealing with the matter is not easy to decide; but a great number of experiments have been made, and some conclusions reached. The Royal Society publishes a catalogue of scientific papers, similar in general arrangement to the author's catalogue of a library. Each volume of this well-known work is a complete index of all scientific papers published during a certain period. It is edited with scrupulous care and exactness, and published in a style corresponding with the dignity of its source. But it has all the defects of its quality. It is always of necessity some years in arrear; its alphabetical arrangement makes it impossible to publish any part of the period before the rest, and there is no subject classification. In past years its pecuniary circumstances have caused great delay in the production of the several volumes, even after the close of their respective periods; but this point has been, and is being, greatly improved. But even if it could be kept up to date, the Royal Society's catalogue would not altogether meet people's requirements. While an author's index, or still better, a subject index, enables a writer to consult readily all the works bearing on his subject, a set of systematic abstracts saves the trouble of consulting many of them at all, by indicating their scope and mode of treatment. As an instance, the writer having occasion to look up some particular point, obtained from indexes and catalogues a list of about 40 papers whose titles indicated that they might bear on his subject. Of all these, only two dealt with the point at issue.

Abstracts might have saved consulting the other 38. It is, moreover, important that the references should be available very soon after publication of the paper. Where many men are at work simultaneously on the same subject, as is now the case with cathode rays, the Zeeman effect, and electro-magnetic oscillations, the abstracts of newly published work should be in the subscriber's hands immediately after publication.

These conditions, however, are not easily met. Promptness in abstraction and publication involves risk of misrepresentation, and it is impossible to read some of the abstracts of papers published without perceiving that the abstractors have their idiosyncracies. It certainly appears that abstracts should at first be provisional, and afterwards be submitted to revision by the original authors, if the collection is to be a permanent work of reference. The impersonal and colourless statements of the Royal Society's catalogue free its editors from the sort of anxiety which we think an editor of abstracts must occasionally share with him of a newspaper.

For a long time past the journals of several societies have regularly contained abstracts of papers bearing on their own branches. The Institution of Civil Engineers have edited theirs with great care and completeness, and the Electrical Engineers have followed them closely. Since January, 1895, the Physical Society has done the work for physics and the allied branches of chemistry, and we believe the latter society has strained its resources, both of men and money, in carrying out their admirable and useful plan. The technical press has done its share, we ourselves having regularly read a large number of papers, choosing for abstraction those that seem to offer most general interest.

In all this disorganised work, however, power is wasted, many papers being dealt with by several persons, while others are overlooked altogether, and we note with great pleasure the appearance of a regular publication devoted entirely to this kind of work, and organised apparently with care and completeness. The Institution of Electrical Engineers and the Physical Society have joined their resources to publish *Science Abstracts* under the editorship of Mr. James Swinburne and Mr. W. R. Cooper, and give brief but fairly complete *précis* of all the important articles on physics and electrical engineering appearing in a long list of 53 periodical publications, which, we are informed, is being enlarged daily. This list does not at present bear on its face its principles of construction. We find *Comptes Rendus* but not *Philosophical Transactions*, the *Journal of the Society of Arts*, but not of the corresponding French body, la Société d'Encouragement pour l'Industrie Nationale; but omissions are to be expected at this stage. The first number appeared in January, and the second in February of this year; and the two numbers contain notices of 230 papers and articles. The second number has been sent to us with an invitation to criticism, but for this we have no desire. We only wish to express our cordial goodwill for the new child as well as for its parents and its nurses, and we hope it may have a long and vigorous life. Its degree of success must depend on the number of subscribers it secures, since without outside support it must be a considerable tax on the resources of the parent societies. We venture to express a hope that many of our readers, who do not receive copies as being members of one of the two societies, may think fit to subscribe to it. It is not unlikely, we think, that the establishment of a University for London may ultimately greatly assist ventures of this sort by the informal, though very real, connection they acquire with a large organisation, and a united body of scientific men. With success might come a further development that would be of great value. The publication from time to time of monographs summarising the progress along different paths, somewhat on the lines of encyclopædic articles, or British Association Committee reports, would be of great value; and *Science Abstracts* may not only find the bricks, but actively assist to build the Temple of Science.

Lighting Licensed Buildings.—At the meeting of the Middlesex County Council on Thursday last week, it was resolved that in future all buildings licensed by the Council for stage plays, or music and dancing, and where lighted by electricity, should have an auxiliary system of lighting.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. THOMPSON & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

6,773. "Improvements in and relating to street lanterns for the reception of incandescent electric lamps." J. E. STEWART. Dated March 21st.

6,831. "Improvements in electric miners' lamps." W. O. WOOD. Dated March 21st. (*Complete.*)

6,834. "Improvements in safety devices for use in connection with high tension electric conductors." C. H. WORDINGHAM. Dated March 21st.

6,865. "Improvements in electric conductors and in appliances for making connections with same." J. D. F. ANDREWS. Dated March 21st.

6,902. "Improved details of electric tramways and railways." W. ALDRED and G. CARR. Dated March 22nd.

6,903. "Improvements in electric plug connectors." A. E. TANNER and G. W. LOWCOCK. Dated March 22nd.

6,954. "Improved holders for electric lamps." J. C. VAUGHAN. Dated March 22nd.

6,989. "Improvements in electrical measuring instruments." E. WESTON. Dated March 22nd. (*Complete.*)

6,990. "Improvements in electrical measuring instruments." E. WESTON. Dated March 22nd. (*Complete.*)

6,991. "Improvements in electrical measuring instruments." E. WESTON. Dated March 22nd. (*Complete.*)

6,992. "Improvements in electrometers." E. WESTON. Dated March 22nd. (*Complete.*)

7,061. "Improvements in telephone transmitters." G. F. PAYNE. Dated March 22nd. (*Complete.*)

7,027. "Improvements in dynamo-electric generators and motors." S. G. BROWN. Dated March 23rd.

7,057. "Improvements relating to plug switches and plug connections for the control and distribution of electric currents." H. F. PROCTOR and J. R. BLAIKIE. Dated March 23rd.

7,058. "An improved method of preventing the corrosion of electric battery connections." W. R. UNDERHILL and P. W. NORTHEY. Dated March 23rd.

7,129. "An improved means for generating electrical energy." T. HOLMES, A. HOLMES, and G. S. HOLMES. Dated March 24th.

7,150. "An electric locomotive." H. L. TODD and E. HARKER. Dated March 24th.

7,164. "Improvement in apparatus for electric signalling and adjuncts thereto." F. B. HERZOG. Dated March 24th.

7,170. "Improvements in, or in the construction of, electrical storage batteries." F. F. YEATMAN and W. DONOVAN. Dated March 24th.

7,199. "Improved wall socket and plug for electrical fittings." L. G. TATE. Dated March 24th.

7,236. "An apparatus, or improved manner of means, for determining or ascertaining the velocity of air currents in coal mines and other situations by novel electrical and other means." J. THOMPSON. Dated March 25th.

7,283. "Improvements in miners' lamps and apparatus for electrically lighting the same." S. HARRISON. Dated March 25th.

7,296. "Differential electric transformation apparatus." H. H. LEIGH. (Paul Lemaire, France.) Dated March 25th.

7,305. "Improvements in, and relating to, electrical accumulators." J. TABRAR and W. WALLER. Dated March 25th.

7,306. "Improvements in electrical bull's eye lanterns." J. TABRAR and W. WALLER. Dated March 25th.

7,310. "A divided cylinder dynamo." W. DOHERTY. Dated March 26th.

7,333. "Improvements in the construction of plates for electrical accumulators or storage batteries." E. MERIAN. Dated March 26th.

7,367. "Improvements in, or relating to, electric indicators or annunciators." A. J. BOULT. (The Antwerp Telephone and Electrical Works, Belgium.) Dated March 26th. (*Complete.*)

7,384. "System of lever drawbridges with overhead conductors for electric railways." A. CLEMENTS. (Union Electricitats Gesellschaft, Germany.) Dated March 26th. (*Complete.*)

CORRECTION.

6,633. For "an electrical charge conductor" on p. 464, April 1st, read "electrical charge *indicator*."

THE

ELECTRICAL REVIEW.

VOL. XLII. APRIL 15, 1898. No. 1,064.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 968 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

DEGREES IN ENGINEERING.

NEXT Tuesday is set down for the second reading of the London University Commission Bill. This is a matter to be looked to most earnestly by all who desire the welfare and progress of engineering education in London. Young men who are studying the scientific part of engineering in London, are, and have for many years been, at a serious disadvantage as compared with their fellows who may be studying in other centres of the British Islands, since by the antiquated red-tapism that has dominated the Burlington House establishment, they are cut off from the chance of taking a degree in engineering. Young engineers studying in Glasgow, Manchester, Liverpool, Belfast, Cork, Dublin, Leeds, Dundee, or even in Cambridge, find a University degree open to them as the culminating point of their theoretical studies. The student who goes to University College, London, to work in the Engineering Laboratory created by Prof. Kennedy, or to the Central College of the City Guilds' Institute, to say nothing of the engineering courses at King's College, or at any of the newer Technical Institutes, finds no such chance open to him. The institution some 10 years ago of the Engineering Tripos at Cambridge has in reality been a severe blow to the London schools of engineering, cut off as they are from all organic connection with the doctrinaire examining board which possesses the title of University of London.

The Senate of the University seems to think the holding of a schoolboy matriculation in Jamaica of more importance than the creation of an engineering tripos for London students in London. It is, in fact, a London University only in name, being, like the Civil Service Commission, only an examining body, debarred by its very charter from teaching, or from appointing professors, or organising laboratory instruction, and may not spend on this object one sixpence out of the thousands of pounds it receives as fees from candidates. *It simply pays those fees into the Treasury to relieve general taxation!*

Of its many defects, a most withering indictment was recently framed by Mr. H. G. Wells, the well-known *litterateur*, in the pages of the *Outlook*. He points out how the University library is practically inaccessible, owing to the room, intended as a reading room (where the books are locked up), being nearly always used for examinations—sometimes even for practical anatomy examinations, giving "a thin, permanent odour, of dogfish and rabbits about the place." Fancy dissection in a library! Mr. Wells's narrative is, however, too graphic to be dismissed quite so briefly:—

"Whiles this grey and grimy University is dusty, desolate, and empty; whiles great crowds of bearded young fellows, callow men, priests from Stoneyhurst and Dissenting ministers, medical students, Hindoos, Board School teachers, the cheap hacks of private schools, careless school girls, too careless to pass! and careful school-mistresses, too careful!

and a most variegated tag-rag and bob-tail of specially hired commissionaires and graduates in unaccustomed gowns, also (gowns and graduates) specially hired. . . . . Outside lurk the hirelings of such notorious crammers as Mr. Briggs and Mr. Kerin, and so forth, armed with handbills and such like bait to thrust into the candidate's hand."

The engineering candidate is, indeed, conspicuous by his absence, just as the crammer's candidate, who has been "prepared" by correspondence for the pass degree in Arts, is conspicuous by his superabundance. The only thing that the University can offer him—supposing he has passed marticulation and intermediate examinations—is a Bachelor of Science degree, to acquire which he must select to be examined in any three out of the following subjects:—pure mathematics, mixed mathematics, experimental physics, chemistry, botany, zoology, animal physiology, geology, and mental and moral philosophy. Engineering is simply ignored.

For some 15 years there has been on foot an agitation for reforming the University. Some have favoured the creation of a second separate teaching University in London. Others have worked to reform the existing University by trying to reconstruct it. The former plan has commended itself to some who bore little love for the old examining Board, and would have gladly seen it superseded by a modern rival. The latter plan has been advocated by those who had a real attachment to the University with all its defects, and did not wish to see it strangled by a younger rival. Two parties have grown up—those who desire to see the University reformed and reconstituted, and those who wish to see its examinations left severely alone, and the work of teaching and organising education in London given to a new University. It is 11 years since a charter for a second University was applied for and refused in Parliament. Since that epoch two Royal Commissions have sat upon the question, and both—one by a mere majority, the second unanimously—condemned the notion of two Universities, and recommended the reconstitution of the existing University.

The Bill now before Parliament is a Bill to create a statutory commission under Lord Davey, armed with Parliamentary powers to carry out in general the recommendations of the second Royal Commission, modified, however, by certain safeguards which have been introduced as a part of a compromise arranged by Sir John Lubbock and his friends to meet opposition. The scheme will create a new representative Senate, with boards of studies, an academic council, and a board to look after the interests of external students. It is supported not only by the present Senate and by the Convocation of Graduates, but by all the educational authorities in London affected by the Bill, the great Colleges, the Royal Colleges of Physicians and Surgeons, the Polytechnic Council, the Technical Education Board of the County Council, and by the Medical Schools. It is supported also by engineers generally, who desire to see the quality of instruction in engineering raised to a higher level. It is supported by the Royal Society, as tending to raise the value of degrees in science, and of science teaching in general; and it is supported by many old graduates because it will tend to rescue the University, and particularly the B.A. degree, from the lowered reputation into which it has fallen in consequence of the vast growth, during the past 20 years, of organised cramming. The rage for competitive examinations which overtook England a generation ago has left many deep traces in educational life. It has effectually crippled the University of London, and retarded the progress of higher education in London. Under its *régime*, the examination, which ought to have been a mere incident at the close of a well-directed course of studies, has become the end and aim of all. The natural course of training is perverted to the sole purpose of examination passing. Education is warped, and teachers hampered by the trammels of the system. Cram dominates all. The Bill now before Parliament, is but the first step toward the undoing of this disastrous state of things. Every engineer, civil, mechanical, or electrical, who desires to see the University of London reorganised on modern lines, should urge his Parliamentary representative to support the Bill.

Forms of Electrical Treatment.

THE memorable crusade against electrical quackery some five years ago was immediately followed by a distinct weakening of faith in electrical treatment. Unfortunately, the public memory is a short one, and we have for some time noticed a distinct revival at the hands of quacks of that blessed word, electricity. The claims of the Electrical Hospital of Notting Hill have not, until recently, met with the consideration which they merited; indeed, had it not been for the advertising medium of a coroner and his jury, there is a large probability that the institution would have long remained comparatively unknown. It is unnecessary to detail the whole of the circumstances that have brought the Electrical Hospital into prominence, but the main facts are that John Salter, an artist, aged 71 years, was found dead at 51, Peel Street, Kensington. The Coroner said "the deceased had received treatment at a so-called 'hospital,' by electricity, but the people being unqualified could not give a certificate, and an inquest was necessary. In some cases electricity was beneficial, but in others might aggravate a disease and accelerate death, which made it a serious matter. He could not understand why people did not go to a proper hospital for treatment." The evidence revealed the hospital to be an institution at Notting Hill, presided over by Prof. D'Odiardi, a name familiar to our readers, who claims to be a medical electrician. Certainly to our own knowledge this gentleman has been associated with medical electricity for a considerable period. It was admitted that the "Professor" had no medical qualifications, but that proved no obstacle to his treatment of consumption, throat affection, blindness, short sight, internal diseases, tumors, influenza, and special treatment of the voice for public speakers, &c. In the case of the poor aged artist he was treated at the Electrical Hospital for muscular paralysis and numbness of the legs, but according to medical testimony the cause of death was syncope. Apart from the very strong rider of the jury and the caution of the Coroner, the evidence given was remarkable, most striking developments in electro-medical treatment having apparently arisen at Notting Hill. Our readers are fairly well acquainted with the action of X rays, yet "Prof." D'Odiardi is actually using them in the treatment of disease. The Coroner, in his examination of one of the nurses, asked the following questions:—

Nurses are sent out with apparatus, including that for the X rays?—Yes, for diseases; they did not take photographs.

With what object?—We use them for the eyesight.

For people who are blind?—Yes.

The "Professor," in his testimony, said he "found X rays useful in many diseases which caused a weak circulation. It re-animated capillary circulation." The cutaneous troubles arising from the application of X rays have been commented upon in these columns, and it has been necessary to devise methods to obviate them, yet here is an unqualified man pretending to treat blindness and other complaints by X rays, with probably disastrous results. The warning of the Coroner came not a moment too soon, and in the interests of genuine electrical treatment it is to be hoped that Mr. D'Odiardi will bear it in mind.

THE COST OF GENERATION AND DISTRIBUTION OF ELECTRICAL ENERGY.

(*Concluded from page* 471.)

MR. HAMMOND next deals with the efficiency of the generating plant and refers to the great improvement which has taken place in the last ten years or so, and to the important place which must be assigned to this efficiency as a factor in the low cost problem. The conditions usually specified by him for steam consumption tests are quoted, and his method of fixing the amount of the penalty for any failure on the part of the contractor to obtain the guaranteed results is explained. We notice, however, that no mention is made of a bonus to the contractor if the latter succeeds in getting better results than those guaranteed, and we would suggest that the offer of a bonus, similar in amount to the penalty, would be a further inducement to manufacturers to strive after better results even than those which have already been obtained. A table of steam consumptions at full load for various plants tested under the conditions already specified is given, and reference is made to guarantees which have been given for plant now under construction; but we should have been glad to see figures quoted for the steam consumption at three-quarters and half load, as these latter are generally even more important for central station work than the full load figures.

In this connection, we would say a few words for governing by automatic expansion. We are well aware that Capt. Sankey and Mr. Morcom, in their valuable papers on the Willans and Belliss engines, have quoted tests showing that with these engines, although there may be some advantage in governing by expansion valve if the I.H.P. is taken as the basis of comparison, this apparent advantage disappears and the balance turns in favour of throttle valve governing when the more rational basis of consumption per B.H.P. or E.H.P. is taken. These results appear to be due to the considerably increased friction of the engine when governing by expansion, and this particular loss certainly has not the same relative importance in slow speed engines such as are used sometimes for large powers; whilst the facilities afforded by the expansion valve for arranging that the lowest consumption of steam shall occur at some other load than full load are much to its advantage, owing to the fact that the plant load factor during running hours can hardly be expected to average more than 75 per cent. We remember seeing a guarantee for a slow-speed compound-condensing engine, which seemed to us a good example of what is required for central station work. The normal full load output of this engine was 450 B.H.P., but it had to work up to 550 B.H.P. as an emergency load, and the guaranteed steam consumptions per brake horse-power and per hour were as follows:—20·9 lbs. at 150 B.H.P.; 18·2 lbs. at 250 B.H.P.; 17·6 lbs. at 350 B.H.P.; 18·1 lbs. at 450 B.H.P.; and 19·8 lbs. at 550 B.H.P. It will be seen that, making allowance for the dynamo efficiency, it is possible with such an engine to get an electrical horse-power at the dynamo terminals at any load between half and full load for a consumption which does not vary more than about 5 per cent.; that the best results are obtained at about three-quarter load, and that a 20 per cent. overload can be obtained with about 10 per cent. higher consumption.

In speaking of the efficiency of the generating plant, nothing is said about boiler efficiency, and yet there is no doubt that a great part of the difference between the coal consumption that can be obtained on a full load test, and that which is obtained in practice as the average of the year, must be debited to losses in the steam raising plant. We believe that it is the practice in many stations to measure the feed water by meter, and to enter up the amount registered every 24 hours, and we hope that in the discussion some information may be given as to the efficiency of the boiler plant under different conditions of working as regards output and load factor. Various schemes for thermal storage have also been brought forward in the last few years, and we should like to know if any hopeful results have been obtained from them in practice, and whether there are any prospects of a better all-the-year-round efficiency of the steam raising plant being obtained in the near future.

When speaking of efficiency of distribution, Mr. Hammond refers to the various views held by engineers as to the headings under which the difference between units generated and units sold should be entered, and states that in some cases the units used for magnetising or lost in the batteries are entered under the heading of units used on the works. That there should be any engineers who so misunderstand the meaning of the Board of Trade form is certainly surprising, as the magnetising units can no more be counted as units generated than those which are spent in overcoming the resistance of the armature or in iron and frictional losses in the machine; whilst the units lost in the battery should undoubtedly be debited against distribution. We agree with Mr. Hammond that the form used by the Westminster and St. James's Companies is an improvement on that prescribed by the Board of Trade, but we think that another column under the heading of units utilised might be added with advantage, so that the units used at the generating station for lighting might be separated from those used for power purposes, such as driving feed or circulating pumps, mechanical stoker gear, or elevators for raising coal. We suggest this addition because such electric motors take the place of engines that would otherwise be drawing steam from the boilers; and, since the units utilised in this manner are again used for generating purposes, they cannot strictly be included in the net units generated.

In the table given in the paper showing the ratio of the units used in distribution and unaccounted for to the total number generated, there will be found a striking difference between the losses in the low pressure and high pressure systems, and also between the maximum and minimum values of these ratios for the various undertakings working on the same system. For example, for the year 1896, we find that the average value of this ratio for low pressure systems is 8·3 per cent., the maximum 14·09 per cent. (at Southampton in the sixth year of working), and the minimum 2·32 per cent. (at Hull in the fourth year of working); whilst for high pressure systems the average value of this ratio is 26·2 per cent., the maximum 39·88 per cent. (Newcastle District Company in its sixth year), and the minimum 9·38 per cent. (Reading in the second year of working).

With regard to the question discussed in the paper, as to whether the coal bill can be considered in any way a reliable test of the all-round efficiency of an undertaking, it is evident, as is pointed out by Mr. Hammond, that neither the actual cost of fuel nor the weight of fuel consumed per unit sold can be taken as a satisfactory basis of comparison, owing to the great differences in the average price paid by the several undertakings, which ranges from less than 5s. to more than 20s. per ton, and to the difference of quality which naturally increases the weight consumed when cheap fuels are used. We must add that we do not think that a comparison of the thermal units in the fuel consumed per electrical unit will help us much, as with different qualities of fuel, the actual evaporation which can be obtained under the most favourable circumstances is not proportional to the calorific values of the fuels as determined in the laboratory; indeed, this difference may be very considerable, as the percentage of the total thermal units that can be utilised for evaporation may, with some fuels, be more than 50 per cent. greater than it is with others. To get a really fair basis of comparison, it would be necessary to make a series of tests of actual evaporation with the various qualities of fuel burnt in boilers of the several types used in central stations, so as to get for each fuel a figure which would represent the best possible evaporation that could be obtained with it.

It must, however, be remembered that the engineer in charge of a station often finds plant already in service, and that the task which is set before him is to get the best possible efficiency out of the existing plant, and that he has not the chance, perhaps, of replacing it by other plant which could give a better result. Under these conditions, the all-round efficiency which is interesting to him is expressed by the ratio of the average weight of fuel actually consumed per unit sold, to the weight of fuel necessary to produce a unit at the dynamo terminals under the best possible test conditions. We would, therefore, recommend that in all works tests should be made on full load with the usual quality of fuel, and that the engineer should always keep the results of this test before him as the ideal consumption to which he has to approach as nearly as possible; and that tests of 24 or 48 hours' duration should be made under working conditions at various seasons of the year, so that the relative importance of the several losses under different conditions may be ascertained.

In the course of his paper Mr. Hammond quotes the ideal costs given by Mr. Crompton in 1894, and also tabulates some ideal costs made up by taking the best results for each item obtained by any works and combining all these records in one undertaking, and then discusses the probabilities of any works obtaining equally good results. He also concludes his paper with a prophecy as to the cost per unit at Leeds when the output reaches 5,000,000 units, and we propose to conclude these notes by a few remarks on this subject. As regards fuel consumption, it is unfortunate that Mr. Hammond has not given us any information as to the weight of fuel now used per unit at Leeds, nor as to its calorific value, so that it is difficult to get a correct appreciation of what is really represented by his prophecy, that the cost of fuel will be $\frac{1}{5}$th of a penny per unit when the output has reached 5,000,000 units. He speaks, however, in another part of his paper of its being possible to compare the coal results of works drawing from the same coal fields, such as Bradford and Leeds; and if we are to assume that the price at Leeds is about the same as that given for Bradford, the prophetic figure means a consumption of under 5 lbs. of fuel per unit sold. This appears to us to be a figure which will be difficult of attainment, unless the increased output is accompanied by a considerable improvement in the load factor; as, if this latter remains at about its present value, at which the units sold are only 70 per cent. of those generated, the consumption of fuel per unit generated will be under $3\frac{1}{2}$ lbs.

An examination of the tables of fuel consumption shows us that we are still a long way off Mr. Crompton's ideal of $2\frac{1}{2}$ lbs. of Welsh coal, the best result quoted in them being the 5·8 lbs. at Oxford, followed by the St. James's, Westminster, and Kensington companies, with 6·4, 6·5 and 6·6 lbs. respectively. Improvements may be made by the use of larger and more efficient generating units; but so long as the load factor remains at its present low figure, we believe that the stand-by losses in the boilers and condensation in pipes will prove the great obstacle to a reduction even to 4 lbs. of Welsh coal, no matter how much the actual output may be increased. Wages will also be diminished by the use of larger units, and automatic machinery for handling coal, but so far the best result is that obtained at Edinburgh of ·20d., or double the ideal cost proposed by Mr. Crompton; and the same difficulty will be experienced in reducing this item if the maximum demand on the works increases in anything like proportion to the output.

With regard to repairs and maintenance, we have already pointed out that the figures for stations which have been running for several years do not show such a great reduction in this item; and, although there is every reason to believe that Mr. Crompton's figure of ·35d. per unit may be improved on, we think that Mr. Hammond underestimates this item when he puts it at only one-tenth of a penny in his prophetic costs. The last items, rent, rates, taxes and management are beyond the control of the engineer, and depend to a great extent on local circumstances. We have already shown that with some of the most important undertakings, the tendency is towards a very slight decrease, and in some cases even there is an increase in this item; and there is nothing in the statistics published by Mr. Hammond to lead us to expect very material reductions. On the contrary, we know that there is a tendency on the part of local rating authorities to increase the assessment on electric light stations far more rapidly than is pleasing to the proprietors; that rents are proportionately higher if a station has to extend beyond its original boundaries and acquire leases of neighbouring property; that engineers and managers all hope for a substantial increase of salary with the growing importance of the undertaking; that the expenses of reading meters and collecting payments increase and that directors' fees have to be provided as the undertaking becomes more successful. We are, therefore, of opinion that Mr. Hammond's prophecy is somewhat too optimistic, but at the same time, we sincerely hope that he may be able in a few years to show us that we are wrong, and we can assure him that we shall only be too glad when the time comes that we can congratulate him on the fulfilment of his prophecy.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Concluded from page* 438.)

It will be seen that these motors show high power factors and efficiencies even at low loads, while the drop of speed is very little. These good points are well brought out in fig. 17, which gives a test of a 2-H.P. Kolben motor designed to

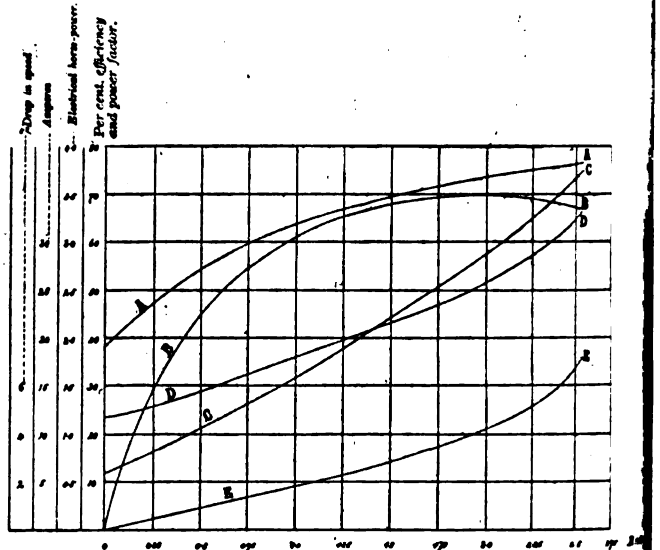

Fig. 17.

run at 1,500 revolutions per minute on a 50 ~ 110-volt circuit. The curve marked A A shows the percentage power-factor, B B the percentage efficiency, C C the electrical horse-power absorbed, D D the amperes at 110 volts, while curve E E gives the percentage drop in speed. The general

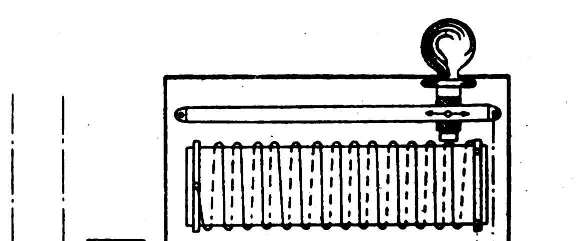

Fig. 18.

design of the Kolben motors is not very different to that of Messrs. Brown. The semi-rectangular stator holes used have already been noticed. Another point is that the stator core discs are magnetically separated from the case in which they are built in. This not only minimises leakage from the stator, thus tending to improve the power factor and the starting, but at the same time better ventilation is secured. The stator is drum wound with flat coils, as in fig. 8. The smaller motors up to 8 H.P. are all built with plain rotors, and are started up in a manner similar to that shown in fig. 12A, a non-inductive resistance being used instead of the condenser. The particular arrangement used is well shown in fig. 18, from which it will be noticed that the resistance is capable of being adjusted for different starting currents and torques. Motors above this size have a three-phase winding on the rotor, whose ends are connected to slip-rings as before described. They start up with the same device used in conjunction with a non-inductive rotor resistance. Fig. 19 gives the winding scheme of such a rotor for a 20-H.P. six-pole Kolben motor for a low tension circuit at 50 ~.

Mr. Kolben has recently been carrying out experiments with large motors, using mica condensers, which latter seem to promise the best results, not only for high pressure motors, but also for those working at low voltages. In this last case the pressure is transformed up by a small converter for the starting phase, as shown in fig. 20. A non-inductive resistance is, of course, used in the rotor. After the motor has run up, the transformer is switched off. In order to make

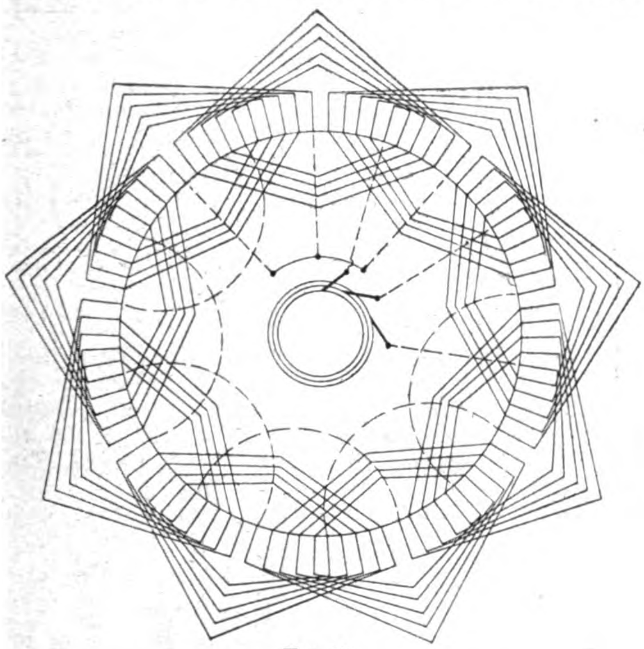

Fig. 19.

the motor perfectly safe under normal working conditions, the starting winding of the motor is made in two sections,

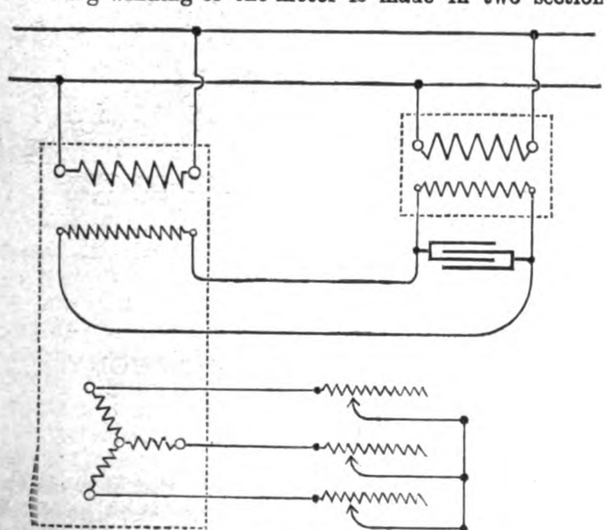

Fig. 20.

which are cross-connected after the motor has started and the transformer switched out, for otherwise the field of the working winding would produce a constant high pressure in the starting coils. A transformer would not be necessary in those

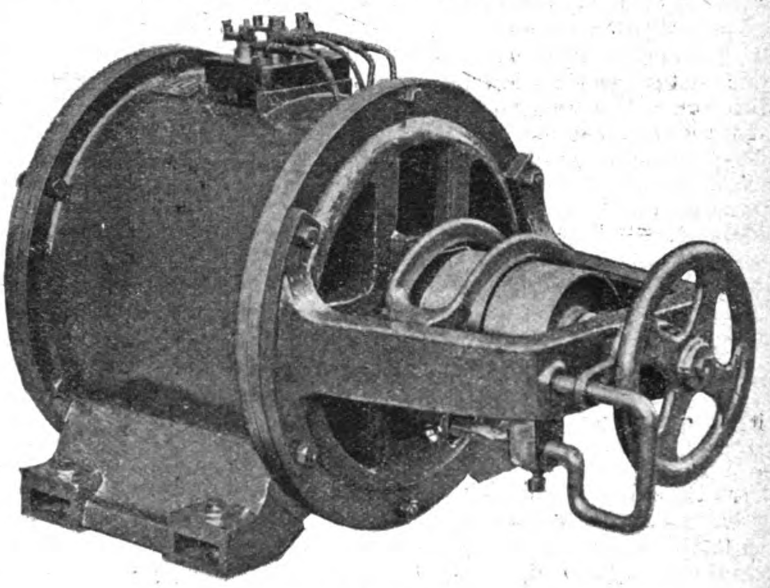

Fig. 21.

places where the high pressure circuit is directly available. This method of starting should prove very effective for high frequency motors.

It is worthy of note that in the case of high pressure Brown motors, the high pressure is reduced for the starting windings and condenser, while for the Kolben motors the high pressure is directly utilised; and if not available directly, is obtained by transforming up. This is, of course, because in the first case the condenser is of the liquid type, acting by electrolytic polarisation, and cannot stand a high voltage; whereas, in the second case, it is an ordinary condenser, and becomes smaller for the same effect as the voltage is raised.*

Fig. 21 shows one of Messrs. Kolben's 6-H.P. motors with fast and loose pulley.

(*D*) *The Allgemeine Elektricitäts Gesellschaft.*—This firm (the pioneers of multiphase working in Germany) have of late years been turning their attention to single-phase induction motors, and with very satisfactory results. Their design is on the same lines as those of the other firms mentioned above, but with a special starting winding used in conjunction with a non-inductive resistance. Mr. Stöttner, the manager of the company's London branch, recently showed the present writer two motors satisfactorily working at 100 ~ under trying conditions—one was comparatively small, the second, of nominal 6 H.P., driving a circular saw of large size. They were both working wonderfully smoothly, the latter hardly emitting any noise when fully loaded. This is rather a common characteristic of high frequency motors of any size, being most prominent at starting. The motor in question started up very quietly indeed, taking about 60 seconds to reach full speed on the loose pulley.

The single-phase motors noticed above are the only ones that have had a lengthy practical trial and been uniformly successful. Many others have been designed by various people, and with various schemes, to make them self-starting, but it remains to be seen whether they are capable of being successfully operated in any but toy sizes.

Single-phase motors of the induction type have undoubtedly solved the problem of power distribution from ordinary lighting circuits. It is true that all those in successful operation are of Continental make, but then the demand for power is much greater there than here, and must be satisfactorily met. And, as a rule, the alternate current generators on the Continent are much better able to take care of a combined light and power load than is the case in England, where the generators generally regulate extremely badly on any load containing self-induction. That this poor regulation on inductive loads is unnecessary, is shown by the case of Frank-

* Current through condenser = $2 \pi n \kappa \times$ the secondary E.M.F. of transformer. Hence if the condenser is to give a particular current, both a high frequency and high E.M.F. tend to reduce its size.

furt, where the lighting is quite as good as in any English town, despite the fact that motors of all sizes (including several of 70 H.P.) are running on the lighting circuits. The present writer was assured by the engineer of the Frankfurt station that the motor load gave him no trouble whatever; in the case of the large motors, he, of course, knew when they were coming on.

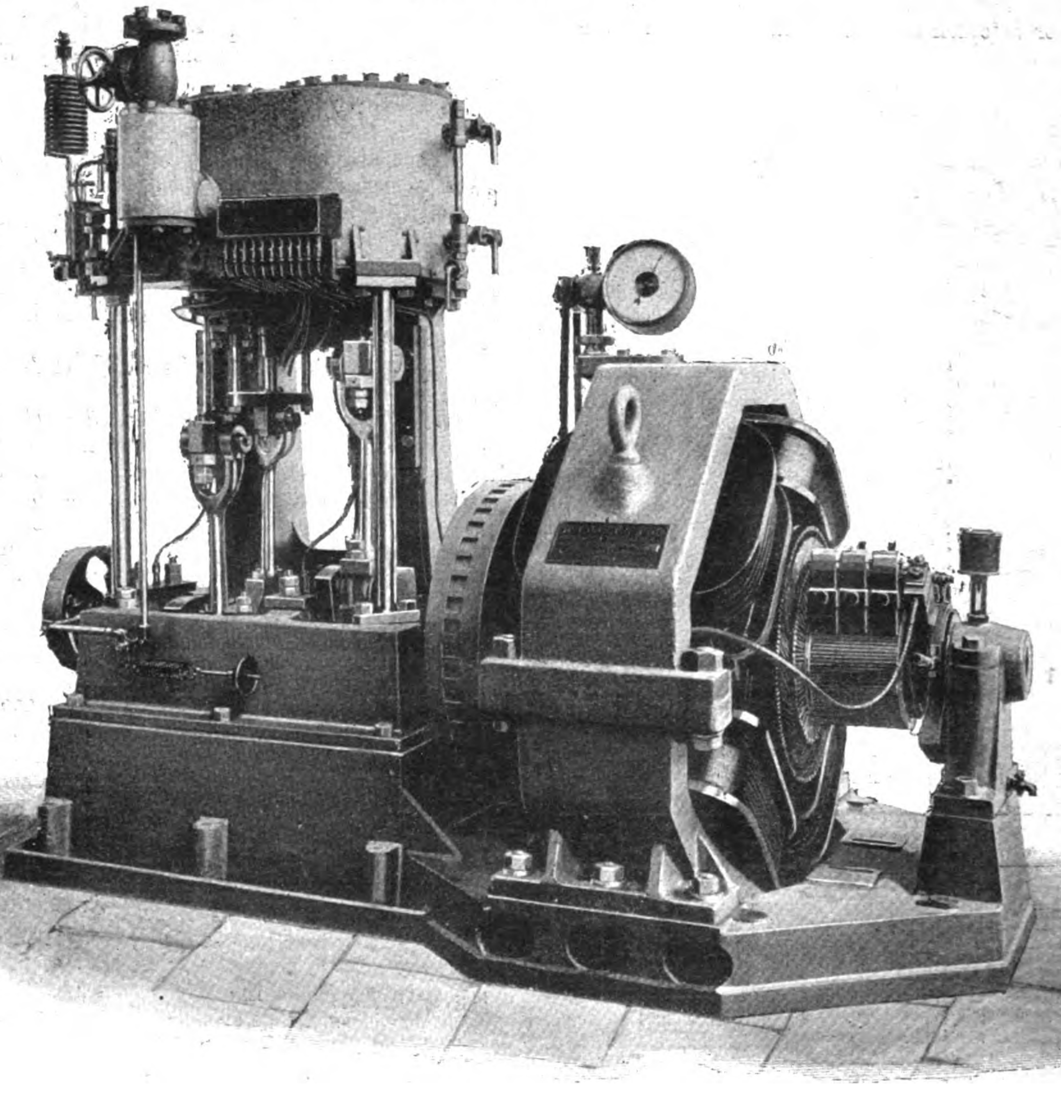
In conclusion, considering the excellent performance of motors such as those of Brown, Kolben, &c., it is rather difficult to understand why the common complaint heard so often here, that "alternate current motors cannot be run on lighting circuits" should exist. It is to be hoped that this complaint will disappear, as the present tendency to adopt reasonable frequencies becomes more general in this country.

THE LIGHTING OF WARSHIPS.

With the object of reducing the external magnetic leakage of dynamos, which was liable to affect the ship's compasses, the British Admiralty some years since made trial of a two-pole ironclad type of dynamo. This form of machine was, however, found heavy, and in order to reduce the weight, while at the same time keeping the magnetic leakage at a minimum, the Admiralty have now adopted a multi-polar machine. The illustration represents an 80-volt 600-ampere set running at a speed of 300 revolutions per minute, lately supplied by Messrs. W. H. Allen, Son & Co. for H.M.S. *Amphitrite*. The armature is of the series-wound drum type, the current being collected by two sets of brushes placed 90° apart. The core is secured to the shaft by means of a cast-iron spider, open at each end to allow free access of air, so as to ventilate the armature thoroughly. The commutator is built up of hard drawn copper sectors, and is insulated everywhere with mica. The magnets are of high permeability, cast-steel throughout, and consist of a yoke ring with four radiating poles projecting inwards bolted to it. The yoke ring is in two halves, the division being on the horizontal diameter, allowing of the easy removal of the armature without in any way disturbing the magnetic coils. The latter are wound on formers so that they may be readily removed or replaced.

The engine, which, with its dynamo, is mounted on a combination base plate, is of the compound vertical double-acting type, having cylinders $7\frac{1}{2}$ inches and 15 inches diameter × 9 inches stroke. The working parts are of steel, having a tensile strength of 30 tons with an elongation of 27 per cent. in 2 inches. The bearings have white metal linings. The engine is constructed for a working steam pressure of 300 lbs. per square inch. The steam consumption upon trial at the makers' works was 26 lbs. per electrical horse-power per hour, with a steam pressure of 200 lbs. per square inch, when exhausting into the atmosphere. The maximum temperature rise of the machine after a six hours' full load trial did not exceed 65° F. above the temperature of the surrounding atmosphere. The difference in weight between the four-pole set and an ironclad two-pole of the same output is over $2\frac{1}{2}$ tons.

Sets of a similar type, but for 400 amperes, have been supplied by this firm to H.M. ss. *Hermes*, *Highflyer*, and *Hyacinth*.



INDUCTANCE IN TELEPHONY.

By W. MOON.

The effects of inductance together with that of electrostatic capacity are more important in telephony than that of resistance. The effect of a distributed capacity, as it occurs in practical telephony, it is impossible to calculate. But if the inductance of the circuit be dealt with apart from capacity, the figures are not difficult, and I propose in the present paper to deal only with such inductance effects.

The inductance of a piece of apparatus can be readily measured by Maxwell's method, fig. 1.

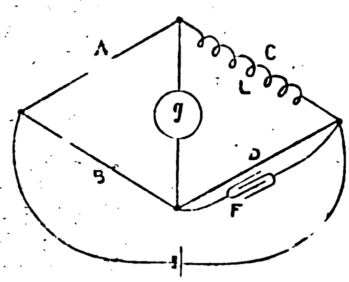


Fig. 1.

The bridge should first be balanced for steady currents, without any capacity in the condenser, and a deflection read "q_L" on closing or opening the battery circuit. The apparatus in arm "C" should then be replaced by an inductionless resistance which should be adjusted to obtain a fresh balance for steady currents, and a reading "q_r" taken on opening the battery circuit from the discharge of the condenser.

If then the arms "A" and "B" are equal

$$L = \frac{q_L}{q_r} F D^2.$$

There is no advantage to be gained by using unequal values in the arms "A" and "B" of the bridge.

The mutual induction of a piece of apparatus can be best measured by comparing the discharge "q_m" from the secondary circuit, when the primary circuit is closed, with the discharge from a condenser "q_r" through the galvanometer, as shown in fig. 2, where the secondary coil is first joined to the

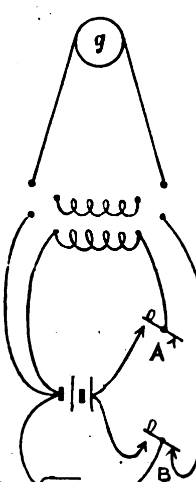

Fig. 2.

galvanometer, and the discharge taken with key "A," and a discharge afterwards taken from the condenser through the galvanometer with key "B."

$$\therefore q_m = M \frac{E}{R S} \text{ and } q_r = E F$$

$$\therefore M = \frac{q_m}{q_r} F R S,$$

where "M" is the mutual induction, "R" the resistance of the primary circuit, "S" that of the secondary circuit, and "F" the capacity of the condenser.

In double wound coils, the inductance of each coil and the mutual induction between them is the same. And as mutual induction can be more readily measured than self-induction, it is sometimes convenient to specially double wind particular coils in order to obtain their self-induction from the measured mutual induction.

When the battery is reversed between each measurement of mutual or self-induction, the deflection on closing the battery circuit is always greater than that of breaking it. This is due to the effects of the residual magnetism. The two deflections being proportional to "$c\,a$" and "$c\,b$," and the residual magnetism effect to "$b\,a$" on the magnetisation curve, fig. 3.

Thus the inductance for alternating currents should be measured by reversing the battery while the balance is

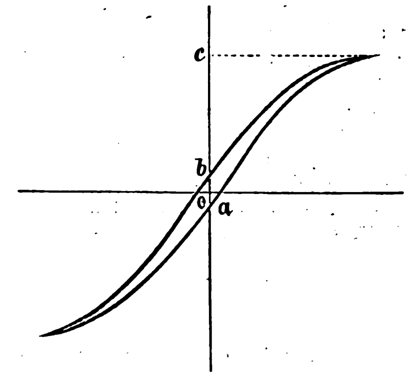

Fig. 3.

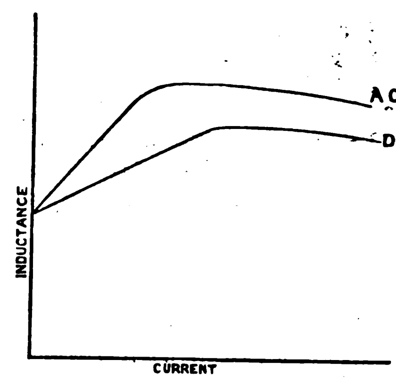
steady, or half the sum of the deflections, on opening the battery circuit, reversing the battery, and closing it again, may be taken. While for single current working the inductance should be measured by the deflections produced on opening the battery circuit only.

In all apparatus containing iron the inductance varies with the strength of the current used; and the inductance is greater with alternating currents than direct ones. But



A C, alternating current; D C, direct current.

Fig. 4.

with very small currents the difference between the inductance with alternating and direct currents is very small, as shown in fig. 4.

And the inductance for telephonic currents is not much less than that of the smallest currents by which the inductance can be measured.

The following list of inductances is for telephonic currents:—

	Henrys
Nonpolarised relay 1,000$^{\omega}$	4 9
Polarised indicator relay 1,000$^{\omega}$	8 6
Telephone galvanometer 4,000$^{\omega}$	52·
Magneto bell 1,000$^{\omega}$	15·
Switchboard telephone 75$^{\omega}$	·01
Bell telephone 150$^{\omega}$	·1
Self-restoring indicator local cicuit 250$^{\omega}$	·64
Self-restoring indicator line circuit 1,000$^{\omega}$	17 5
Telephone transformer 2[illegible]0$^{\omega}$ each coil	3 5
Triple wound transformer primary 150$^{\omega}$	5·
Triple wound transformer each secondary 1[illegible]0$^{\omega}$ ...	·73
Telephone induction coil 250$^{\omega}$	1 75
Telephone induction coil, mutual induction	·016

When the resistance and inductance of a circuit are known the impedance can be calculated from the formula

$$I_m = \sqrt{R^2 + p^2 L^2}$$

where $p^2 = (2 \pi n)^2$ and n is the number of pulsations per second.

In telephony "p" depends on the pitch of the voice, and hence there is a maximum and minimum impedance. For male voices n ranges between 90 and 140 pulsations per second. And for female voices between 280 and 560 per second. So that for male voices $p^2 = 320,000$ to $770,000$, and for female voices $p^2 = 3,095,000$ to $12,400,000$. And a maximum and minimum value of p^2 might be taken as 12×10^6 and 3×10^5 and a mean value as 2×10^6. Or for rough calculations p^2 may be taken as 10^6.

A number of telephonic apparatus are used as a shunt across others; the joint impedance of two such circuits is :—

$$I_m = \sqrt{\frac{(R^2 + p^2 L^2)(R_1^2 + p^2 L_1^2)}{(R + R_1)^2 + p^2 (L + L_1)^2}}$$

where "R" and "L" are the resistance and inductance of one circuit, and "R_1" and "L_1" that of the other.

The proportion of the whole current passing through "R_1"

$$= \frac{\sqrt{R^2 + p^2 L^2}}{\sqrt{R^2 + p^2 L^2} + \sqrt{R_1^2 + p^2 L_1^2}}.$$

Thus, an induction coil and Bell receiver in series having a resistance of 300^ω and an inductance of ·25 henrys would have an impedance on short-circuit of

$$\sqrt{300^2 + 3 \times 10^5 \times \cdot25^2} \text{ to } \sqrt{300^2 + 12 \times 10^6 \times \cdot25^2}$$
$$= 330 \text{ to } 916 \text{ ohms,}$$

and an indicator relay of $1,000^\omega$ and 10 henrys would give 5,560 to 34,700 ohms.

So that if the indicator relay is used as a shunt across the telephone and induction coil it would take

$$\frac{330}{330 + 5,560} \text{ to } \frac{916}{916 + 34,700}$$

$=$ ·056 to ·0257 of the whole current.

A magnetic bell of resistance $1,000^\omega$ and inductance 15 henrys, if used as a shunt across a circuit would give an impedance of 8,250 to 52,000 to speech, but only an impedance of $1,800^\omega$ to the current from a magneto generator when p^2 is taken as 10^4.

The principle of mutual induction enters largely into telephony as apart from the use of transformers for joining a single line on to a looped one, or their use in superimposed circuits; the telephonic induction coil acts as a transformer and may be regarded as such. Also the iron cores and iron sheathing of coils act as secondary circuits of small resistance and inductance.

The current "x" in the primary circuit and that "y" in the secondary circuit of a transformer are given by the formula

$$x = \frac{E_m}{\sqrt{(R + \nu S)^2 + p^2 (L - \nu N)^2}} \qquad (1)$$

$$y = \frac{E_m \sqrt{\lambda}}{\sqrt{(S + \lambda R)^2 + p^2 (N - \lambda L)^2}} \qquad (2)$$

where "R" and "L" are the resistance and inductance of the primary circuit, "S" and "N" that of the secondary circuit, "E_m" is the mean electromotive force apart from phase.

$$\lambda = \frac{p^2 M^2}{R^2 + p^2 L^2} \text{ and } \nu = \frac{p^2 M^2}{S^2 + p^2 N^2}$$

where "M" is the mutual induction.

The current, "I," without the transformer in circuit would be

$$I = \frac{E_m}{\sqrt{(R_1 + S_1)^2 + p^2 (L_1 + N_1)^2}} \qquad (3)$$

where the quantities in the denominator are reduced by the values of the resistances and inductances of the transformer.

To get the best effect from a transformer, obviously the primary and secondary coils should be so wound that its primary resistance and inductance should be in proportion to the resistance and inductance of the primary circuit, and its secondary resistance and inductance in proportion to the resistance and inductance of the secondary circuit.

(*To be continued.*)

THE WELSBACH INCANDESCENT ELECTRIC LAMP.

By A. M. Gibson.

So much has been written and spoken in a vague way about the latest invention of Dr. Auer von Welsbach, and such great expectations have been raised as to its ultimate commercial value, that all who are interested in the progress of electric lighting will welcome some definite information on the subject.

The following particulars are taken from the complete specification which has been "laid open for public inspection" by the Hungarian Patent Office at Buda-Pesth.

Two kinds of glow-bodies for use in incandescent electric lamps, with several different methods of producing the same, are described in this patent application. The first is a fine filament of osmium of a peculiar form. As is well known, osmium is one of the platinum group of metals. It usually occurs as a compound known as osmiridium, in flat, irregular grains, and sometimes in hexagonal prisms. In the separation of the iridium and osmium, the latter is generally found to contain ruthenium. It is easy to obtain the pure osmium from the ruthenium compound on account of the affinity osmium has for oxygen, the tetroxide, $Os\,O_4$, forming readily. The tetroxide is, however, extremely volatile, and the fumes given off in reducing by volatilisation to obtain the pure metal, are very poisonous. The vapour of tetroxide destroys sight if the eyes are exposed to it.

The second filament is one formed from thoria, the earth metal oxide so largely employed in the preparation of incandescent gas mantles.

Dr. Carl Auer von Welsbach has worked out several different methods of obtaining his osmium and thoria filaments, but so far these methods are merely laboratory processes. Lamps, it is true, have been made which, according to Dr. Auer, give very remarkable results, and he claims that a phenomenal high efficiency lamp, with a long, economical life, can be produced. While the inventor has not made any public statements as to the exact efficiency and life of his filaments, it is reported, on no particular authority, that the wattage per candle is under 2, and even as low as 1·5.

Osmium has never been fused. At the point at which iridium melts the osmium goes off in fumes, which take fire in the air and form tetroxide of osmium. It is possible to obtain it in an amorphous powder which can be converted into crystals. Osmium is the heaviest of metals, its specific gravity, determined from the crystalline form, being 22·477. It is undoubtedly the most refractory metal.

Dr. Auer claims that osmium does not volatilise at the highest temperature obtainable if confined in a vacuum or if surrounded by reducing gases. He does not make clear what he means by surrounding with reducing gases, but presumably it is that the gases are present in such a way as to exclude oxygen, because it is undoubted that with free access of oxygen osmium does vaporise.

One of the methods Dr. Auer employs to obtain his osmium filament he describes as follows:—A platimum wire of 0·02 mm. diameter is fixed in a vacuum surrounded by vapour of hydro-carbon, greatly diluted with water into which small quantities of tetroxide of osmium are blown from time to time. The wire is glowed in this atmosphere, and a thin layer of metallic osmium is deposited thereon. The deposit must be effected slowly, and from the context of the description of the process it inferentially appears that a number of very thin layers must be obtained. There is difficulty in obtaining perfectly uniform deposits, anything like warts, or nodules, of course, would affect the regular resistance of the filaments. The fragility of the coated wire as it comes from the flashing apparatus is admitted to be great, because the layers contain some oxide, *i.e.*, the layers are not in this stage pure metallic osmium. Therefore the glowing is continued until the very thin platinum core is volatilised, and the osmium coating becomes homogenous, and you have a tube of pure osmium. This is described as being elastic and nearly the colour of platinum.

The coating may also be effected by drawing the fine platinum wire through a solution of a sulphide or tetrahydroxide of osmium, and then glowed in a vacuum. If this method is employed, the operation must be repeated at least 100 times, in order to obtain the requisite thinness of layers.

There is also an electrolytic method mentioned, but there is no description of the method of preparing the electrolyte of osmium, or of the current required in this operation. It is, however, stated that the glowing of the wire must be carried out as in the other methods after the electrolysis is concluded. This part of the specification is exceedingly vague; but before a German or an American patent is obtained, fuller explanations of the electrolytic method will doubtless have to be supplied.

Vegetable or animal fibres can also be employed as the foundation for the osmium coating. A liquid pulp is made by mixing the finely triturated osmium oxide with sugar, or organic cementing material and water, and the impregnated thread of fibre, after drying, is brought into the required shape for the lamp, and slightly glowed in a reducing atmosphere. From this it appears that the osmium particles secure conduction. A carbon skeleton, carrying osmium unconsolidated, is thus obtained. It can be fixed in the lamp bulb, which is filled with reducing gases, and the glowing proceeds slowly, steam being also admitted to the bulb. The intensity of the current is gradually increased, until a very high temperature is reached. To secure uniformity of resistance, the filament so produced is normalised by flashing in a vapour of tetroxide of osmium and hydro-carbon.

Nitro-cellulose may also be saturated or mixed with pulverised pure osmium—the amorphous form, of course—or sulphide of osmium, or tetrahydroxide, and the mixture is then formed into threads by squirting, or otherwise, denitrated, and heated in the same manner as the fibres.

Instead of cellulose or fibres, a soft, slightly twisted cotton thread may be impregnated in a thin pulp of finely divided osmium sulphide and water, mixed with a cementing medium, as, for instance, sugar. The thread is dryed, and then carbonised in a reducing gas, such as illuminating coal gas.

Dr. Auer's method of obtaining his thoria filament is interesting. He states a fact which is not generally known, but which is quite true. A platinum wire brought to a white heat by an intense current, or other means, melts. A very thin platinum wire held in the hottest zone of a Bunsen gas flame will melt; but if the wire is coated with a firmly adhering cover of thoria, it will not melt at any measurable temperature. This is due to the fact that a great part of the heat energy, coming in contact with the absolutely fireproof material covering the wire (for instance, in the Bunsen flame) is converted into light radiating energy, or light emissiveness. This is as equally true of electric energy as with the gas flame. The intense power of the cover to emit light and heat withdraws energy from the metallic conductor.

Gradually raising the energy in intenseness, a dazzling white spot of light will occur at a place in the filament, and spread slowly (sometimes quickly) over the whole length. About this time a minute ball will be seen by the close observer to spring from the thread. This phenomena is caused by the volatilisation of the thin platinum core under the intense heat obtained by increasing the current tension. There is now left a tube of thoria, which will withstand still higher current tension, and the brilliancy of the light emission increases correspondingly. The curious part is, that at a current tension which fuses, or destroys any other substance, there is very little heat radiated by the brilliantly incandescing thoria filament. Continuing the increase of current tension, a point is reached at which the thoria tube bursts with a slight explosion. The thickness of the thoria cover need be but some tenths of a millimetre. A mere film will answer, in which case the colours of the rainbow will, at one stage of the experiment, appear.

It is evident, although not so stated in the specification, that the thoria covering must be dense, and in no wise porous. To obtain such a covering is exceedingly difficult.

Dr. Auer states vaguely that he uses "a preparation of thorium, which gives back an oxide when being glowed." A nitrate or a selenate of thorium will do this. The process described in the specification of forming the cover, doubtless, will answer in the laboratory, but in manufacture upon a commercial scale it must inevitably prove impracticable. The thin platinum wire 0·02 of a millimetre in diameter, approximating to the tenuity of the split cocoon silk filament, is drawn through elastic cheeks, which are moistened with the solution of thorium. After each drawing the wire is glowed. The drawing through the moistened cheeks, and the glowing, must be repeated at least 50 times. To reach perfection by this method the solution employed to moisten the cheeks through which the wire is drawn, must be very dilute, and the drawing and glowing must be repeated several hundred times. A wire of a compound of platinum and osmium answers better than pure platinum, because more infusible. A compound wire of platinum osmium, ruthenium and rhodium or iridium, answers better than platinum.

It is to be noted that in practice the platinum core is not volatilised. The experiment above described is merely to illustrate the enormous heat resistance of pure thoria.

Although not expressly stated in the specification, it is evident that the best results can only be obtained with the filaments of Dr. Auer by the employment of alternating currents.

The cost of producing either the osmium or the thoria by the processes described must be considerable. Platinum wire costs in proportion to the tenuity to which it is drawn. Ordinarily pure platinum costs, say, 50s. to 55s. an ounce. To draw down to 0·02 of a millimetre adds enormously to the price, for workmen can only be engaged in the operation a few hours on account of the strain upon their eyesight, to say nothing of the other difficulties encountered in the drawing. Then the repeating the process of coating and glowing several hundred times, no matter what mechanical devices are used, means great expense. It is true many filaments are obtained from 1,000 metres in length, but incandescent electric lamps are produced by the million.

There is one noticeable feature of Dr. Auer's specification, and that is the omission in the descriptive part to allude to the electrolytic way of producing on a platinum core, or any other conducting core, a dense, firmly adhering thoria coating or covering. It is well known to a limited number of experts, who have experimented with thoria, that such a coating or covering can be obtained by electrolysis. This coating can be deposited on platinum in any desired thinness from an electrolyte properly prepared, and readily and comparatively cheaply. Dr. Auer mentions the electrolytic way of securing his osmium coating, but for some reason he does not mention in the body of his specification the electrolytic method of obtaining a thoria coating; nevertheless, in his claims he very adroitly covers, indirectly, in the Hungarian patent, the electrolytic process of coating with thoria. Why this indirection?

Because the electrolytic way is not patentable!

Neither is it new that thoria is an absolutely fireproof material, nor is it novel that a very slight coating of thoria protects platinum from the effect of high temperature by transforming heat energy into light emission.

It is not new that platinum wire coated with an enamel-like covering of thoria has an enormously increased electrical resistance, and consequently a minimal volume of high tension current will give intense light emission.

CORRESPONDENCE.

Recent Smashes at Brighton.

In the ELECTRICAL REVIEW, appearing rather ominously on April 1st, there appears an alarming report to the effect that Mr. Crompton distinctly stated in his speech at the Institution last Thursday evening, that there have been recently a great many smashes at the Brighton Electricity Works, and implied that these were due to the use of high tension steam dynamos, and to the breaking of steam pipes. Perhaps it will be sufficient for me to say briefly:

1. There have been no smashes at Brighton recently, or during the last seven years.
2. High tension steam dynamos are not used at Brighton.
3. There are no steam pipes in proximity to high tension apparatus.
4. No breakage of steam pipes has occurred.

From the above, it is very evident that there is a "Nigger" somewhere in the reported speech of Mr. Crompton, who is the very last person to intentionally mislead his audience.

Arthur Wright.
Per L. A. D.

Weatherproof Wire.

As a subscriber for four years past to the Electrical Review, as well as the writer of the article on "Weatherproof Wire," noticed in your editorial of March 11th, I suppose I should answer the questions asked in the latter part of the editorial.

To the first one, "How it is possible to maintain such circuits in wet weather?"—the inquiry referring to the so-called weatherproof wire strung in the ordinary American fashion on glass insulators—I beg to reply that so long as the wires remain on the insulators and do not swing into contact with other conductors or semi-conductors, the maintenance of the circuit presents no difficulty. The insulation resistance of such a circuit is, of course, proportional to the number of insulators, and the resistance per insulator depends on the shape and size of the insulator, but is usually above 10 megohms during and after a soaking rain. With poles spaced 50 per mile, the total leakage from a line of any ordinary length is of no commercial consequence. If concentrated on one insulator it might become of consequence by breaking down the insulation, but the leakage is not concentrated and the glasses do not break down in practice.

The result of such construction is, in wet weather, a line of low total insulation but of sufficiently high insulation at each point of support; in other words, a line on which the leakage is uniformly distributed. This condition really tends to steady running with the large series arc dynamos. It is not theoretically perfect but practically it is good enough.

As a contrast to the satisfactory results obtained with "weatherproof" main line, there are in this country several stations where circuits have been installed to conform with theoretical requirements *as taught in the schools*. I know personally several underground systems which test excellently but break down whenever there is any unusual surge, such as will occur in service in spite of all customary care. The American practice of using series dynamos of high voltage for the supply of street arc lights has developed a few machines which are unsteady as well as some others which are remarkably free from that vice; and the combination of a surging machine built for 125 or 150 arcs with cables insulated by $\frac{1}{8}$th inch (or thereabouts) of good rubber has caused much sorrow to engineers responsible for the combination. Even an alternating circuit will surge occasionally in consequence of a local short-circuit, and cables which would pass Board of Trade inspection, puncture after a fashion that is very trying to a man accustomed to overhead lines. The overhead lines do not break down under such conditions.

In reply to your second question, as to whether superintendents are not tempted to let linemen take risks in bad weather, I regret to say that superintendents are much the same all the world over, and that such officers have at times risked their own lives, and other men's lives, to avoid shutting down of circuits, which is not a practice to be commended. Nevertheless, there have been few accidents on main lines under the conditions that you suggest; because main lines seldom get in trouble; because the risk is well known; and because in most cases a makeshift repair can be made in a manner not involving any personal risk. A hand line, usually a cotton sash-cord well soaked with tallow, is part of the equipment of a trouble-man; and an old hand does very neat work, when occasion requires, in the way of lassoing a "crossed" wire and bridling it up out of mischief. In a well regulated station the trouble-man has the right to order any circuit shut down, and is expected to avail himself of this right as often as he thinks advisable. The superintendent who sends men into danger has always been the exception, and I think is disappearing altogether from our ranks. The superintendent who goes in himself, will, I suppose, always remain with us. Some of us are not entirely ashamed of scars got in our younger days in just this way. Our comment is, when the subject is mentioned, that we are now old enough to know better; that it takes a youngster to be so foolish.

You will allow me, as a stranger to your columns, the privilege of explaining that I have been for years an advocate of underground wires, and that the circuits which I have placed underground have been free from breakdowns. And you will appreciate that when I speak of theory as taught in the schools, I mean the incomplete theory which has grown out of practice, and which, therefore, is usually a year or two (at least) behind practice. The theory of the line on which the leakage is uniformly distributed has been studied only by the telegraphists, and their results are only of indirect service to the electric light man. The schools, so far, condemn low total insulation on any circuit, and are just beginning to understand that a leaky circuit which will not break down has been for years the accepted standard of American overhead practice. American underground practice was influenced at first by the school theory, and the early failures were due to a belief that high measured insulation was all that was requisite. Within the last five years we have added a breakdown test to our insulation test in writing cable specifications, and some of us now buy cables without any test but a breakdown test. In this we are approximating our underground theory to our overhead practice. We have not any overhead theory; therefore there continue to be inquiries such as yours as to why such circuits as ours are possible. My article, on which you commented, was not so much a defence of our overhead construction as an invitation to some of our scholastic friends to consider the facts, and to evolve from them a theory which would be acceptable to both students and workers.

Alex. Dow.

The Alexandra Palace.—In our "Note" last week re the electrical features of the Alexandra Palace, we omitted to mention that the lighting and motor power work of the Palace and grounds is being carried out by Mr. Percy Huddleston, on behalf of the Acme Motor and Traction Company. It is running at a voltage of 250 volts, and the work is being done according to the Phoenix Fire Insurance rules. The motive power plant employed includes two 10-H.P. nom. Crossley gas engines and a 20-H.P. nom. compound Fowler undertype engine. The dynamos and motors were specially made at the Acme Motor Company's works at Brentford. The arc lamps used are by the British Blahnik Arc Light Company, Limited.

New Offices.—Messrs. Dick's Asbestos Company, of Canning Town, have taken offices at 51 and 52, Fenchurch Street, E.C.

Books Received.—"Alternate Currents in Practice," translated from the French of Loppé and Bouquet by F. J. Moffett, B.A. Whittaker & Co., 15s.

"Theory and Practice of Electrolytic Methods of Analysis," by Dr. Bernard Neumann, of Aachen, translated by J. B. C. Kershaw, F.I.C. Whittaker & Co., 10s. 6d.

"Radiography and the X Rays: In Practice and Theory," by S. R. Bottone. Whittaker & Co., 3s.

Catalogues.—We have received from Messrs. Gent and Company, of Leicester, a copy of their price list of pneumatic and electric bells, telephones, batteries, wires, &c., in which are given numerous illustrations of these classes of apparatus and sundry accessorial parts. From the same firm we have also received a pamphlet on electric lighting, giving general instructions for both town and private plants. The machinery and apparatus, and the many small fittings necessary for a lighting installation are illustrated and described in the pamphlet. Both lists contain prices.

Messrs. Dobson & Curtis Bros., Limited, of Suffolk Street, Dublin, send us a copy of the third edition of their catalogue of electric bells, telephones, &c. This firm, which has also a Birmingham branch, has carried out many large contracts in both England and Ireland, the most recent in England being for the Cycle Components Manufacturing Company, of Birmingham, the Dunlop Pneumatic Tyre Company, of Coventry, and Mr. Harvey Du Cros's private residence at Cornbury Park, Oxfordshire.

The Corporation of London v. City of London Electric Lighting Company.—At the Guildhall last week, before Alderman Sir J. T. Ritchie, an application was made concerning the City of London Electric Lighting Company, Limited, by the City Solicitor on behalf of the Corporation to ascertain the fees and reasonable expenses of an electrical inspector employed by the City, who claimed to the amount of £1,142 2s. 7d. under Section 47 of the Electric Lighting Orders Confirmation Act, 1890. Mr. Rose-Innes represented the Corporation of the City of London, and Mr. Roskill appeared for the company.

Mr. Rose-Innes opened the case, and pointed out that so far as the public was concerned it was essential that the electric light supplied should be kept up to a certain standard. The Electric Lighting Order of 1892 provided that an electrical inspector should be created by the Local Authority—in the present case the Corporation—and that all fees and reasonable expenses, unless agreed upon, should be ascertained by a court of summary jurisdiction, or, where appointed, the Board of Trade. What the Alderman had to decide was the amount to be paid by the electric light company to the Corporation for the inspection of meters. The electric inspector was to be "an impartial person standing in a judicial position," and the point which arose for determination was—apart from the salary which the Corporation saw fit to allow this gentleman—what were the fees and reasonable expenses in regard to the work which he had done.

Mr. Roskill said he did not dispute the scale of fees settled by the Board of Trade.

Mr. A. A. Voysey, electrical engineer to the Corporation, said in respect of his employment as electrical inspector, he received a salary from the Corporation. He was familiar with Sections 35 to 47, showing his duties. He found it necessary to have a testing office; this was near the Wool Exchange. The rent was originally £195 a year, but it was afterwards reduced to £170. This was paid by the late Commissioners of Sewers. His duty was to test meters with a view of deciding disputes between the lighting company and the consumer. The witness gave the various items of office expenses, which he said were paid by the Corporation. Mr. Voysey said he was aware that other public bodies had electrical inspectors—the London County Council, for instance.

Mr. Roskill: Are you aware that they never test meters, except on the premises of the consumer?

The Witness: Certainly not.

Mr. Roskill: Then you would be surprised to hear that that is so?

The Witness: Yes. I should not believe it.

Sir James Ritchie: In my neighbourhood the County Council have a beautiful building, and outside is written "County Council Testing Station."

Mr. Roskill said he was now informed that the County Council did have their own testing stations, but they made no charge on what was technically called the "undertaker."

Mr. Voysey, in answer to further questions, said he did other work besides testing in his office.

Mr. Roskill then at some length argued on the construction of the words "reasonable expenses." He contended that such expenses meant those incurred by the inspector travelling to test meters, and so forth, but how the Corporation could contend that the company were liable for any portion of the items put forward passed his understanding. The contention of Mr. Rose-Innes was this: That the Corporation appointed an inspector, supplied him with offices, instruments, and assistants at any cost they pleased, and then charged the electric lighting company for these things.

The Alderman: I have come to the conclusion that these are not reasonable expenses within the meaning of the Act, but I suppose one will have to hear evidence of what may be reasonable. I do not think that the electrical company are bound to provide offices and so on for these inspectors.

Mr. F. Bailey, chief engineer to the City of London Electric Lighting Company, having given evidence,

Sir James Ritchie said if a higher Court held that the items mentioned could be included amongst "reasonable expenses," in order to save the parties coming before him again, he would fix an amount. Inasmuch as the inspector had said that he gave about two-thirds of his time to testing he would reduce the amount to £937 11s. 8d. This was merely a formal matter to save the case being brought before him again to settle this question should a higher Court decide against him.

Mr. Roskill: Then the summons is dismissed subject to a special case.

Dissolution of Partnership.—Messrs. H. W. Ellis and E. W. T. Ward (Ellis & Ward, electrical engineers, Edmund Street, Birmingham) have dissolved partnership. Mr. Ellis will continue the business at the old address under the same name as formerly.

Electric Clocks.—The Swansea Public Library has deferred the question of electric clocks for the library for six months.

Electric Winding Plant.—On February 7th an electrical winding plant was inaugurated at the No. 2 south Great Eastern mine in the presence of an influential company from Gympie and Brisbane. The plant was manufactured and erected by Messrs. Trackson Bros., of Brisbane. A generator made by Laurence Scott & Co., supplies current to the motor, the shaft of which is coupled to the worm gear, which operates a gun-metal worm wheel keyed upon the shaft, which carries the winding drums. The distance between the generator in the engine room and the winding plant below is close upon 2,000 feet. The directors and manager expressed themselves perfectly satisfied at the way the plant handled various loads at different speeds. The design and erection of the plant has been supervised by Mr. P. Trackson, A.I.E.E.

First Meeting.—The first meeting of creditors in the bankruptcy of J. Fletcher and J. A. Hirst (Fletcher, Hirst & Co., electrical and mechanical engineers, of Chester and Derby) is to be held at the official receiver's office, Byrom Street, Manchester, on April 19th, at 3.30 o'clock. The public examination is fixed for April 29th, at 11 o'clock, in the Court House, Burnley.

Liquidation Notices.—At meetings of the British Electrozone Corporation, on February 8th and March 8th, resolutions were passed winding up voluntarily, and appointing Mr. A. E. Edwards, of Broad Street Avenue, E.C., liquidator.

A meeting of Messrs. J. C. Howell, Limited, is to be held at 6, Old Jewry, E.C., on May 16th, at 11 o'clock, to receive an account of the winding up operations from the liquidator, Mr. S. F. Lit.

Parliamentary Bills.—The *Daily Chronicle* had an article on Wednesday giving particulars of the progress of the numerous private Bills which are now before Parliament. There is an increase in the number and value of the Bills deposited for this session. There are 30 Bills relating to tramways, and the proposed capital involved in them is upwards of £1,800,000. Gas Bills ask £1,732,000, and electricity Bills come in with a modest million, and measures under the provisional order system account for a further sum of three millions odd, which the promoters seek to raise in respect of schemes for tramway, gas and water, electric lighting, &c. Five Bills to authorise the construction of new underground railways in the metropolis were deposited. The Charing Cross, Euston, and Hampstead Railway Bill has been read a third time in the Commons; another—the City and Brixton Bill has been reported by the Committee which considered it, and awaits third reading, and the Great Northern and City Railway, which is for an extension of the authorised undertaking, awaits second reading. Power to work by electricity is also being sought in the Metropolitan Railway Bill, and has been granted by the House of Commons Committee, to which the measure was referred. Notwithstanding the facilities given to promoters by the Light Railways Act, there are but three measures containing schemes for light railways and one for the acquisition of a railway which it is proposed to work as a light railway. Upwards of 80 provisional orders have been made by the Board of Trade under the Electric Lighting Acts, with a view to their submission to Parliament for confirmation; and there are besides four Bills relating to the supply of electrical energy seeking powers beyond the scope of the general Electric Lighting Acts. Some of the important questions so raised stand referred to the consideration of a Joint Committee of both Houses, which will sit again after Easter, and whose report will be awaited with interest.

Tasker & Sons, Limited, v. London & County Hotels Company, Limited.—This case came before the Coventry County Court on Tuesday last week. The plaintiffs, electric light engineers, of Andover, Coventry, and other places, sued the defendants for goods and work done in the construction of electric light apparatus at the King's Head Hotel, Coventry. It appeared that the plaintiffs supplied the hotel in May, 1897, with an installation of four electric arc lamps, using the city current. Defendants found the humming noise of the lamps annoyed their customers to such an extent that the lamps could not be used, and plaintiffs were asked to remove them. Mr. J. W. Manley, plaintiffs' local manager, stated that this humming noise was caused solely by the fact that the city current was an alternating one. His firm had on one or two occasions made alterations suggested by defendants' manager, with a view to mitigating the noise caused by two of the lamps being hung under a glass roof. The defendant company's case was that their manager was advised by an engineer of the plaintiff company to instal arc lamps, when nothing was said about the noise. They did not allege defective construction of the arc lamps, but the noise caused by them caused the customers to leave the hotel. His Honour gave judgment for £59 8s. 9d. for plaintiffs, striking out some extras for the fitting of speaking tubes which formed part of the claim.

Siemens & Halske.—Messrs. Siemens & Halske, of Berlin, are increasing their capital to £2,000,000. The Austrian and Hungarian branches of this firm are, it is reported, to be formed into a separate joint stock company.

Volenite.—Lord Lurgan, the chairman of the Fish Oil and Guano Company, had a good deal to say to his shareholders on the 5th inst. about volenite, to exploit which his company is bringing out another company. He said that tests of volenite had proved it equal to gutta-percha and superior to vulcanite. Its electrical resistance was really extraordinary. They were anticipating the results of some tests for the possibility of covering cables with this material, but a test of 10 to 12 months would be necessary, and they had seriously considered whether to wait that time before producing it, or whether they would find out to what other uses and purposes volenite might be applied. They decided to make the latter tests at once, and they very soon discovered that volenite was just as valuable for the purpose of steam boiler and steam engine packing as it was for electric cable work. Therefore, in view of its use for various purposes, they decided that they were justified in issuing volenite at once. It was now almost ready for registration. The prospectus was prepared. His lordship read reports made upon the material by Mr. Philip C. Pope, consulting electrical engineer, and Mr. J. W. Bevan, and opinions of other gentlemen. With regard to the manufacture of volenite it is intended to at present confine it to the United Kingdom. Favourable offers had been made for the sale of the patent for America, but it had not yet been decided whether to increase the capital and make it for all the world, or to sell the patent for different countries.

ELECTRIC LIGHTING NOTES.

Ayr.—Mr. Fuller's report as to extensions has been adopted by the Commissioners at a cost of £1,187.

Balmoral.—The daily papers say that the Queen has decided to light Balmoral Castle by electricity, and an enormous quantity of large iron pipes has already been delivered. These pipes are intended to convey water power from the Gelder, a stream running into the Dee at a point about 1½ miles from Balmoral, and the dynamos will be driven by water power.

Barnsley.—The Park and Lighting Committee report having held three meetings for the consideration of Mr. Miller's scheme for electrical supply to the borough. Mr. Miller attended and explained the scheme, and the further consideration stands adjourned until a special meeting on the 23rd inst.

Bath.—Mr. Hammond is to prepare a statement for the Council, showing the amount expended upon the electricity works together with the outstanding liabilities on the balances of contracts, and a special meeting is to be held to consider it. The Electric Construction Company has consented to give a guarantee in connection with the erection of arc lamps without having a preliminary test. Thirty out of 40 new lamps have been erected, and will be connected as soon as the circuit is completed.

Belfast.—The statement of accounts for the year ended December 31st, 1897, showed the electricity undertaking to be in a sound financial condition and progressing rapidly in the public estimation, and in view of the probability of having a considerable sum to pay this year by way of interest on the large capital expenditure connected with the new station which cannot be productive for some time, the balance carried forward from last year was ordered to be allocated for this purpose. The meters necessary on the introduction of Wright's system of charging for electric current on July 1st, are to be purchased, and also a fourth Lancashire boiler to complete the first section of the new station.

Blackpool.—The Corporation passed the following resolutions on 5th inst.:—"That subject to the confirmation of the Local Government Board to the requisite loan, the tenders of the firms undermentioned for extensions at the Corporation Electricity Works be accepted, viz.: Boiler and superheaters, Messrs. Babcock and Wilcox, Limited; condensers and storage tanks, Messrs. Cole Marchent & Morley; rectifiers, Messrs. S. Z. de Ferranti, Limited; boosters, Mr. Chas. J. Cowan; cables, British Insulated Wire Company; transformers, Messrs. Nalder & Hilton, Limited." "That the approved standard clauses issued by the Electrical Engineering Plant Manufacturers' Association, and the Municipal Electric Association, for the adoption among the general conditions of specifications for electrical engineering plant, be referred to the town clerk and borough electrical engineer for inclusion, if they think so fit, in any conditions of specification for electrical engineering plant issued by the Electric Lighting Committee."

Bournemouth.—The following tenders were sent in for supplying and fixing cables, conductors, lamps, columns, fittings, &c., for the lighting of the pier and Lower Pleasure Grounds:—

	£	s.	d.
Messrs. Johnson & Phillips	2,255	18	0
Brush Electric Engineering Company	1,740	0	0
Messrs. Fippard & Cooper	1,521	18	0
Mr. L. G. Tate	1,602	0	0
Messrs. Laing, Wharton & Down, Limited	1,707	0	0
Messrs Cash, Robinson & Co.	1,252	17	0
Bournemouth and District Electric Supply Company	1,415	0	0
British Insulated Wire Company, Limited	1,583	14	9
Mr. E. G. Bryant	1,458	6	0
Messrs. Crompton & Co., Limited	5,204	0	0

The surveyor recommended the tenders of Messrs. Cash, Robinson and Co., and the Bournemouth and District Electric Supply Company for consideration. The Council had a discussion as to whether, seeing that the Corporation license from the Board of Trade for electric lighting purposes had only three years to run, it would be wise to lay down plant and spend £2,000 if the plant would be of no use at the end of that period.

On Thursday last week a Local Government Board inquiry was held *re* several sums to be raised for public works by the Corporation, including £2,500 for the electric lighting of the pier and pleasure gardens.

Bradford.—The Gas and Electricity Committee have decided to reduce the price of electricity for lighting by a ½d. per unit, and have also fixed a sliding scale for motors, making prices range from 2½d. to 1d. per unit.

Brighton.—The Town Council on Thursday last week had a debate upon a proposal by the Lighting Committee to reduce the price of the electric current after the first hour's usage from 1½d. to 1d. per unit. The accounts for the year ended December, 1897, showed that, after making provision for the annual charges for interest and the repayment of loans, there remained a net profit on the year's working of £2,864. Out of this amount the Committee proposed to apply £2,000 to the relief of the rates and to add the £864 to the reserve fund. The Council divided on an amendment by Mr. Buckwell that the price should not be reduced, and this amendment was carried by 18 votes to 17.

Bulawayo.—At a recent meeting of the Municipal Council a letter was read from Colonel Heyman, stating the terms upon which the contractor (being the Electric Light Company), was prepared to supply the light to the Council. This was stated to be 1s. 7d. per unit. It was further stated that the Government was prepared to vest its lighting contract in the Council. This matter was referred to the P. W. Committee.

Camberwell.—The General Purposes Committee has had under further consideration the question of the proposed purchase of the undertaking of the County of London and Brush Provincial Electric Lighting Company, Limited, and has received a statement that the estimated cost of the work done in the parish up to date was £3,200. The committee recommended that the proposed purchase be not proceeded with, and this has been agreed to.

Cardiff.—The Lighting and Electrical Committee has agreed that the conditionally accepted tender of the Atlas Engineering Company, Canton, for the supply of a number of junction boxes for the electrical department be rejected, as the company does not comply with the fair wages clause. The contract has been given to Mr. Wilkinson, of Cardiff.

Dewsbury.—The Electricity Committee has approved of the doubling of the existing trunk mains at a cost of £5,000, of an extension of mains in a part of the borough not yet served at a cost of £2,500, and of the purchase and laying down of an additional engine and dynamo at a further charge of £2,450, including the cost of an extension of the building at the central station. The electrician (Mr. Mitchell) having resigned, to take a situation at Southend-on-Sea, it was decided to postpone the carrying out of the extension scheme until the appointment of his successor. The General Purposes Committee has considered a recommendation that the new electrical engineer should be paid a salary of £200, and be allowed to take a pupil, but has decided to pay £250, and not to allow a pupil to be engaged.

Douglas.—Prof. Fleming was yesterday to have an interview with the Douglas Town Council for the purpose of advising them as to the electric lighting of Douglas.

Dublin.—At the last Corporation meeting the Lord Mayor moved the adoption of a report of the committee of the whole house recommending the application of the Corporation to the Local Government Board for a loan of £20,000 for new electric cables and works connected therewith, and for the establishment of subtransformer stations. A proposal from the Dublin United Tramway Company to take over the lighting of the city on certain conditions, and an offer of a similar nature from Messrs. Jameson, Cobb, Pearson and Co., of London, were considered simultaneously with the report, and his lordship moved that they be taken as read. The report stated the committee considered a report from Prof. Kennedy, consulting electrical engineer, and finally decided on his advice to adopt cables insulated with vulcanised bitumen as made by Messrs. Callender & Co., and of a system of low-tension distribution.

Durham.—The Town Council is considering the question of electric lighting. The Gas Lighting Committee recommended that specifications and estimates be obtained of the cost of erecting plant, but an amendment referring the matter back to the Committee to obtain terms upon which electric lighting companies would supply the Council for street lighting and private consumers was adopted.

Dundee.—Mr. Tittensor, the electrical engineer, submitted a lengthy report to the Gas Committee last week with reference to the extension of the electric lighting area of the city. He gives a statement of the development of the lighting within the old area since the opening of the supply in 1893 as follows:—

	Lamps connected.	Units sold.	Increase.
1893	8,470	66,228	—
1894	11,860	156,843	90,615
1895	14,001	202,437	45,594
1896	17,945	254,278	51,841
1897	22,897	323,187	68,909

The length of streets through which mains were laid for supply up to the end of 1897 was four miles. The extended area gives a total length of street of eight miles. In the new districts he anticipated a demand for 25,000 lamps after five years, exclusive of public lighting. The distribution mains of the new area would be fed from the present generating stations through four sets of feeder mains. The whole of the extended area could be supplied from the present station, and the following additions would be required:—The present engine and boiler house would have to be extended. The additional plant required would be:—Boilers equal to 900 horse-power, engines and dynamos equal to 900 horse-power, together with the necessary steam pipes, pumps, economiser, and switching gear. He estimated the cost of all these extensions as follows:—Distribution mains, £14,400; feeder mains, £4,000; buildings, &c., £3,600; boilers, seatings, and fittings, &c., £1,800; engines, dynamos, &c., £8,000; steam pipes, &c., £1,200; switchboards and instruments, £1,400; economisers, &c., £600—total cost, £35,000. This included spare culverts along the existing tramway routes for the reception of feeder mains in the event of electrical traction being adopted, as recommended by Messrs. Urquhart & Small. The most suitable system to adopt for the extended area would be a three-wire system distributing at 200 volts at consumers' terminals. This would enable the whole of the plant and batteries now in use at the generating station to be used in conjunction with the new plant without much alteration, and would also make the new system of mains gradually take up the increasing load on the old area, which would thus develop itself into a three-wire system at 200 volts similar to the extended area. He did not consider that a higher pressure of supply than 200 volts was necessary within the limits of the extended area, as the higher the pressure adopted, the greater the disadvantage to those customers using arc lamps, in the increased cost of current for the same. At the present time there were 22,897 lamps connected in the old area, of which 16,000 were supplied at the old pressure of 100 volts, the remaining 6,897 being supplied at 200 volts, in accordance with the statutory notice given in June, 1897. It would be of great advantage if the whole were converted into a 200-volt supply, although it would entail serious disadvantages to several of the customers. If a compulsory change were made all over the city, the expense would devolve upon the Town Council, which would include replacing all 100-volt lamps with those at 200. It would also be necessary to exchange all arc lamps burning in pairs at 100 volts for those designed to burn in pairs at 200 volts, and all motors in use at 100 volts would have to be rewound. The total cost of this would be about £1,800. The most serious objection to such a sweeping reform was that those customers (of which there were several) having at present only one arc lamp installed, would be paying at the rate of 9d. per unit for current for the same lamp at 200 volts, being just double their original rate. No doubt this objection would be overcome at no distant date by the introduction of new and improved lamps. He would therefore recommend that all those mains supplying customers at 200 volts be connected up to the new system to be laid as a three-wire system at 200 volts, and those mains supplying the older customers at 100 volts be "inter" connected as a modified five-wire system supplying at 100 volts, until such time that it might become necessary or expedient to gradually change on to the 200-volt supply, after which the whole of the old and new area would resolve itself into one three-wire system at the higher voltage. He recommended that the laying of the mains should be proceeded with gradually as the demand arose, thus spreading the cost over several years. The present requirements would be the extension of the present buildings at the generating station, the laying down of the three-feeder mains to the north, east, and west districts, and the erection of one boiler, engine, and dynamo, with the necessary piping, &c., at a cost of £9,300. The committee resolved to consider the whole question at another meeting.

The Gas Committee recommends that Mr. Tittensor's salary be advanced £50 per annum.

East Grinstead.—There was a long discussion at the District Council last week on the proposition made by Mr. Steer that application be made for a provisional order as soon as the probable cost to be incurred in carrying out a scheme is ascertained. The resolution was carried.

Eccles.—The electrical engineer (Mr. Clirehugh) has reported upon the progress of the electricity works. The buildings had progressed very slowly. The main laying will be commenced during this week. The cables are now all manufactured. Mr. Clirehugh's draft of charges to be made for electrical energy has been approved.

Edinburgh.—The Cleaning Committee recommended the Council to light a number of additional streets by electricity, but after discussion the matter was re-committed. Mr. Mackenzie, in supporting the Committee's proposal, said that the number of lamps sanctioned formerly by the Council, including 37 for Portobello, was 540. The Council sanctioned 91 additional, which included 12 for the Middle Meadow Walk, which had since been withdrawn at the request of the Parks Committee, who considered that the Middle Meadow Walk was not suitable for the electric light. If these 59 new lamps were sanctioned the Electric Light Committee saw its way to reduce the cost per lamp all over the city from £16 to £14. The Electric Lighting Committee recommended that the charge for electric energy as from May 15th next be 3½d. per unit with discount, the charge for each public lamp £14 per annum, and the charge for motor power 1½d. per unit. On the motion of Bailie Mackenzie, the first part of the motion was agreed to, and the second portion was re-committed, in view of the discussion that had taken place on the report of the Cleaning and Lighting Committee.

Folkestone.—At the West Cliff Hotel electricity has been installed throughout. In all there are 640 lights.

Halifax.—The Gas Works Committee entertained the members of the Town Council at a banquet recently, and in some remarks made by Mr. Wilmshurst, the borough electrical engineer, it was stated that the fact that the Electricity Committee had provided for many years extension undoubtedly militated against their making an immediate profit, but he thought there was a prospect of turning the corner this year. The prospects for the future were very good. On March 31st, 1895, they had 92 consumers; a year later they had 179; on March 31st, 1897, they had 235, and for the year ending March 31st, 1898, 309. So that although they had not made a profit, yet they were building up a very sound business.

Hastings.—The Electric Light Company is to light the front during April and May at £4 per lamp per month, and during June and July at £3 per month.

Hereford.—The Electric Lighting Provisional Order has been referred to a special committee for consideration and report.

Ilfracombe.—The District Council proposes to expend £10,000 in the construction of electric plant, &c., for the purpose of illuminating the town by the electric light.

Inverness.—The Town Council has been discussing the feasibility of introducing the electric light into the town. Messrs. Fraser & MacCallum, solicitors, had written to the effect that a local company was about to be formed with the view of lighting the borough and vicinity by electricity, and asking if the Council would agree not to oppose the undertaking. It was considered by the Council that the works should be done by the municipality, and a committee is to be appointed to ascertain whether there is such a demand for the light as to justify the Council in taking steps to introduce it.

Lancaster.—Mains are to be laid for supplying current to the Bowerham Board School. The Lighting Committee recommends the Council: "That the Electricity Committee be asked to discontinue the charging of rent for the street arc lamps, in order to place a larger sum of money at the disposal of this Committee for street lighting purposes." The consideration of the matter is to be deferred for six months.

Leith.—The Town Council has resolved: "That, owing to the great cost of carrying out the electric lighting scheme, and the probability that, for a number of years at least, it will be a serious burden upon the ratepayers, the Electric Lighting Committee be instructed to use the utmost economy, consistent with efficiency, in carrying out the work, and that no new expenditure be incurred beyond that already sanctioned without first reporting and obtaining the authority of the Town Council." The chairman remarked that the estimates had already been cut down by £3,000.

Lewes.—A special meeting of the Council is to be held to consider what steps shall be taken regarding the electric lighting provisional order when it has been confirmed by Parliament.

Liverpool.—The City Council has resolved that from April 1st, 1898, the prices to be charged for the supply of electrical energy at a pressure of 230 volts be:—For general lighting, 5d. per unit for each unit up to 1,000 units per quarter, and 4d. per unit for each unit in excess of 1,000 units; for Corporation departments, 4d. per unit; for street lighting, 3d. per unit; for power purposes, 2d. per unit.

London County Council.—The Council has decided to lend £13,660 to the Vestry of Islington for electric lighting extensions. The Finance Committee stated that the Vestry proposed to add to the Eden Grove generating station two water-tube boilers, one 500-H.P. engine, and one 300-kilowatt alternator, and to extend the mains in Liverpool, Wellington, and St. James's Roads. The Council is withholding its consent from the County of London Company re-laying mains in several Dulwich and Peckham roads for the present, on account of the appointment of the Parliamentary Committee on electrical matters which is shortly to sit. It will be remembered that last February the Council accepted the tender of the National Electric Free Wiring Company to carry out the electric light installation at the chief station of the fire brigade for £992, less the amount of the wages of certain of the Council's employés to be engaged on part of the work. Referring to this matter, the Fire Brigade Committee has now reported that, on further consideration, it has come to the conclusion that it would be better for all the work to be carried out in its entirety by the company's employés. The company had acquiesced in this, and the Council's servants employed on the work had been withdrawn.

Lyndhurst.—Messrs. Warburg, Dymond & Co., of London, have informed the New Forest District Council that it was proposed to form a limited liability company with the object of putting down a plant for the electric lighting of Lyndhurst, and that they purposed purchasing a suitable site at Glasshayes. It was their intention to apply forthwith for a license from the Board of Trade. The Lyndhurst Parish Council is to have the opportunity of considering the matter and taking the opinion of a parish meeting upon it.

Oldbury.—The District Council has withdrawn its opposition to the provisional order of the Midland Corporation, Limited.

Ossett.—The Town Council has received a provisional order authorising the Council to lay down electric lighting plant, and to supply the borough.

Paddington.—The Guardians' Visiting Committee is inquiring into the cost of installing the electric light in the north block of the workhouse, the chapel, and the dining hall.

Rathmines.—At the last meeting of the Commissioners Mr. Booth called attention to a report made about 12 months ago by Mr. Hamwood, electrical engineer, setting out two methods by which the electric lighting of the township might be carried out. Mr. Hamwood was in Dublin in January last, and then promised to draw up an amended report for 25 guineas. In that report several of the previous proposals would be altered, owing to the improvements that had recently taken place in this branch of science. He proposed that the board should accept this offer. It was resolved to request the Electric Lighting Committee to meet and consider what steps the board should take to save their rights under the order in Council, and to take such action as they may deem advisable.

Reading.—The Highways and Lighting Committee has received a letter from the Board of Trade, enclosing an amended description of the systems proposed to be adopted for the supply of energy under the Reading Supply Order, 1893. The committee also received Mr. Bowen's report, and on his recommendation approved the proposed works, subject to a number of amendments and conditions suggested by him.

Salford.—The Council has approved the proposal of the Electric Light Committee to purchase land abutting on Bedlam Lane, off Strawberry Road, as a site for a new generating station for the electric light. The Council were asked to vary the resolution of the Council of January 5th last, authorising an application to the Local Government Board for power to borrow £50,000 for the purposes of electric lighting. It was now, under different circumstances, proposed to ask for £33,000. The resolution was adopted.

Shoreditch.—The cost of laying larger cables in Curtain Road, Great Eastern Street and Old Street (authorised by the Vestry) will be about £2,000.

Southall.—The Town Council has received a letter from Messrs. Brewer & Meaby, with reference to supplying electric light. This has been referred to the Committee.

Southport.—The Gas Committee recently opposed a proposal on the part of the Electricity Committee to add 42 arc lamps to the street lighting, and it was withdrawn. The salary of the electrical engineer (Mr. C. D. Taite) is to be advanced from £230 to £280.

Stirling.—Mr. R. F. Yorke has submitted a lengthy report to the Police Commissioners on the water power available at Touch for the electric lighting of Stirling. He shows that by utilising the water power which exists in connection with the Touch reservoirs, they could, with a moderate expenditure of some £13,000 to £14,000, deal effectually with the lighting of the extended area, viz., 8,000 lamps connected; and that by charging for the private lighting at the rate of 4½d. per unit, there would be a considerable surplus as soon as the total number of lamps have been taken up. His estimate for capital outlay is as follows:—

	£
Two 54-H.P. turbines, with frames, suction pipes, delivery and erection..	540
Two dynamos	380
Switchboard	80
Buildings..	200
Fittings, &c.	20
Underground cable—3½ miles concentric 37/13, with laying and jointing..	2,495
Accumulators—250 cells = capacity 308 amperes, for three hours, or 154 amperes for six hours = 4,466 lamps for three hours	2,525
Stands and converting buildings	100
Allow for continuation of two 12-inch pipes, with laying and jointing..	200
Allow for trench for cables	100
Engineer's fees and contingencies ..	410
	£7,000
Allow for distribution—mains, meters, &c.	6,500
	£13,500
Working expenses	£650

For repayment of generating and distributing plant, with interest, allow 5 per cent. of total cost of £13,500 = £675. Although 8,000 lamps connected is a large proportion for the number of the inhabitants, it will be possible, by utilising the additional power from another reservoir, to supply current for another 4,000 lamps, *i.e.*, a total of 12,000 lamps connected. Mr. Yorke's scheme includes turbines by Messrs. Gilkes, dynamos by Laurence Scott & Co., cables by the British Insulated Wire Company, and accumulators by the Chloride Electrical Storage Syndicate. The Commissioners remitted it to the Lighting Committee to see whether the necessary consents and wayleaves can be obtained, and to report, so that they are not at present committed to anything.

Swansea.—Mr. Manville's report on the electric lighting scheme puts the capital expenditure, after adding 7½ per cent. for contingencies, engineering, &c., at £35,936. In his estimate of the revenue derivable, he gives 15,700 8-C.P. lamps for private lighting, which would, at 4½d. per unit, bring in £4,444, whilst the public lighting would bring in £733, making a total of £5,177.

Wednesbury.—The Town Council last week resolved by eight votes to five, to make application for a provisional order. There was a lengthy discussion.

Woking.—The Electric Supply Company has undertaken to have all the street lamps overhauled immediately and renewed where necessary.

Yarmouth.—The Council has decided to borrow £4,800 more for further additions to the electric lighting plant, making £40,000 in all. In the last three months considerably over £500 has been earned beyond the actual cost of production. Mr. George Bryant, assistant engineer of the electrical supply station, has been appointed chief engineer, in succession to Mr. A. W. Ranken, who had resigned.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Argentine. — At last week's meeting of the Anglo-Argentine Tramway Company, held in London, the Chairman said that with regard to the question of electric traction, the Board had come to the conclusion that favourable results might be obtained by using electricity on certain parts of the line. An offer had been made by a body of financiers to find the necessary capital for the conversion of the system, but he was unable at that moment to enter into details. The shareholders would be consulted before any binding agreement was entered into.

Blackpool.—At last week's Council meeting Mr. J. Brodie, the chairman of the Electric Lighting and Tramways Committee submitted the report of a deputation which had visited Paris, Berlin, Hanover, &c., to study the system of tramway traction. It was the unanimous recommendation of the deputation that the overhead system be adopted. If the Council favoured the accumulators, well and good, but they must be prepared to run the tramways at a loss.

Brighton.—The Council has refused to grant a license to a Montreal firm to construct and operate an electric trolley system in the borough.

Derby-Ashbourne. — The promoters of this proposed light railway have decided to apply to Parliament for further powers, this step having been rendered necessary by the decision recently arrived at to alter the original plans as to the termini.

Dudley.—On Tuesday last week the mayor stated to the Town Council that the previous day Mr. Albright, Mr. Addenbrooke, and Mr. Lowe, of the Midland Electric Power Distribution Company, had attended a meeting of the Electrical Railway and Tramway Committee and quoted prices for local supply of electricity. The company would supply electricity and lay mains for the first 100 hours at 5½d. per unit, and at 2½d. per unit for subsequent supply. If the Corporation provided the mains the prices would be 5d. and 2d. The company would supply the electricity in bulk at a uniform price of 3½d., they laying the mains; or 2¾d. if the Corporation laid the mains. The price for public lighting would be 1·6d per unit, and for electric traction 1½d. per unit. It was understood that the current would only be brought to a given point in the town. Subsequently Alderman Garratt and Alderman Bagott were added to the Committee, and Alderman Bagott made a hopeful statement as to the future of the tramway undertaking. He was, he said, sure that with good management the proposed electric tramways would be a source of great profit to the borough. The Council confirmed formally the recommendations to take the necessary steps for taking over the lines.

Dudley and Stourbridge.—The British Electric Traction Company, which recently purchased the Dudley and Stourbridge Tramways for £44,000, has entered into a contract for the transposal of the existing steam tramway from Stourbridge to Hart's Hill, Dudley, into an electric system. A site for a power station has been secured by the company near Canal Street, Brierley Hill, and electric cars will be run from Hart's Hill to Stourbridge within about six months, and through Dudley as soon as, and if, arrangements can be effected with the Dudley Corporation. The contract for the alterations to the permanent way and for the electric equipment has been secured by Messrs. Dick, Kerr & Co. It may be remembered that the British Electric Traction Company, after acquiring the line from Stourbridge to Hart's Hill, obtained an order to construct a new tramway to Cradley Heath from Dudley, and to Kingswinford and Stourbridge. The Dudley Town Council, however, are opposing the Dudley and Cradley Heath order given by the Light Railway Commissioners on the ground that they are desirous of making the line themselves. The lease of the portion of the Dudley and Stourbridge line from Dudley to the boundary at Hart's Hill expires at the end of about five years, and it is the intention of the Dudley Corporation, as the matter stands at present, to seek to work that portion also.

Folkestone.—The promoters of the Folkestone District Light Railways have intimated their intention of not proceeding with the application to the Commissioners for the construction of the proposed railways in Folkestone, Sandgate and Hythe.

Liverpool.—At the last City Council meeting, Sir Arthur Forwood, chairman of the Tramways Committee, moved a recommendation that the necessary steps be taken to construct a new road continuing Park Road into Aigburth Road. They were laying down a new system of electric tramways to the Dingle. At present the lines running from Peel Street, Park Road, to the Dingle dipped 15 feet, and from the Dingle to Aigburth Road they rose again 12 feet. The suggestion of the committee was to acquire the property between the corner of Peel Street and Aigburth Road voluntarily, so that they might then make a direct connection between Aigburth Road and Park Road almost on a dead level at a reasonable cost. After discussion the proposal was taken back.

Llandudno.—The Town Council last week agreed to a scheme promoted by a syndicate for the construction of a light railway connecting Colwyn Bay, Llandudno, and Deganwy.

Newcastle.—At a meeting of the Tramways Committee on 4th inst., Mr. Laws, city engineer, reported that the total amount of double track upon the seven sections already decided on by the committee amounted to 12 miles 394 yards. He estimated that the cost of laying down this distance, either with cables or the overhead electrical system, would be £245,000. It was agreed, acting under a resolution passed by the Council, that Mr. Laws should be requested to furnish the committee with the names of two experts—one to advise the committee with respect to the cable, and the other with respect to the overhead electrical system. Mr. Laws will present the names of the experts whom he deems most suitable for this work to the next meeting of the committee, to be held on May 3rd. The resolution provides that the committee "shall have the power to engage an expert or experts to advise with respect to the best system to be adopted, such experts to be gentlemen who are not connected financially with any system of tramways, or any company for the promotion of tramways."

Northampton.—In our note regarding the Northampton tramways last week, the word Nottingham in line 3, should, of course, read Northampton.

Norwich.—Notice appeared in the *London Gazette* last Friday of application being made by the Norwich Electric Tramways Company for additional provision for leave to introduce in their Bill various new powers for street widening and alteration, and for deviation of the authorised tramway.

Nottingham.—The report of the Committee recommending electric traction, which we briefly referred to last week, came before the Town Council on 4th inst., and after lengthy consideration had been given to the matter the following resolution was unanimously passed:—"That the report of the Tramways Committee now presented to the Council be received and adopted as and for the first reading, and that the second reading thereof be taken at the quarterly meeting of the Council in May next; that in the meantime the Tramways Committee be authorised to instruct the city engineer to proceed with the necessary surveys, plans, and sections which will be required for the purpose of enabling the Council to give notices and take all proper steps to promote a Bill during the next session of Parliament for carrying out the recommendations of the Tramways Committee now laid before the Council if that course be ultimately adopted."

Salford.—A sub-committee has been appointed by the Highways Committee of the Town Council to report upon the probable cost of taking over and working the tramways, and also the cost of electric traction. It has been reported to the Highways Committee, on the authority of Mr. Alderman Milling, that it is not the intention of the Manchester Corporation to engage an expert to advise them, but they will reply upon the advice of their own electrical engineer in any matters relating to the future working of the tramways of the city. Further that Dr. Hopkinson has been engaged by the Manchester Corporation to give evidence on their behalf before the Parliamentary Committee against the Manchester Carriage and Tramways Company's Bill.

St. Helen's.—The Electric Lighting and Traction Committee of the St. Helen's Corporation has definitely resolved that electricity on the overhead system be adopted and introduced as the motive power on the Corporation tramways, and that accordingly the town clerk be instructed to apply to the Board of Trade for their consent to the use of electricity for the trams, and also for their sanction to borrow £25,000, the estimated cost of the generating works and plant, and the distributing plant necessary for this purpose.

Stretford.—The District Council has decided to give notice to the Manchester Carriage Company that in July next, directly the statutory term of 21 years expires, it will promote a Bill in Parliament empowering the Council to work the tramways by mechanical power, including electrical haulage, and to borrow funds to defray the cost thereof.

Waterford.—The Corporation after an interview with Mr. Palmer in reference to his application for an electric tramway concession, has granted same on the following terms:—That a lease be granted for 75 years at a nominal rent for the first 10 years, and that subsequently a rent amounting to 5 per cent. on the amount of the dividend paid the shareholders be reserved to the Corporation. That the concession be from the Terminus of the Waterford, Dungarvan and Lismore Railway to the Bridge, along the Quays, the Mall, Parnell Street, portion of the Manor, Lombard Street, William Street, and up Newtown as far as the Municipal Boundary. The Corporation to reserve to themselves the right to seek for Parliamentary powers to purchase the tramway after the expiration of 50 years. All plans and specifications to be subject to the approval of the Council. Matters of detail to be subsequently arranged.

TELEGRAPH AND TELEPHONE NOTES.

Bristol.—The report of the Bristol Chamber of Commerce which will be presented to the annual meeting next week traces the rapid growth of the telephone in the West of England and South Wales. In 1893 there were 4,470 lines in this division, and there were now nearly 9,000, and the rate of increase was still growing. In Bristol, after considerable delay, the underground system was now being actively carried out, in Bath the work was approaching completion, and in several other towns in the district arrangements were in progress for substituting underground cables for poles and wires. Tenders for a large new building in a central position in Bristol were now under consideration by the London Board; there would be a very spacious switch room, and a large switchboard with all the latest improvements for ensuring correctness and rapidity in the transmission of messages. Unexpected delays had arisen in opening exchanges at the group of Wiltshire towns, but the Post Office was now constructing the connecting trunk between Bradford and Bath, and in a few weeks several of these towns would have exchanges opened in them and others would soon follow. The group included Bradford, Trowbridge, Melksham, Devizes, and Warminster in Wilts, and Frome in Somerset. An exchange had been opened at Pershore in connection with Evesham and Worcester. Hereford, after many difficulties and delays, had been opened, and Chippenham, Cirencester, and Dursley would soon follow. Efforts were being made to introduce the telephone at Wells, Glastonbury, Street, Cheddar, and Axbridge in Somerset. In Cornwall the use of the telephone was rapidly extending. Last year Falmouth and Penzance were the only exchanges in the county, now Truro, St. Austell, Fowey, and Par had been opened. And Newlyn and other towns were likely soon to be added to the list. In Devonshire exchanges had been opened at Barnstaple and Bridleigh, Salterton, and it was hoped that Bideford [and neighbouring places would soon follow.

Delays in Australian Telegrams.—Although no official notifications have been received from Berne, still we can gather from the Australian newspapers recently to hand that the Australian trunk landlines continue to be periodically interrupted. On February 26th we read, that European cable messages were subject to delay on the Port Darwin line. On March 1st the "telegraphic communication on the Port Darwin line which had been temporarily interrupted was again restored." Under date of March 7th we read that the Roebuck Bay landline had been interrupted for two days.

It will be remembered that the Roebuck Bay line is supposed to afford an alternative to the Port Darwin line; which latter on March 8th was interrupted near Port Darwin, and the cable traffic had to be diverted *viâ* the Roebuck Bay landline, then presumably convalescent. It is painful to find that as concerns this latter line, the Postmaster-General of South Australia expresses himself in ungrateful terms. He says it "is acknowledged to be the worst line in Australia, the many fogs on the coast rendering it very hard to get signals through." This may, however, only be the expression of friendly rivalry, as judging from the reports concerning the Port Darwin landline, for which he is responsible, it is difficult to say which is the worst of the two lines. On February 14th, Sir Charles Todd, in referring to the delay in the transmission of cable messages to England, is reported to have said: "the interruptions caused by the crossing of creeks and rivers have been very few. In fact, I can only remember four arising from that cause." It would be interesting to know the causes of the numerous other interruptions and delays on this line, which this gentleman appears to ignore, as we find that for the six months before the date on which Sir Charles Todd is reported as above, there were no fewer than 18 days on which the Port Darwin line was either totally interrupted, or on which messages on that line were greatly delayed. There may possibly be other interruptions and delays of which we are not informed, but this is only due to the fact that the authorities in Australia appear to neglect the rule of the International Telegraph Convention, of which they are signatories, by omitting to advise the Bureau International at Berne of such occurrences. On examination we find that since the beginning of September last there have been 24 days on which interruptions or serious delays have occurred on the Port Darwin line, and 17 days of interruptions or serious delays on the Roebuck Bay line; these interruptions sometimes occurring simultaneously, and the total of 41 days is probably much below the actual record of default. We observe that the public in Australia are at length making serious protest against the present inefficient system.

Dudley Telephones.—The Council has been considering the question of the telephone service. The granting of licenses is favoured, and the applications of the New Mutual Telephone Company and the Glasgow Corporation are supported.

Havana and Key West Cable.—We understand that the telegraph cables between Havana and Key West were interrupted and restored on Wednesday. This is the first interruption of communication since the repairs carried out by the Silvertown Company in 1882.

Hong Kong-Manila Cable.—The Eastern Extension, Australasia, and China Telegraph Company, Limited, with a view to improving telegraphic communication with the Philippines, by making it independent of the landline between Cape Bolinao and Manila, have extended their cable from Hong Kong to Manila direct.

CONTRACTS OPEN AND CLOSED.

OPEN.

Accrington. — April 19th. The Corporation wants tenders for the supply and erection of three sets of steam dynamos, each set consisting of a triple expansion condensing steam engine of the inverted vertical type, 90 I.H.P., and of a shunt wound dynamo. Also a feed water heater, storage battery having a capacity of 750 ampere-hours, switchboard instruments, apparatus cables, wires, street boxes, connections, &c. For further particulars see our "Official Notices" April 1st. Consulting engineer, Mr. J. N. Shoolbred, 47, Victoria Street, S.W.

Belfast.—April 18th. The Harbour Commissioners are inviting tenders for the supply and erection in the electric light station, Abercorn Basin, Belfast, of three compound, two-crank, self-lubricating, single-valve quick revolution vertical engines, each capable of developing 70 H.P., with a steam pressure of 130 lbs. per square inch. Also for three belt-driven, continuous current, series wound dynamos, capable of giving 15 amperes, 2,850 volts, at a speed not exceeding 800 revolutions per minute for 18 hours continuous running, without undue heating. Specification and further particulars from the harbour engineer, Mr. G. F. L. Giles. See our "Official Notices" April 8th for particulars of these two contracts.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Bootle.—April 25th. The Corporation wants tenders for the supply and erection of arc and incandescent lamps, lamp-posts and accessories. Engineer, Mr. T. L. Miller, Liverpool. See our "Official Notices" this week.

Edinburgh.—April 23rd. The Midlothian and Peebles Lunacy Board is inviting tenders for the installation of electric light in the Asylum at Rosslynlee, near Edinburgh, including (1) generating plant, accumulators, switchboard, &c.; (2) wiring, fittings, &c. Particulars may be obtained on application to Prof. Bailey, Heriot-Watt College, Chambers Street, Edinburgh.

London.—May 17th. The Bethnal Green Board of Guardians invites tenders for the supply of plant, and installing the electric light at the new infirmary, Palestine Place. Plans, &c., to be obtained from the architects, Giles, Gough & Trollope, 28, Craven Street, Charing Cross, W.C. See our "Official Notices" this week for particulars.

Milburn, Esher.—Tenders are being invited, says *Daily Tenders*, for the running and maintenance for five years of an electrical installation, comprising gas engines, accumulators, dynamos, &c., and connected machinery. Further particulars from Messrs. O'Gorman and Cozens-Hardy, 21, Embankment Gardens, S.W.

Roumania.—April 30th. Tenders are being invited until the 30th inst. by the Roumanian Post and Telegraph Authorities in Bucharest, for the supply of 50 tons of galvanised iron wire, 10 tons of galvanised steel wire, and 5 tons of tinned copper wire. Particulars may be obtained from, and tenders to be sent to, La Direction Générale des Postes et Telegraphes, Bucharest, Roumania.

Sunderland.—April 29th. The Corporation is inviting tenders for the supply of a high-speed 225-kw. steam dynamo, and two Lancashire or Galloway boilers. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" this week for particulars.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

Brighton.—The Council has accepted the tender of Messrs. Willans & Robinson for the supply of two steam dynamos for the electricity works for £9,591.

Derby.—The Town Council has given the contract for the supply of carbons to the English Carbon Company.

Rochdale.—The Council has accepted the tender of of Messrs. Siemens Bros. & Co. to supply steam dynamos (Belliss engines), balancer and booster, conditionally upon the granting of authority by the Board of Trade and the Local Government Board.

FORTHCOMING EVENTS.

1898.

Monday, April 18th, 8 p.m.—The Northern Society of Electrical Engineers, at Manchester. Paper on "Commercial Forms of Electrical Resistances used for Lighting and Power Purposes," by Mr. Ll. B. Atkinson.

At 8 p.m.—Society of Arts. "Sources of Commercial India-Rubber," by Dr. D. Morris, C.M.G. Two Cantor Lectures.

Tuesday, April 19th, at 8 p.m.—The Institution of Civil Engineers. Paper to be discussed:—"The Electricity Supply of London," by A. H. Preece, Assoc.M.Inst.C.E.

Thursday, April 21st, at 8 p.m.—Chemical Society, Burlington House. Papers to be read:—"The Carbohydrates of Barley Straw," by C. F. Cross, E. J. Bevan, and Claud Smith; "Isomeric Bornylamines," by M. O. Forster, Ph.D.; "Some Derivatives of Benzophenone," by F. E. Matthews, Ph.D.; "Researches on Camphoric Acid," by S. B. Schoyver, Ph.D. Ballot for the election of Fellows.

At 8 p.m.—The Institution of Electrical Engineers. "Cost of Generation and Distribution of Electrical Energy," by R. Hammond, Member. (Continuation of discussion.)

Friday, April 22nd, 5 p.m.—Physical Society. "On a Method of viewing Newton's Rings," by the Rev. T. C. Porter.

Tuesday, April 26th, at 8 p.m.—The Institution of Civil Engineers. Annual general meeting to receive report and to elect council and auditors.

NOTES.

The Electrical Resistance of Thin Films.—An article in the *Physical Review* (America) for January, by Isabelle Stone, gives an interesting account of experiments on the conductivity of thin films of silver deposited on glass by the Rochelle salt process. Many experimenters have endeavoured to construct portable standards of high resistance by means of lines and films of black lead, and of conducting powders, and have discovered how unstable such devices are. The authoress of the present paper has in each case calculated the thickness of the film from the area and mass of the deposited silver, assuming its density to be that of solid silver, and has given the resistance corresponding to that thickness. From films 10 cm. long by 1 cm. wide, and varying in thickness from about 1 to 22 millionths of a centimetre, she obtains two principle results. One is that the measured resistance is always enormously higher than the calculated, being in one case more than 100,000 times as great, and the other, that the resistance of the film always drops rapidly after formation, and continues to do so for an indefinite time, excepting in the case of very thin films, which could not be permanently maintained, and some few whose resistance, after a few days, began to increase. The changes were rapidly accelerated by heat. The experiments appear to show that the metal is deposited in an only partially coherent condition, and gradually settles down into a more compact mass. It would be interesting to know if magnetic oscillations affect the conductivity of such a film. The experiments were suggested to the authoress by Prof. Michelson, who, as is well known, uses semi-transparent films of this kind in his interferometer.

Does a Diaphragm Exist Preventing Diffusion, but not the Passage of an Electric Current?—This subject is discussed by K. Ochs in the *Chemiker Centralblatt*, No. 1, p. 289. A diaphragm that would prevent diffusion, but would allow the passage of a current, might be either (1) a membrane not permeable by the electrolyte, but permeable by the ions; or (2) a membrane permeable by the ions, and which would absorb the electrolyte, but not allow its transfusion; (3) or a membrane not permeable by either electrolyte or ions, but which allows passage of the ions when these have been deprived of their charges. Membranes of the first class are at present unknown. Those of the second order appear to be formed by precipitation of both ions in the pores of the membrane, as, for example, in the Reynier cell (a Daniell cell in which potash replaces dilute sulphuric acid), in which copper oxide forms in the pores of the cylinder, dividing the copper sulphate and potash solutions. With the continual formation of the precipitate in these cases, the resistance increases, so that any advantage obtained by the non-diffusion of the electrolyte is completely nullified. A membrane of the third order might be formed if a sufficiently thin film of mercury could be obtained, as a metal like zinc could diffuse through such a film. It does not appear, however, that such a membrane would be of any practical value. Diaphragms of the required kind for practical purposes are therefore at present unknown.

Some Researches on Electrical Conductivity.—Carl Fritsch has determined the conductivity of a number of solid substances, taken either in the form of precipitates or compressed plates, and further examined the effect which the addition of small quantities of a foreign solid has on the conductivity of the pure solid under examination. The effect of the addition of small quantities of a second salt to that which is under examination, is, in nearly all cases, to largely increase the electrolytic conductivity of the latter; this would appear to be best explained by assuming the formation of a solid solution, in which the solvent, lead chloride, for example, causes ionisation of the dissolved salt, say, potassium chloride. It is not impossible that the conductivity of the solid salts themselves is caused by the presence of traces of impurities, but this point would require specially investigating in each case. The conductivity increases rapidly with rising temperature, but the changes in the temperature coefficients are much smaller than those in the conductivities themselves. The above is an abstract from the *Annales de Physique et Chemie* (II.), No. 60, pages 300—313. Some interesting data have also been obtained by E. H. Loomis, and are given in the *Annales de Physique et Chemie*, (II.), No. 60, pages 547—551. Amongst the results the following are of interest:—

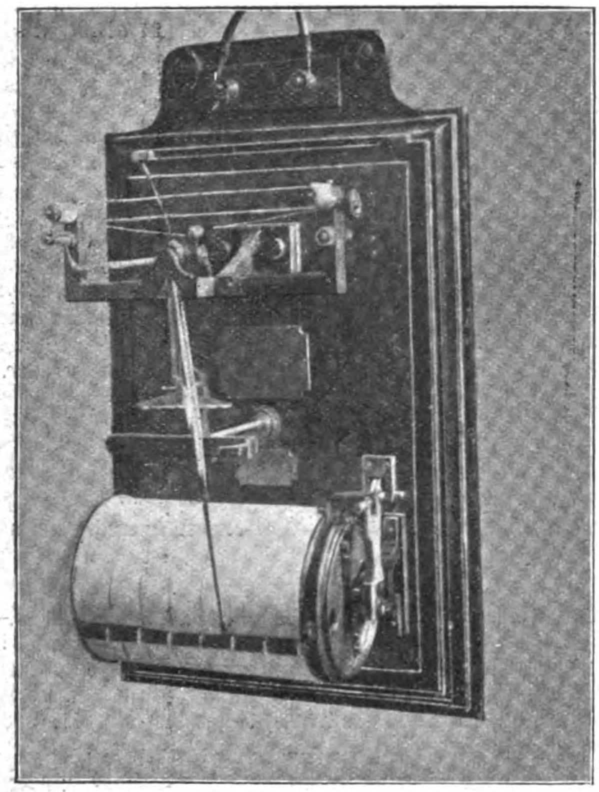
	Sp. Gr. 18°/4°.	K × 10^7 at 18°.
$NaOH$	1·0418	145
KOH	1·0481	170
HCl	1·0165	279
HNO_3	1·0324	278
$1/2H_2SO_4$	1·0306	183
$1/2C_2H_2O_4$	1·0199	55

The electrical conductivities are given in mercury units of the solutions examined.

The Chemical Action of Electrical Oscillations.—This interesting subject has been carefully studied by Alexander de Hemptinne. The apparatus employed for the production of the oscillations was similar to that of Lecher (*Annales de Physique et Chemie*, 1890 (II.) No. 41, 850), and allowed of the ready alteration of the wave length. A Wimshurst machine driven at constant speed by a motor was employed in most cases, but where greater tension was required, a Tesla transformer was used. Researches with ammonia at pressures of 5 mm., 15 mm., and 50 mm., showed that the velocity of decomposition decreases with increasing pressure, and a maximum was obtained in each case some time after the commencement of the decomposition, after which it decreased, indicating a final equilibrium. The velocity is also markedly influenced by the energy of the discharge. The percentage of ammonia finally decomposed varies with the pressure, being about 50 per cent. at 49 mm., and 95 per cent. at 20 mm., but the values do not agree with the expression $p_3{}^2 = k\,p_1\,p_2{}^3$, which should theoretically obtain in the case of a heat dissociation. The decomposition is further lowered by the addition of nitrogen or hydrogen, the latter having, as expected, the greater effect, but the quantitative results are not in accord with theoretical deductions. Under the influence of electrical oscillations, nitrogen and hydrogen combine to the extent of 3 or 4 per cent., the final quantity being apparently almost independent of the pressure. In all these cases, no action occurs unless the tube containing the gas becomes luminous; and it was observed that one tube may screen another, so that if two tubes at slightly different pressures be placed between the plates and the discharge adjusted so that only one tube lightens, a slight increase of pressure in this tube causes it to become dark, and the second tube to lighten and be decomposed. Carbon bisulphide is also decomposed, the velocity being well represented by the equation $dx/dt = k\,(a - x)$. Some thick liquids, such as glycerol, exhibit an increase of vapour pressure when exposed to the action of the oscillations, a similar effect occurring with oxalic acid, whilst calcium chloride appears to be entirely unaffected. The above is an abstract of a paper in the *Zeitschrift fur Physikalische Chemie*, 1897, No. 22, pages 360-372.

Lecture.—Bailie Mackenzie, convener of the Electric Lighting Committee of Edinburgh Town Council, on 11th inst. addressed the members of the Edinburgh Association of Science and Arts on "Progress of the Electric Light in Edinburgh."

Continuous Recording Voltmeter.—The use of recording voltmeters, as at present made, necessitate for every instrument the filing of 365 charts every year, as well as daily attention and changing of the same. It is true that there is an instrument in the market with a continuous strip which obviates the daily attention but does not reduce the trouble of keeping the records. To improve this, the engineer at the Cambridge Electricity Works devised and adapted instruments already in use to run on the same chart for a week.



The principle of moving the drum along its spindle most naturally suggested itself, and as a matter of fact was included in the application for patent, but to do this would render the horizontal length of the instruments much greater, and would not admit of the ready adaption of existing instruments to the continuous movement. The arrangement of cams and general principle is said to be shown on the accompanying illustration, but this is open to doubt. We understand that the principle is patented, and is applicable to most recording instruments.

Workmen's Compensation Act and Electricity Works.—At the St. Pancras Vestry's meeting of Wednesday evening it was reported with reference to the Workmen's Compensation Act, 1897, which comes into operation on July 1st next, that a letter had been received from the Home Secretary, in reply to a communication from the Vestry, stating that "he is advised that electric lighting works, where electricity is generated by the use of mechanical power, and is supplied to consumers, are factories within the Factory and Workshops Acts, and therefore the Workmen's Compensation Act will apply in all such cases."

The Shannon Electric Power Scheme.—A specially convened meeting of the Limerick Fishery Conservators was held on 7th inst. to hear a deputation from the Shannon Electric Power Syndicate with reference to the pending scheme for utilising the River Shannon in the production of electricity. Lord Lurgan, Colonel Sir Gerald Dease, Mr. H. J. Fuller, engineer, and other directors, attended to explain modifications of the original scheme. That scheme proposed the impounding of Lough Allen, and the conversion of the lake into a storage reservoir, the waters to be utilised on the gravitation principle. In reply to questions, Mr. Fuller said the horse-power to be used all the year round at the works at Castle Connell would be 5,000, the *maximum* being 10,000.

The Economy of the Corliss Engine.—The success of the Corliss engine, as a machine in respect of its steam economy, has, in a sense, not been an unalloyed blessing. That the engine was economical in steam may have been true, but the credit was given to the principle of variable expansion and sharp cut-off. Designers of engines sacrificed everything to a sharp cut-off corner in the indicator diagram, and this was very greatly over-rated, as though special economy arose from it. The claims of the Corliss engine are discussed by our American contemporary, *Machinery*, and the true cause of economy announced, or rather, re-announced. This, of course, is the use of separate valves for steam and exhaust, and the position of the exhaust valve on the lower side of the cylinder, whereby it is enabled to more readily drain the cylinder of water. If the ordinary arrangement be noted, it will be seen that the exhaust valve is so placed as to at once catch any water shot into the cylinder from the steam valve, and also to drain any water which tries to collect in the cylinder. The outrush of the exhaust carries a large proportion of water with it before re-evaporation can occur during the exhaust stroke. This is the great reason for economy. With exhaust valves placed in the cylinder covers, and thus not at the lowest part of the cylinder, we think there would be far greater steam consumptions registered. As we have already observed, the economy of the Corliss engine, really due to good valve arrangement, was long credited to fanciful notions as to shape of cut-off corners, and variable expansion, as though, for example, an automatic variable cut-off could have much influence on the economy of a cotton factory engine, which scarcely varies its power the day through; and the Corliss engine is not the only example showing wrongly credited economies.

Caoutchouc and Gutta-Percha Cements.—A gutta-percha cement for leather is obtained by melting together 100 parts gutta-percha, 100 parts asphalt or pitch, and 15 parts oil of turpentine. It is to be used hot. Elastic gutta-percha cement, especially for fixing soles to shoes, which does not crack in bending, on account of its great extensibility, is, according to an article in the *Färben Zeitung* translated in the *Scientific American*, prepared by dissolving 10 parts gutta-percha in 100 parts benzine and pouring the solution into 100 parts linseed oil varnish, shaking well. The leather must be roughened before using this cement, in order to insure greater durability. By a caseine-borax cement a handsome surface gloss is imparted to the leather. The borax is dissolved in boiling water and the borax solution poured into freshly prepared caseine. The durable thick cement is very serviceable. Good caoutchouc cements, for rubber strips or rubber goods on metal, are obtained by dissolving shellac in ten times its weight of ammonia. After standing for three to four weeks a transparent putty results, which is used without heating. The cemented places soften at first, but become hard and firm after evaporation of the ammonia, which may be assisted by heating. This cement is watertight and gasproof, and is also useful for hard rubber articles. A cement made of a mixture of gutta-percha with asphalt is serviceable for the same purpose. This has to be applied hot and the pieces are to be pressed together. Very useful cement for leather belting is manufactured by kneading 10 parts carbon bisulphide and one part of oil of turpentine with gutta-percha until a thick paste results. The portions of the leather where the cement is to be applied must be unoiled and roughened; the cement is put on and the ends are pressed together until the binding agent has become dry. Directions for caoutchouc cements are: 100 parts finely cut caoutchouc, 15 parts resin, 10 parts shellac, dissolved in sulphide of carbon. One part caoutchouc, seven parts mastic, and 50 parts chloroform, left to stand several weeks.

The Civil Engineers' Incoming President.—At the recent banquet of the Institution of Civil Engineers, Sir J. Wolfe Barry announced Mr. W. H. Preece, C.B., as the incoming president, and he dwelt upon the fact that Mr. Preece will be the first electrical engineer to occupy the chair. This may be taken as an index of the important position occupied by electrical science to-day in all branches of engineering, and we congratulate Mr. Preece upon being the first of a lengthy list of coming electrical presidents of this Institution.

A New Application of the Röntgen Rays.—The *Times* correspondent at Vienna says that some interesting particulars of a new application of the Röntgen rays for curative purposes were communicated by Dr. Edward Schiff, lecturer at the Vienna University, at the last sitting of the Imperial and Royal Medical Society. A series of experiments conducted by Dr. Schiff and his assistant proved that these rays could be used for the cure of disease in a manner capable of perfect control by means of a more or less intense application for a longer or shorter period, producing reaction in the exact degree required. In this way it has been possible for the lecturer, on the one hand, to remove hair from parts of the body where it constituted a disfigurement without causing the slightest inflammation, while, on the other hand, he has been able to treat lupus with uniform success by means of an artificial inflammation, the intensity of which he was in a position to increase or reduce at will. The results secured by the new method both in the removal of superfluous hair and the treatment of lupus were demonstrated in the persons of some of Dr. Schiff's patients.

Electric Drill in Shipyards.—We illustrate below an electric drilling machine engaged on drilling the rudder frame of the Japanese battleship *Shikishima*, 14,950 tons, at the works of the Thames Ironworks and Shipbuilding Company, Limited. This illustration shows very forcibly the advantage of being able to take such a tool to the work, instead of having to take the work to fixed machine tools in the shops. We understand that the performance

of the machine in question has been very good, as by its use one man and a boy have drilled $\frac{5}{8}$th-inch tapping holes, $1\frac{1}{4}$-inch deep, in the rough cast-steel of which the rudder is composed, at the average rate of rather more than 100 per working day of eight hours. This was not on test holes, or anything of that sort, but is taken from the weekly work record sheet, the time including all shifting and setting up of the machines, grinding drills, and so on. We understand that the Thames Ironworks Company makes these drilling machines in a variety of patterns and sizes.

Obituary.—We hear with great regret of the death, under very sad circumstances, of Mr. Nelson W. Perry, who until very recently was editor of New York *Electricity*. On March 26th he was experimenting in his laboratory at Brooklyn, and when the gas was turned out he drank bichromate of potassium instead of a glass of water. He immediately called for medical and other assistance, but all efforts were of no avail, and he died the following night. Mr. Perry was extremely popular among the electrical fraternity in the States, and his name is also well known in this country, his papers read before the American Societies on various subjects having been reprinted in the press on this side. He will also be remembered as an occasional contributor to *Cassier's Magazine* and other journals. Mr. Perry was only 45 years of age, and but for the sad accident mentioned would still be continuing his researches in electrochemistry and the other branches of electrical work to which he was devoted. In his earlier days Mr. Perry practised in mining engineering, and at one time held the chair of metallurgy at the University of Cincinnati. He went into electrical engineering in 1887, and was connected with several leading electrical manufacturing companies, and in 1891 became associated with *Electricity*. He was a member of various New York and Continental scientific societies. His lengthy contribution to the National Electric Light Association in 1895 on the storage of energy essential to economy of working in central stations appeared in the ELECTRICAL REVIEW during March and April of that year.

The Late Strike.—A "Working Man" writes a long letter to *Engineering* anent the late engineers' strike, with special reference to the bearing of Sir Richard Tangye, of whose gift of £500 to each side he does not approve. He thinks Sir Richard ought to have joined the Federation and locked out the men who were unionists instead of helping to prolong the strike by supplying funds more or less directly for the unionists to hand over to Mr. Barnes. "Working Man" also recommends working men to study the past eight months' newspapers, and they will find that the labour leaders have been addressing so many meetings at *so much and their expenses*, which means that these men were reaping a golden harvest while their dupes and paymasters were walking about in idleness. He further suggests that with the £500 returned to him by the employers and the £500 which the A.S.E. ought to return to him, Sir Richard should either make a payment to his 2,500 men, or should start a fund to send a few of the more intelligent and young men to travel abroad and visit the great foreign industrial centres so as to get at facts which, if known, would go far to prevent future strikes, and so make it necessary for labour agitators to work honestly for their living. If it had not been for the Employers' Federation it might have been Sir Richard would not have had £1,000 to give away, and if his men had been unionists all his boasted friendship with them would have availed nothing if the A.S.E. had ordered the men out, for out they would have had to come or lose all accumulated benefits. "Working Man" seems to know of what he speaks, and does not much love the conduct of the A.S.E., and makes a good point of his description of the behaviour of mild-mannered deputations to employers and the braggadocio of the same deputies when speaking at unreported meetings. He concludes that neither the men, the masters, nor the country at large have gained by the strike, but only the agitators, who have reaped gold out of their fellows' idleness and starvation.

The Voltmeter on Series Arc Lighting Circuits.—In an article which appeared recently in the *Electrical Review* of New York, our contemporary draws attention to the frequent neglect of the use of voltmeters on series arc circuits in America, although its employment in such a case is quite as necessary as that of an ammeter on a constant potential circuit, since on a constant current circuit it is the voltmeter reading which measures the output of the machine at any given moment. Besides being necessary for the measurement of output, the voltmeter is a most useful addition to the testing equipment, as, by its means, the existence, locality, and approximate resistance of a fault can be indicated whilst the circuit is running. The utility of the voltmeter as a testing instrument has long been recognised by English engineers, and we know of arc lighting circuits which are regularly tested by means of an electrostatic voltmeter, which is connected between one terminal of the circuit and earth, so as to show the potential difference between that terminal and the fault, and thus indicate its position if the drop of volts per lamp is known. The electrostatic voltmeter, however, gives no indication of the fault resistance, and, further, if the potential difference between one terminal and earth is half that between the two terminals, one cannot say whether there is a fault halfway round the circuit or not, as the same reading would be obtained if the insulation were practically perfect and the small leakages which must always exist were equally divided over the circuit. This difficulty is obviated by the use of an electro-magnetic voltmeter of known resistance, and our contemporary describes one which has been brought out by the Keystone Electrical Instrument Company, and which is said to give very satisfactory results, as it is dead-beat, direct reading with a practically uniform scale from zero to the maximum reading, and is made for use on circuits up to 6,000 volts, without requiring the addition of any external multiplying resistance box. With an electrostatic voltmeter, if A is the potential difference between the positive terminal and earth, and D the drop of volts per lamp, and if there are N lamps between the positive terminal and the fault, the position of this latter is indicated by solving the equation $N = \frac{A}{D}$. With the electro-magnetic instrument it is necessary to make two other measurements, B the potential difference between the negative and earth, and C that between the positive and negative, and the value of N is then given by the equation $N = \frac{A\,C}{D\,(A + B)}$. Also if the R is the resistance of the voltmeter, and R′ that of the fault, the value of the latter is given by the formula $R' = R\,\frac{C - (A + B)}{A + B}$. It will be noticed that if R′ is very small compared to R, the sum of the two readings A + B will be very nearly equal to C, and in the extreme case when equality exists the multiplier $\frac{C}{A + B}$ being unity, the equations for the two types of voltmeter become the same.

Operation of T.-H. Arc Dynamos.—As I have never seen anything in print about caring for Thomson-Houston arc dynamos, I venture, says Mr. C. C. Giles in the *American Electrician*, to send a few suggestions about these troublesome machines. In the first place, the commutator, brushes, and brush-holders should be well cleaned after every run. Adjusting the machine with too short a spark will cause "flashing." The spark can be lengthened by turning the commutator slightly forward on the shaft. This weakens the machine, however, and if it is well loaded, care should be taken not to weaken it so much as to cause the regulator to rest on the stop. The commutator should not be moved more than $\frac{1}{16}$ inch at a time. Much trouble is sometimes caused by the air-blast being worn out. The hubs should fit snugly in their bearings in the sides of the air-blast. I have seen them with as much as $\frac{1}{16}$ inch play. The General Electric Company will repair them much more cheaply than new ones can be obtained for. I have obtained the best results by adjusting the air-jets so that the blast will strike about $\frac{1}{4}$ inch in front of the brushes when the regulator is down. Of course, if the machine has to work with a light load, this cannot be done. If the load is very light the armature will get quite hot. This can be remedied by connecting a rheostat between the binding post and connecting-rod post on the right-hand leg of the machine. This weakens the field and causes the regulator to run lower. The height at which the regulator runs can be adjusted by turning the rheostat. It should not be more than $\frac{1}{2}$ inch from the top. When the rheostat is in use, the spark will be longer than usual, and may be a little harder on the segments and brushes, but these are cheaper than armatures. The rheostat should have not less than 60 ohms resistance.

Local Authorities and Electric Lighting.—The following letter on a very important subject appeared in the *Times* the other day above the signature "Electron." The writer says :—

A list has just been published of local authorities to whom provisional orders for supply of electricity have been granted by the Board of Trade, but in respect of which no works have yet been decided upon. The list in question contains the names of no less than 83 towns, the orders being granted between the years 1890 and 1897, of which number 11 have remained in force over seven years without being dealt with. Under the Electric Lighting Act and the practice of the Board of Trade a preference is given to applications by local authorities, commercial enterprise being excluded in the desire to promote the municipalisation of electric supply. This action has given, as may be judged from the above statement, great power to the gas interest and other adverse influences among town councils, vestries, and boards of works in preventing any practical application of the Electric Light Acts. I notice that an arrangement has recently been come to between the Board of Trade and the Marylebone Vestry for granting a provisional order to the vestry in the Session of 1899, on condition that the clauses authorising a transfer of the undertaking to private firms or companies are eliminated. If this be an indication of a change of policy on the part of the Board of Trade, the abuses I have referred to will be prevented in the future, but in order to deal with the deadlock in this important industry in the 83 towns of which the names have been published, I submit that a time limit should now be fixed by the Board of Trade within which the works are to be carried out or the powers transferred to others or absolutely revoked.

This letter is followed by a more lengthy one signed by "A Burner of Electricity and Ratepayer of Marylebone," who says :—

The Vestry of Marylebone is seeking powers to compete with the existing company supplying the district. The policy of allowing vestries to use the money of the ratepayers for large commercial undertakings is doubtful in any case, but where it is to be employed to compete with an existing company for electric lighting it is especially so. If it could be shown that in a particular parish private enterprise had failed to supply an efficient light, there would be some justification in the local authority undertaking the work; but for a vestry to deliberately embark in the lighting business in order to compete with an existing company requires strong arguments for its justification. In order to do this it would have to be shown that the costly competition would ultimately benefit the consumer by cheapening his light. A little consideration will show the fallacy of this assumption. In order to supply electric light cheaply, two conditions are essential; the one is to minimise the capital expenditure, the other to keep down the working expenses. Instead of doing this, the effect of the Vestry competing would be exactly to double the capital, and nearly to double the working expenses. There would have to be erected and equipped costly generating stations, and there would have to be buried in the ground hundreds of miles of cable. The stations would be in close juxtaposition to the existing works, while the cables would have to lie side by side with the present network, the existing works and cables being already amply sufficient. Then, when all the works had been constructed, the whole of the annual working expenses, maintenance, and supervision would have to be provided for. Now, who ultimately has to pay for all this useless expenditure? Undoubtedly the consumer will have to do so! Neither a vestry, any more than a private company, can afford to sell light at less than cost price; the only way, therefore, to benefit the consumer is to decrease the cost of production. This is what is occurring in districts now supplied by first-rate companies, who find that as the number of lamps connected with their systems increase so much the more cheaply in proportion can they supply the light. This, and not competition, is the explanation of the rapid reduction in price going on. Four years ago, in the parish in which I am writing, and in which, up to the present time, there has been no competition, we paid nearly double what is now charged for the light, and believe as the company increase their business so will it be their interest still further to reduce the price. The safety to the consumer consists, not in useless and expensive competition, but in the fact that every electric company is doing its utmost to produce cheaper, so that the price charged for electric light may compete successfully with gas and mineral oil. If the present companies are only allowed to develop without ruinous competition with the vestries the time cannot be far distant when every householder will get this healthy light at as cheap a rate as he now pays for his gas or lamp.

The Production of Electricity by Chemical Means.—Up to the present it can scarcely be claimed by any inventor that he has succeeded in producing electricity by depending solely upon chemicals. There are a great many whose attention has been devoted to this branch, but the problem of economical production yet remains to be solved. Ernst Andreas (*vide Zeitschrift fur Electrochemie*, 1895, No. 3, page 188), has recently been examining Borcher's cuprous chloride carbonic oxide cell, using carbon electrodes dipping respectively into solutions of cupric chloride in water, and of cuprous chloride in aqueous hydrochloric acid. A porous diaphragm separated the two solutions, chlorine being passed into the cupric, and carbonic oxide into the cuprous solution. After a time the current rapidly diminished, and it was found that the cuprous chloride was completely oxidised. The carbonic oxide had taken no part in the change. Of 1,950 cc. used in one experiment, 10 cc. only were oxidised to carbonic anhydride. Similar results were obtained with electrodes of platinum, palladium, or nickel at various temperatures. A gas battery, consisting of two pieces of platinum gauze separated by a sheet of filter paper moistened with the solution of an electrolyte, had a very low resistance, and gave very encouraging results with coal-gas and air, oxygen and hydrogen, or chlorine and hydrogen. The last combination, with the gases under a pressure of about three atmospheres, gave a current of about 1 ampere at 1·5 volts. Owing to the cost of the platinum, such a cell could not be a commercial success; but fairly good results were obtained by passing sulphurous anhydride on the one hand and chlorine on the other, under pressure, into carbon tubes dipping into dilute sulphuric acid. This combination gave 0·5 volt, with 1 ohm resistance in circuit, and the products are sulphuric and hydrochloric acids. With large electrodes, good results would probably be obtained with air and sulphurous acid, in which case the product would be sulphuric acid alone.

The Parliamentary Electricity Committee.—The Electrical and Allied Trades Section of the London Chamber of Commerce passed the following resolutions on March 24th:—

1. That the Electrical Section of the London Chamber of Commerce is of opinion that the principle of the reference to the Joint Committee of the Houses of Lords and Commons on electrical energy (generating stations and supply) should be supported.
2. That the various municipalities and companies interested in electric lighting be asked to support the principles contained in the reference to the Joint Committee.
3. That a Committee be appointed (with power to add to their number) to take such action with regard to the inquiry of the Joint Committee as may be deemed advisable.

Relative Economy of Steam Plant in Electrical Stations.—We quote from an article by M. Van Kesteren on the "Construction of Tramway Lines for Electrical Traction," that appeared in the *Bulletin* of the Association of Electrical Engineers of the Montefiore Institute, the following table, which shows the influence of the choice of the steam plant used on the maintenance and working expenses of electrical stations:—

Mode of production of electrical energy.	Price per car kilometre.
Direct-coupled Corliss engine, of a power above 1,000 I.H.P.	·137 to ·19 francs.
High speed compound condensing engine, with belting power above 600 I.H.P. ...	·206 to ·293 „
High speed compound tandem non-condensing engine, with belting power above 400 I.H.P....	·208 to ·296 „

E. P. (*L'Electricien*).

Geneva Electrical Trust.—The *Financial News* says that there has been a good deal of talk recently about the formation of an Electrical Trust, with a capital of a million sterling, at Geneva. The project has at length assumed definite shape. The chief mover in the matter is the Union Financiere. Berlin is finding some of the capital, but London is responsible for the major portion.

NEW COMPANIES REGISTERED.

Electric Light and Power Company, Limited (56,786).—Registered April 1st, with capital £6,000 in £1 shares (5,000 deferred), to carry on the business of an electric light company and supplier of motive power, and the business of electricians, electrical, mechanical, and general engineers, electrical apparatus manufacturers, &c. The subscribers (with one share each) are:—R. S. Rose, 44, Wharncliffe Gardens, N.W., stenographer; R. F. W. Martin, Clarendon Villa, Ashford, Middlesex, electrical engineer; P. H. Drake, 19, St. George's Road, Wimbledon, clerk; A. Scott, 11, Barton Street, Westminster, builder; D. Hays, 15, Montpelier Road, Ealing, electrical engineer; S. M. Powell, St. Faith's Road, Norwood, secretary; O. S. Phillpotts, 2, St. Mary's Terrace, Paddington, clerk. Registered, without articles of association, by Markby Stewart and Co., 57, Coleman Street, E.C.

New Electricity Supply Syndicate, Limited (56,815).—Registered April 2nd, with capital £40,000 in £1 shares to adopt an agreement with A. T. Salisbury-Jones, G. L. Bidwell, and F. W. Salisbury-Jones, and to promote, construct, equip, maintain, manufacture, improve, work and manage electrical works and appliances for electrical lighting. The subscribers (with 100 shares each) are:—Lurgan, Lowndes Square, S.W., peer; F. B. Jameson, 29, Kildare Street, Dublin, distiller; J. Hone, Roebuck Grove, Donnybrook, director; J. Chambre, Mespt House, Dublin, merchant: T. B. C. Hardman, 14, Molesworth Street, Dublin, solicitor; G. E. H. Trevor, 14, Onslow Square, S.W., gentleman; A. A. Baumann, 109, Queen's Gate, S.W., barrister. The number of directors is not to be less than two nor more than seven. The first are Lord Lurgan, and A. A. Baumann; qualification, 50 shares; remuneration, £2,000 per annum divisible. Registered by F. King, 28, Park Road, Wandsworth Common.

Yarmouth (Isle of Wight) Electricity Supply Company, Limited (56,884).—Registered April 7th, with capital £5,000 in £5 shares, to carry on in Yarmouth, Isle of Wight, and elsewhere, the business of electricians, electrical and mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with one share each) are:—Heytesbury, Heytesbury, Wilts, peer; R. H. H. Eden, Heytesbury, Wilts, land agent; B. M. Aubyn, Tapnell Farm, Freshwater, Isle of Wight, land agent; F. Christy Chelmsford, electrical engineer; Mrs. C. Edmonds, The Retreat, Yarmouth, Isle of Wight; J. T. Harwood, Yarmouth, Isle of Wight, ironmonger; C. Edmonds, Yarmouth, Isle of Wight, solicitor. The number of directors is not to be less than three nor more than five; the first are Lord Heytesbury, R. H. H. Eden, C. Edmonds and B. M. St. Aubyn; qualification, two shares; remuneration, £50 per annum, divisible. Registered by Ford & Co., 6, Dowgate Hill, E.C.

J. Goodman & Co., Limited (56,886).—Registered April 7th, with capital £7,000 in £1 shares, to acquire the business of J. Goodman & Co., of 48, Commercial Street, London, and to carry on the business of electric supply merchants and dealers, electrical engineers, &c. The subscribers (with one share each) are:—J. Goodman, 11, Navarino Road, Dalston, merchant; D. J. Mihr, 7, Dempsey Street, Stepney, clerk; E. Gutmann, 17, St. Phillip's Road, Dalston, traveller; W. Musk, 30, Mount Street, Bethnal Green, E., lamp maker; W. Ashley, 76, Bird-in-Bush Road, Peckham, electric lamp maker; W. Tatum, 65, Shrubland Road, Dalston, painter; R Sendal, 21, Yotton Street, South Bromley, E., engineer. J. Goodman is the sole managing director. Remuneration as fixed by the company. Registered by H. C. Davis, 52, Allison Road, Harringay, N.

CITY NOTES.

The Indo-European Telegraph Company, Limited.

In the report for 1897 the directors express their deep regret at the loss of the valuable services of their late colleague, Mr. C. W. Earle, who died last June, and who had been connected with the company since 1881. The company's revenue from all sources for 1897 amounted to £130,347 3s. 5d., as compared with £123,539 17s. 11d. for 1896, showing an increase of £6,807 5s. 6d. The expenses were—on commercial and general account, £36,765 11s. 5d.; on maintenance account (expenses and charges) £32,613 2s.; total £69,378 13s. 5d., as against £68,105 10s. for 1896, an increase of £1,273 3s. 5d. Deducting the above expenses, taking credit for £7,704 3s. 2d. brought over from 1896, and debiting income-tax, there remains the sum of £66,573 4s. 1d. From this amount £15,000 has been placed to reserve, and that sum, together with £10,625 amount of interim dividend, have to be deducted, leaving a balance of £40,948 4s. 1d. The directors now propose the declaration of a dividend for the six months ending December 31st of 17s. 6d. per share, making, with the dividend already paid, 6 per cent., and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year, carrying forward £9,073 4s. 1d. to the credit of 1898. The balance carried forward is rather larger than usual; there are, however, several items involving an increase of expenditure that will have to be provided for in the year 1898. The lines of the company continue to work satisfactorily, and the introduction of the Wheatstone automatic apparatus has proved successful: the system is being extended. Mr. T. W. Andrews has joined the board. The following directors retire by rotation, and offer themselves for re-election:—H. H. Meier, Esq., and J. Herbert Tritton, Esq.

In case any shareholder should be unable to attend the general meeting, he is requested to fill up and return the proxy form, duly signed, so as to reach the company's office not later than 12.30 p.m. on the 18th inst.

Oldham, Ashton, and Hyde Electric Tramway Company, Limited.

The first ordinary general meeting was held last week at Donington House, Norfolk Street, Strand, Mr. Emile Garcke presiding.

The Chairman stated that they had been called together to comply with the Companies' Act, which provided that a meeting should be held within four months from the date of the company's registration. The company was registered on December 18th, and the prospectus was issued in the following month. The whole of the capital offered for subscription, consisting of 4,000 5 per cent. cumulative preference shares and 4,000 ordinary shares of £10 each, was subscribed for and allotted. They lost no time in applying for a quotation on the Manchester Stock Exchange, and they were informed that, subject to their complying with a small formality, the quotation had been granted. The progress made with the works had been satisfactory. Out of the eight miles of tramways two-and-a-half miles were already constructed, and other portions were in course of construction. They were informed by the engineers that the work throughout was satisfactory; and the borough engineers of the district were, he was informed, also satisfied with it. Several gangs were employed on the works, which, they were given to understand, would in all probability be completed in July next. The contract for the electrical portion of the work was being carried out by the British Thomson-Houston Company, and they were informed that satisfactory preparations were also being made with the view to that part of the work being carried out expeditiously. They only hoped that there would be no delay on the part of the Ashton Corporation with the completion of their part of the work, so that they might have the tramway in full working order in the early autumn. The Ashton Corporation had made an agreement with the company, under which the latter would be supplied with electrical energy. He hoped when they met early next year they would be able to report, not only that the work was completed and the line opened, but that they had been already carrying and had secured a considerable amount of the local traffic. They would by that time be in a better position to state what the volume of their traffic was, but so far, they had seen no reason whatever to modify the estimates they had formed.

Mr. Alderman T. Heginbotham, the representative on the board of the Ashton Corporation, stated that the latter were doing all that they possibly could to get the engines at work, and they were well alive to what they had to do.

No business resolution was submitted to the meeting.

British Electric Traction Company, Limited.

The ordinary general meeting was held on Thursday at Donington House, Norfolk Street, Strand, Sir Charles Rivers Wilson presiding.

In moving the adoption of the report, the Chairman said he was glad to be able to state that already, at the end of their first year's operations, they had succeeded in establishing a business of considerable magnitude, and one which they had every reason to believe would become profitable to the shareholders. The gross profits for the 14 months covered by the accounts, from the date of the formation of the company to the end of 1897, amounted to £14,422, and after deducting such of the general expenses as were chargeable to revenue account, and also the expenses incurred in connection with schemes and undertakings they had thought it well to initiate, but which, for various causes, they had afterwards dropped, there remained a profit of more than £9,800. The directors did not consider it expedient that this net profit, which represented about 3½ per cent. on the capital employed during the year, should be distributed in dividends. The extensive business they were building up required that the company should occupy a strong financial position, and, in the opinion of the board, it would be more to the interests of the shareholders that the amount in question should be carried forward to next account. Original shareholders would remember that the whole of the ordinary shares were offered for subscription at the time of the formation of the company, but they were not all subscribed for, and in order to secure a quotation on the Stock Exchange the Electric and General Investment Company, and their friends, made up the subscription to 20,000 shares, and the remaining 10,000 shares were subsequently issued at a small premium. Last month the directors made an issue of 10,000 6 per cent. cumulative preference shares of £10 each, and the strong position the company occupied enabled them to be issued at a premium of £2 10s. per share. The proceeds of such issue would come into the accounts for the current year, and he might add that it was exceedingly probable that occasion would arise during 1898 for further issues of capital. He then referred to the various items in the balance-sheet and profit and loss account. With regard to the investments, £148,179, he said that this item would always remain relatively large, as it included debentures and shares held in certain associated companies, and the more they developed their business the larger would become their investments in subsidiary and other companies. The fact that the company had received nearly £3,000 in dividends in respect of the past year, although many of the investments were not made until towards the end of 1897, was evidence that they were of a remunerative character. Having alluded to a number of the important schemes which they were developing, he said it would serve to give the shareholders some idea of the magnitude of their business when he told them that they had upwards of 50 schemes under consideration, and that the agreements and contracts they had entered into and the concessions they had either obtained or applied for covered a total mileage of electrical tramways and light railways in the United Kingdom of more than 200 miles. Moreover, it was not looking too far into the future to say that a total capital expenditure of between £2,000,000 and £3,000,000 would have to be provided. Owing to the spirit which was abroad among the larger corporations to municipalise their tramways and similar undertakings, the board had, on more than one occasion, been discouraged from initiating undertakings within particular boroughs. To a certain degree that was a matter for regret. He was of opinion, not because he was associated with this company, that work of the sort in which they were interested could be better and more usefully carried out by means of a company such as theirs than by a corporation. A municipality was only able *prima facie* to carry out operations within the limits of its own boundaries, and inasmuch as for the economical and efficient working of tramways—particularly electric tramway enterprises—it was necessary there should be communication with outlying villages and other towns, they would see at once how desirable it was that the lines should be constructed on a uniform system and be, as far as possible within the district, under a single management. One might be in favour of municipalisation of electric lighting, because that was a business which could be confined within a given borough, but undertakings like tramways or railways, which depended for their success on the efficiency with which people could be moved about from one borough to another, were surely not suitable for municipalisation. He concluded by an expression of regret at the death of the Earl of Suffolk, who, he said, was only that day fortnight at a meeting of the board, of which he had been a member since the formation of the company.

Mr. Emile Garcke (managing director) seconded the motion, which was agreed to unanimously.

An extraordinary general meeting was then held, at which resolutions were passed approving several proposed light railway orders.

Douglas Southern Electric Tramway.—The directors of the Douglas Southern Electric Tramway, Limited, report a profit for last year of £736. Out of this sum, together with the balance brought forward, a dividend of 3 per cent. on the 7 per cent. preference shares is recommended, carrying forward the balance of £265. The retiring directors, Messrs. Lowcock and Fawcus, of Manchester, decline to offer themselves for re-election.

St. James's and Pall Mall Electric Light Company.—The amount of electricity sold for the quarter ended March 25th is returned at 1,016,642 units, estimated to produce £31,180, as against 907,919 units for the same quarter of last year, which produced a net revenue of £19,898. A further reduction in the scale of charges made by the company came into force on January 1st, 1898.

Oriental Telephone and Electric Company, Limited.—The directors have resolved to recommend to the shareholders, subject to the final audit of the accounts, a further dividend of 8d. per share, free of income-tax, making, together with the interim dividend paid in October last, 5 per cent. for the year ended December 31st, 1897.

The Submarine Cables Trust.—This company announces that, on and after April 15th, the coupon due on that date will be paid in full by Messrs. Glyn, Mills & Co., of 67, Lombard Street, E.C., between the hours of 10 a.m. and 2 p.m. The coupons should be left with the bankers for examination four clear days before payment.

British Columbia Electric Railway Company.—The half-yearly interest on the 4½ per cent. debentures, and on the 6 per cent. income bonds, due 15th inst., will be paid on and after that date at the offices of Messrs. Sperling & Co., 8, Austinfriars, E.C.

Eastern Extension Telegraph Company.—Numbers are advertised of 451 debentures of £100 each, which will be paid off at par on July 1st next at Messrs. Barclay & Co., 54, Lombard Street, E.C.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending April 8th, 1898, were £2,810 9s.; corresponding period, 1897, £2,078 0s. 3d.; increase, £732 8s. 9d.

The City and South London Railway Company.—The receipts for the week ending April 10th, 1898, were £884; week ending April 11th, 1897, £1,021; decrease, £137; total receipts for half-year, 1898, £15,823; corresponding period, 1897, £15,839; decrease, £13.

The Dover Corporation Electric Tramways.—The receipts for the week ending April 2nd, 1898, £117 16s.; total receipts to April 2nd, 1898, £1,395 14s. 7d. Week ending April 9th, 1898, £119 2s. 7d.; total receipts to April 9th, 1898, £1,514 17s. 2d.

The Liverpool Overhead Railway Company.—The receipts for the week ending April 10th, 1898, amounted to £1,539; corresponding week last year, £1,353; increase, £186.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending April 8th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company Limited, were £2,581.

SOCIETY OF CIVIL ENGINEERS OF FRANCE.

Sitting of February 4th, 1898.

M. Le Roy read a paper on "Electrical Heating," and first spoke of the inconveniences of the various other modes of heating (wood, coal, gas) and then proceeded to discuss the methods used up to the present day for heating by electricity. At present, heating by electricity is effected by making the electrical energy pass through fine metallic wires, offering great resistance to the current, so that these wires become heated and by conduction transmit the heat which they give off. The heat is transmitted from the wires to the insulating material that encloses them, and then to the metal surface constituting the apparatus itself, saucepan, boiler, radiator, &c. This necessitates the burner being enclosed in the apparatus itself.

For domestic purposes, therefore, it is necessary to buy quite a fresh set of kitchen utensils and train our servants to use them. From a practical point of view, these articles are, from their very construction, subject to rapid deterioration. Repairs are expensive and very difficult.

In planning his system, M. le Roy had a double object in view.

(1) To construct simple and convenient apparatus, capable for domestic purposes of being used with the ordinary kitchen utensils; saucepans, irons, &c., so that no material changes need be made.

(2) To find out theoretically what substances possess the electrical and physical properties most suited to the development of heat, and so to determine the choice of the resistance.

Of all the substances or compounds that M. le Roy has experimented upon at Prof. Troost's laboratory at the Sorbonne, crystallised silicium or graphitoid alone seems to give the desired results.

In a note, presented by M. Troost to the Académie des Sciences* at the sitting of January 17th last, M. Le Roy gave details of the resisting properties of silicium.

The coefficient of specific resistance of crystallised silicium is 1,333 times greater than that of coal used for lighting, and 235,294 times greater than that of German silver.

* See *L'Electricien*, No. 372, p. 101.

By these researches, therefore, one of the problems set was solved.

From the point of view of practical utilisation, we might construct resistances of great section and short length capable of being introduced in derivation in quantities of 1, 2, 3 or 4 into burners similar to those of gas stoves.

M. Le Roy explained in detail the theoretical considerations that served him as a basis; he concluded from them that the choice of metal for forming a resistance to be employed for heating purposes is absolutely irrational.

He then discussed the mean relative prices of the various kinds of fuel used for heating.

If we consider the various renderings of the apparatus of utilisation, the number of calories given off by each kind of heating agent would be as follows:—

Coal	... ...	1,500,000 large calories.
Gas	for rooms	1,312 " "
	" "	525 " "
	" cooking ...	2,100 " "
Electricity	for rooms ...	864 " "
	for cooking ...	777 " "

Assuming that

The ton of coal costs	50 francs
The cubic metre of gas costs	·30 "
The kilowatt-hour costs	·25 "

The price of 1,000 large calories would be:

Coal	... ...	·033 francs
Gas	for rooms	·228 "
	" "	·550 "
	" cooking	·140 "
Electricity	for rooms	·289 "
	for cooking	·321 "

From this it follows that, leaving aside the comparison with coal, and only establishing one with gas, which is the most important point, for the heating of rooms with the most approved gas apparatus, we shall spend 100 francs where with electricity we shall spend 120 francs, and with apparatus like the block burners, electricity will come out half as dear as gas.

Cooking at an expenditure of 100 francs worth of gas will correspond to 230 francs expended on electricity.

M. Le Roy observed that the efficiencies claimed for various gas appliances assume that the mixture of gas and air necessary for combustion always takes place under the desired conditions: now, these conditions are rarely fulfilled in practice; according as the tap is more or less turned on, the proportions of the mixture vary and the efficiency is considerably lowered. With electrical apparatus the efficiency remains constant and does not depend on the skill of the operator.

M. le Roy then explained his system, on which two typical appliances, a heating stove and a little cooking stove, had been working since the commencement of the sitting.

This system consists essentially of the *electric block* which is constituted of a rod of pure silicium agglomerated and enclosed in a glass tube suitable for subjecting it to oxidation.

For the passage of the electric current this block is brought to a temperature of about 1,000°. The appliances for utilising the system can take any shape and any dimensions.—*L'Electricien.*

THE ELECTRICITY SUPPLY OF LONDON.*

By ARTHUR H. PREECE, Assoc.M.Inst.C.E.

The supply of electricity on a commercial scale had been started in London after the passing of the Act of Parliament in 1888, which amended the Act of 1882, principally by extending the date for compulsory sale to the local authority from 21 years to 42 years. In 1888 many companies applied for provisional orders, and, in determining which were to be granted powers, and the districts over which the powers were to extend, the Board of Trade decided that competition would be advantageous to the public, and that it was advisable to allow one direct current system to compete with one alternating current system.

There were now in London 11 important companies and five vestries supplying electricity, and three other companies and three vestries were taking steps to start works. The capital invested in the industry amounted to £6,000,000, and plant was installed to the extent of 80,000 H.P., the equivalent of 2,000,000 8-C.P. lamps being connected to the mains. The total annual revenue was £800,000, and the total annual expenditure, £450,000.

Of the systems for supplying electricity in London, the alternating current was applicable to large areas where consumers were scattered, and it enabled the generating works to be established by the riverside, or where land was cheap and coal was easily unloaded. The undertakings using this system were: the City of London Company, the Metropolitan Company, the London Electric Corporation, the County of London Company, the House-to-House Company, the Hampstead Vestry, the Islington Vestry, and the Hammersmith Vestry. The direct current systems were divisible into two classes, the high pressure and the low pressure. In the former rotary transformers were used to reduce the high pressure to a low pressure, while the latter produced and distributed electricity at the same pressure at which it was supplied to consumers. The direct current systems were applicable to compact areas, and, with the use of high pressure, to scattered or isolated compact areas. The chief advantages of the direct current system were the possibility of using storage batteries, which could not be employed with the alternating current systems, greater efficiency in distribution, and greater adaptibility to motive power. The undertakings using the system were: the Chelsea Company (high pressure), Charing Cross and Strand Corporation (high pressure), the Westminster Corporation, the St. James's and Pall Mall Company, the Kensington and Knightsbridge Company, the Notting Hill Company, the St. Pancras Vestry, and the Metropolitan Company (at one works).

The generating works of the several undertakings in London contained many interesting features. No less than 20 different works had been erected. The boilers used comprised the water-tube, marine, Lancashire, and miscellaneous types; but the preference for the water-tube boiler was very marked. The works were liable to sudden demands through fogs, and the quick steaming properties of this type of boiler were of great advantage. The boilers were fired chiefly by hand with Welsh coal, but in the works of the City of London Company and the County of London Company mechanical stokers and cheaper coal were used. The use of extensive systems of steam pipes was now being dispensed with. The multiplicity of valves was unnecessary, and the number of valves was being reduced, and arrangements were made as simple and with as few joints as possible.

The present tendency was towards engines of the marine type for large outputs. The high speed engine was not used for larger powers than 750 H.P. Some engineers, however, found engines of 350 H.P. sufficiently large and the most convenient unit to adopt. The dynamos were similar in most works, and were always connected direct to the engines. Storage by secondary batteries was not extensively employed in London, as their maintenance had hitherto proved expensive. But a few works used them entirely for maintaining the supply after midnight, and in the daytime in summer. The author gave the results of a test of a small marine engine and alternator, showing the combined efficiency to be 85·5 per cent. The question of vibration had been of great importance in many works; no cure had been found effective when once vibrations were set up. High-speed engines must have three cranks to be free from appreciable vibration.

The favourite methods of distributing electricity were to transmit current at a high pressure in heavily-insulated cables in iron pipes, and current at a low pressure in insulated cable in stoneware conduits, or in cables heavily armoured and laid direct in the ground. Rubber was now little used, paper and jute, impregnated with insulating compounds, having been extensively adopted.

The usual system of measurement of the electricity supplied was by meter, and the average charge was 5½d. per unit. The average charge in 1890 was 7½d., so that the price of electricity had been reduced in eight years no less than 25 per cent., equivalent to a reduction in the price of gas from 4s. to 3s. A curve was given to show the variations in the price of gas since 1870. The average price had varied between 4s. and 2s.; it was now 2s. 7d. The cost of generating and distributing electricity had been greatly reduced in the last few years. In 1892 it was seldom supplied for less than 4½d. per unit. The usual cost was now 2½d. to 3d. The actual cost of generating was about 1½d. per unit, and the cost of management, &c., about 1d. The direct current was everywhere produced at a cheaper rate than the alternating current. The difference was between ½d. and 1d. per unit, or 20 per cent. cheaper.

Since 1888 an important inquiry had been held by the Board of Trade regarding the maximum pressure permissible in consumers' premises. The result of this inquiry, in 1896, was to increase the pressure from 150 volts to 250 volts.

A comparison was made between the two largest companies in London, namely, the City of London Company, which supplied alternating current, and the Westminster Corporation, which supplied direct current. Both companies had nearly the same number of lamps connected to their systems, the number of 8-C.P. lamps connected being 270,898 and 269,939 respectively. The capital expended was respectively £945,829 and £546,434; the annual incomes per 8-C.P. lamp 11s. 9d. and 7s. 9d.; the annual expenditures per 8-C.P. lamp, 4s. and 3s.; and the costs per unit, 7·6d. and 5·8d.

The industry was growing so rapidly, that most undertakings had to seek new sites for generating works, and the tendency was to erect large works on the outskirts of London, where coal could be conveniently brought to the site, and where water could be obtained for condensing. The powers granted under provisional orders were limited as regards the compulsory purchase of land, and further powers were being sought by some companies from Parliament, so that they might be placed on the same footing as railway companies. No less than 40,000 H.P. was now being installed in London in order to meet the demand for electricity in the immediate future.

SOME RECENT IMPROVEMENTS IN ACCUMULATORS AND THEIR APPLICATION TO TRACTION ON COMMON ROADS.*

By J. T. NIBLETT.

(*Continued from page* 491.)

A material for making the elements of secondary batteries quite distinct from any of those already considered is known as lithanode. The credit of devising lithanode is doubtless due to Mr. Desmond FitzGerald, whose labour in the field of electro-chemistry is well known. Batteries, with improvements made on Mr. FitzGerald's original invention, are now made by the Lithanode Electric Storage Company.

Lithanode is not compressed peroxide of lead, as is sometimes supposed, for, however strongly this lead peroxide may be compressed, the resulting mass will disintegrate when immersed in a liquid electrolyte. It is produced from litharge made into a pasty mass with a solution of sulphate of ammonia, which causes the material to "set," so that it will no longer disintegrate when placed in a fluid. The "forming," according to the original idea, was performed in a bath of sulphate of magnesia. In ordinary practice the elements are made up of a number of small slabs of lithanode, whose outer edges are V-shaped. These slabs or pellets are arranged in a casting mould of any suitable dimensions, and are placed at such a distance apart and from the edges of the casting frame as to allow of sufficient space for the requisite quantity of metal to run in and impart adequate mechanical strength to the completed element. After the pellets have been arranged in this manner, an alloy of lead and antimony is run into the interstices, and thus a complete plate is formed.

Before being cast up the positive pellets are converted into peroxide of lead in a forming bath; those for the negative plate are simply dried and cast up direct, the lithanode in the latter case being reduced to a condition of spongy lead by the ordinary electrolytic method.

Where lightness is a desideratum, as in the case of a traction cell, the pellets in the positive plates are made larger, while the negative plate is constructed of lead gauze, having its outer edge strengthened by a rim of lead. The gauze is filled in with the prepared litharge which entangles itself in the thin lead wire, and thus produces a plate of great lightness, and one little liable to fall to pieces.

Lithanode may be obtained in varying degrees of porosity. For high discharges it is made of a highly porous nature, the porosity being produced by incorporating in the material cystals of some salt, which is practically inert, and which is dissolved out during the forming operation.

The rate of discharge obtainable from lithanode batteries varies

* Abstract of paper read before the Self-Propelled Traffic Association, Liverpool Centre, on March 29th.

between very wide limits, and is regulated by the character of the lithanode, whether made hard, medium, or soft. The ordinary working rate of discharge is $\frac{1}{14}$th of an ampere per square inch of lithanode plate, but owing to recent improvements very much higher rates of discharge can be obtained.

The electrical capacity of lithanode, when discharged at the above rate, is almost exactly one ampere-hour per ounce, so that in a lithanode element weighing 1 lb. a current capacity of 16 ampere-hours is obtained. In practice, however, this high capacity is never reached.

Thinking it may be of interest I have prepared the following particulars taken from one of the company's most popular types of portable battery:—

DATA OF COMPLETE 30 AMPERE-HOUR LITHANODE BATTERIES, INCLUDING WOOD CASES.

No. of cells.	Outside dimensions of battery.			Open E.M.F. of battery.	Approximate gross weight of battery.
	Length.	Width.	Height.		
	inches.	inches.	inches.	volts.	lbs.
1	3·75	7 00	6·37	2	8¼
2	5 12	7·00	6·37	4	16
3	7 27	7·37	7·00	6	22¼
4	9 50	7·37	7 00	8	29
5	11·60	7 37	7 00	10	36
6	13 75	7·37	7 00	12	43
7	15 78	7 37	7·00	14	50
8	18·00	7·37	7 00	16	56¾
9	20·12	7·37	7 00	18	63¾
10	22·24	7·37	7 00	20	70¾
11	24·36	7 37	7 00	22	77¾
12	26·50	7·37	7 00	24	84½

DETAILED PARTICULARS OF CELL.

Vulcanite containing cell	6·25 inches long. 2·12 „ wide. 5·25 „ high. weight, 10 ozs.	
Positive element ...	Two plates in each cell,	5·9 inches long. 3 9 „ wide. 0·25 inch thick. weight, 1 lb. 1½ ozs.
Negative elements...	Three plates in each cell,	5 9 inches long. 3·9 „ wide. 0·13 inch thick. weight, 11½ ozs.

Weight of connectors, 3 ozs.
Weight of cover, vent plug, sealing, and separators, 2 ozs.
Quantity of electrolyte, 15·5 fluid ozs.
Gross weight of complete cell, 6 lbs. 7 ozs.
Normal charging rate, 3 amperes.
Normal discharging rate, 3 to 4 amperes.
Maximum safe discharging rate, 9 to 12 amperes.
Approximate internal resistance, 0·015 ohm.

The data given will give a fair idea of what is obtained in actual working with this form of cell. Other batteries of larger capacity are, of course, made, and as the capacity increases, the proportional weight and bulk slightly decreases. These batteries have been used extensively for lighting vehicles, actuating coils for X ray photography, and for propelling electric launches and light forms of motor-cars.

The Chloride Electrical Storage Syndicate make their accumulator plates on a somewhat similar plan to that adopted by the Lithanode Company. In this case, however, instead of using litharge, chloride of lead is employed to make the pellets.

Chloride cells are well known and largely used for traction purposes in America, and they are very well received in this country also.

A form of cell which is just now exciting much attention on the Continent is known as the "Marschner" cell. The Marschner battery is at present being used on the Dresden tramways, and it is said to be behaving in a very satisfactory manner. The plates are stated to consist of the ordinary oxides of lead, incorporated with powdered amber and an essential oil. This mixture is said to "set" very hard, the resultant plate being of a tough metal-like nature. On the Dresden car 144 cells of this type are being used. Each cell contains 13 plates, and is said to weigh only about 28 lbs. The weight of the complete battery is given as 5,290 lbs. Its efficiency is stated to be over 90 per cent., and if discharged at its normal rate—that is, 65 amperes—an energy capacity of 13 watt-hours per pound of cell is obtained.

When devising cells for traction purposes many difficulties have to be overcome. Owing to their high initial cost, a small number of cells should be made to suffice, and these should be so constructed that they will run a vehicle for a reasonable number of hours with one charge. They should be capable of being charged and discharged at rapid rates. Above all, they should be able to withstand the jolting and jarring incidental to their being run over rough and uneven roads. The cell should be so constructed that the wash of the electrolyte does not remove the active material.

There is at the present moment an enormous field for an inexpensive cell which will combine large capacity with small weight and great solidity. Some form of mechanically solid cell seems to offer the best solution for this problem. Some little time ago great hopes were entertained that the solidity problem had been solved by the introduction of Dr. Schoop's solid electrolyte. This so-called solid electrolyte was made by adding silicate of soda to the ordinary solution, which caused it to set and become of a gelatinous nature. In this country some practical tests have been made with Mr. Barber-Starkey's method of making solid cells by substituting for the electrolyte a mixture of wood sawdust and plaster of Paris, which when set was moistened with dilute sulphuric acid.

The accumulator known in America as the "Hatch" is of a mechanically solid nature. In this case metallic frames are not employed for supporting the lead salts, as they are held within a porous earthenware grid serrated on one side, and, having small square recesses on the other. Plain lead plates are used as conductors, and these are bedded on the moist lead salts. According to this arrangement there is no clear liquid space between the elements, as the serrated earthenware plates touch one another, and are so placed that the ridges on one plate are placed at right angles to those on the other. Wooden clamping plates with India-rubber bands placed around them are fixed on the outside of each end element, and these serve to give the requisite elasticity. The "Pumpelly" cell is another American production, and in this case the mechanical solidity of the cell is arrived at by inserting plain, thick, porous earthenware plates between the elements. In this case, however, the plates are placed horizontally instead of vertically as in the "Hatch."

One great drawback to the employment of a viscous, gelatinous, or semi-solid electrolyte arises from the fact that when such substances are interposed between the plates no free circulation of the liquid is possible. In all secondary batteries, as already shown, the activity of the elements depends entirely upon chemical action, and as the electrolyte is a medium through which all these reactions occur, it seems highly probable that anything which prevents its free access to the active material, or in any way impedes its circulation, must be detrimental, and consequently lead to loss of efficiency and capacity.

Some few years ago, having in view the advantages likely to be derived from the employment of a mechanically solid cell, for traction purposes, the author gave some attention to this particular form of battery, and a number of cells were constructed having this object in view. In most cases the elemente consisted of a highly cellular mass of active material which was capable of absorbing a sufficient quantity of electrolyte for the due performance of all the necessary chemical actions. Between each mass of active material was inserted a thin, highly porous, inert diaphragm, which was not found to materially increase the internal resistance, and served to complete the solid character of the cell. A large number of different combinations with various kinds of active material were tried. Owing to the cellular nature of these elements the liquid contained in the mass continually circulated, the slight evolution of gas which occurred during both the charging and discharging operations being quite sufficient to affect this. The active material was in all cases so placed that it could not be dislodged. It was found that the cellular character of the electrodes gave them a peculiar power of regulating their own internal resistance: for if the cell was being charged at too high a rate, or when it was on the point of being fully charged, the gas generated tended to drive the liquid out of the pores of the electrodes and remained imprisoned therein, thereby greatly increasing the resistance and stopping the flow of current. On the discharge, the occluded gas appeared to re-enter into the chemical combination and allow the liquid to refill the pores, thereby exposing more active surface. Little or no commercial use was made of this plan of construction, as at the time the author's attention was diverted into other channels, and the matter was dropped.

(To be continued.)

REVIEWS.

The Engineers' Year-Book, 1898. By H. R. KEMPE, A.M.I.C.E. London: Crosby, Lockwood & Co., 1898.

This valuable office book of reference has reached its fifth year, and has fairly kept to its original intention—that of keeping with the times—the various formulæ and descriptions being overhauled from year to year, so as to keep the book up-to-date.

In this year's section new matter has been added to the Earthwork Tables, and to that of Railways in respect of "Crossings," and the abstract of the Board of Trade regulations, which have been carried out by Mr. C. Seymour, of the Midland Great Western of Ireland. Information on gas engines has been supplied by Mr. H. Scholey, the section being entirely re-written. It is now in better form than before, but may still be desirably extended by illustrations and descriptions of other gas producers, and, we think, fuller reference might be made to the Thwaite system of blast furnace gas utilisation, a system which is bound to come to the front. Numerous other additions have been made, and the book contains 850 illustrations and nearly 700 pages of letterpress and index. We are inclined to think that much space might be saved by reducing some of the tables to smaller print. For example, there is a very extended table of specific gravities. It might be reduced by two pages, or even more, if many of the articles were taken out of it. This table is very full, but the equally important table of specific heats is paltry in the extreme. We required to use this, and failed to find the specific heat of glycerine, but we could find the specific gravity of juniper wood. We never knew of anyone who ever needed to know this. Juniper berries are used to flavour gin, but of what special use is the wood? Further additions might be made in the notes on water softening, which are very scanty.

We should like also to see a little fuller information on fuels. We find no statement of the calorific capacity in B.T.U. of any fuels solid or gaseous, but only of liquid fuels. More might now be given as to liquid fuels, say, an illustration of one or two examples of liquid fuel application to boilers, rivet furnaces, &c. Who knows, for example, that when using liquid fuel, it will not be practicable to mix tar with petroleum with any idea of thinning the mixture and increasing its fluidity. The petroleum will simply draw out the more liquid portion of the tar and send the pitch to the bottom to the choking of valves and pipes.

There is no information on coke ovens or residuals recovery plant—both of some engineering importance. The *fan* section might be extended and so also the pump section, two special varieties of which we see are omitted—the Hamilton and the Poblè. We note an error in the formula for radial axle boxes. The expression to the right of the = should have a denominator 2, the true formula being—

$$x = \left[\frac{(a + b) - \dfrac{a^2}{a + b}}{2}\right]$$

Makers of radial axle box vehicles have been lax in their proportioning, and this accounts for the bad running and unpopularity of radial boxes. The formula is due to Mr. Baldry who was once in the office of Sir John Fowler and, we believe, worked out the proportion of the radius bar for the eight-wheeled passenger carriages sent out under Sir John—then Mr.—Fowler's directions to New South Wales.

In sewage treatment there should be something given on the new system of bacteriological treatment which appears likely, as far as present indications point, to prove successful.

In pointing out these items, we would not imply that we look on their omission as serious, but they are items which may well be included in the next edition.

Magnets and Electric Currents. By J. A. FLEMING, M.A., D.Sc., F.R.S. London: E. & F. N. Spon, Limited, 1898.

This is described as "an elementary treatise for the use of electrical artisans and science teachers." The scientific knowledge of the reader is assumed to be practically *nil*, and the subject is taken up from the very beginning.

"Electrical artisans" of average intelligence who have scientific tendencies will undoubtedly find much to interest them in the author's admirable and lucid descriptions of how to make various pieces of electrical apparatus, from the simplest primary battery to the most perfect reflecting galvanometer, with things found about the house; and if they will only put such pieces of apparatus to the uses for which they are intended, and at the same time devote their attention to some of the less fascinating passages in the book, they will most certainly tend to become more useful members of the electrical community.

With regard to science teachers, these are of various kinds. Dr. Fleming is probably addressing himself to those whose teachings are intended to be of use to the electrical artisan, and not to the more familiar class of teachers whose teachings produce teachers.

From the reviewer's point of view, the preface is one of the most interesting portions of this substantial volume of 400 pages, because it gives him some assistance in discovering the lines upon which the author's mind has been working.

Dr. Fleming is a staunch supporter of Mr. Heaviside in his determined endeavours to eliminate, at all costs, the noxious multiplier 4 π from a large number of magnetic formulæ. He is also passionately fond of words, apparently for their own sake, and he cannot resist the temptation of giving names to things, even to mere ratios and multipliers, quite apart from the question as to whether these latter have a physical meaning or not.

We all use the word "voltage"; it is a word which was wanted, and for this reason it came—quite of its own accord; it was never invented. But Dr. Fleming now suggests *voltivity* for "voltage per centimetre." *Amperage* is also a word he enjoys writing, and when he gets to *gaussage* and *gaussivity* he is really happy. All this we can stand, within limits; but when he suggests *fluxage*, we think he is going a step too far. "Flux" was good enough for us in *our* young days, and the word is only a makeshift in any case. Then there is *coercivity*, which is not wanted, and *retentivity*, about which there is something aggressive which annoys us.

We do not say of a dinner plate that it possesses a property called greasic retentivity or greasivity, simply because, when insufficiently washed, it may retain traces of the food which has been placed upon it: there is, perhaps, no valid reason why we should not use such expressions; but, on the other hand, there is no necessity for them; and although it is well for the electrical artisan to know what is meant by residual magnetisation, he does not require to be told that it is the result of a certain quality of the iron called magnetic retentivity.

There are many other expressions which the electrician of the old school will assimilate with difficulty: thus, on page 127, is a table giving the "resistivity" of metals in "microhms per cubic centimetre," which is equivalent to what we have known for many years as the specific resistance in microhms per centimetre cube.

Returning to the preface, the author, after introducing a host of new names, remarks with reference to Faraday's beautiful conception of "lines" or "tubes" of force (which has never failed as yet), that the practical student would benefit by discarding such notions, and thinking only of a "physical state existing in a magnetic circuit, which is measured in webers and microwebers," the active cause of which is called *gaussage*, and the thing itself *fluxage*. Is he sure of this, or is it not possible that he may be mistaken, and that the practical student, of all people, is the one to whom it is essential that he should be allowed to *picture* in his mind these same magnetic lines or tubes, which have to be *cut* by a conductor in order that the latter may have an E.M F. generated in it? It is to be feared that, however much the said practical student may *think* of a physical state (called *fluxage*), this will not lead him to great things unless he be a born mathematician.

Dr. Fleming is to be congratulated upon having abandoned much that is old-fashioned in his treatment of the subject of magnetism; the strength of field is, however, still occasionally considered in relation to the tendency which would be experienced by a free magnetic pole (if let loose) to travel down it; and there are references to the demagnetising forces exerted by the poles of a magnet, which do not fit in well with the more modern conceptions of the magnetic circuit.

The last few pages of Chapter III. deal with Mr. Heaviside and the "disfiguring" 4 π. A list of Mr. Heaviside's suggested units expressed in terms of the present C.G.S. units is given, and the advantages of the new system (which are undoubtedly well worthy of consideration) are pointed out; but it is to be feared that the average Englishman will resist any attempt to change his present electrical units, for the same reasons which induce him to resent the mere suggestion of altering his delightful system of weights and measures.

In Chapter II. the author generalises on the subjects of matter and energy, space, time, and force, and describes the C.G.S. and other systems of units; and in Chapter V. he takes up a certain amount of more or less valuable space by giving us the legal definition of the ohm, ampere and volt, accompanied by all the customary rigmarole, beginning "Whereas," and ending with Her Majesty's expressions of pleasure in approving the "several denominations of standards set forth in the schedule hereto appended." Chapter VI. deals with electro-magnetic induction, and Chapter VII. is devoted to electro-magnets. The relation between the directions of the magnetic flux and induced E.M.F. is stated in various ways, but not always successfully. For instance, the "practical" student who is told to thrust his arm through an imaginary ring and give it a *positive* twist by rotating his hand in a *counter*-clockwise direction, may be expected to smile, and refuse to do it.

What is meant by mutual induction, or mutual inductance as Dr. Fleming calls it, is not made sufficiently clear. What the student generally does not understand is, where the *mutuality* comes in, and this is not explained.

In Chapter VIII., which deals with alternating currents, the much abused word "inductance" plays an important part. Dr. Fleming uses it to denote (as is customary nowadays) the quantity which is better known as the coefficient of self-induction; but it is a word with a considerable amount of latitude, and as used in many instances it would appear to be synonymous with what, towards the end of the chapter, is called the *reactance*.

Consulting engineers should read the section on transformers with the utmost caution, in order that they may not come upon the following sentence too suddenly:—"The transformer must have cooling surface enough to dissipate all the core losses without rising above the temperature of boiling water." They will do well to give this idea time to soak in, and who knows but what some of them may, in the future, have the sense to leave questions of temperature rise to the manufacturer. It is true that Dr. Fleming appears to have been carried away by a slight excess of common sense; but he shows a total and fearless disregard of public opinion which is highly commendable.

The last two chapters deal respectively with electric measuring instruments and the generation of electric currents. On page 295 is a table giving the safe working currents which may be carried by Hadfield's *resista* wire, and on the following page, a similar table for German silver wire. The temperature of the wires is, in each case, supposed to be such as "can be easily borne by the hand." It is, therefore, interesting to note that, in some of the smaller sizes, the safe current for the *resista* wire is three times as great as that given for German silver; and as the conductivity of the latter metal is four times as great as that of resista metal, it follows that, for the same amount of cooling surface, and approximately the same temperature rise, the watts lost in the one case will be 36 times greater than in the other.

Having picked out, and sufficiently magnified a few of the weak points in this book, it is only fair to add that, as a whole, it has much to recommend it. The author has done his best to treat each subject in as clear and simple a manner as possible, and he is to be congratulated upon the admirable way in which he has accomplished an exceedingly difficult task.

PERIODIC CURRENTS.

By W. G. RHODES, M.Sc.

THE tendency of late years has been to forsake the old methods of conducting alternating current calculations and to reduce the difficulties to the physical conceptions of the various phenomena. Formerly, no student not well equipped with a first rate mathematical training could hope to read intelligently the then existing literature on this subject. It was not until the application of graphical methods by Mr. Blakesley that alternating currents came at all within the scope of the ordinary electrical reader. Many writers followed suit, and nearly all writings teemed with diagrams, very interesting and useful to readers, but apparently demanding an altogether outrageous expenditure of mental energy on the part of the original writer. Who can look at the writings of Bedell and Crehore, Blondell and others, without being struck with the idea that the graphical representations of the currents and E.M.Fs., their magnitudes and phase relationships in multiple circuits and combination of circuits, must have required an altogether exorbitant amount of mental effort? That this feeling is becoming universal is evident from the fact that nearly all the prominent writers on alternating currents now use methods which, while of an analytical nature themselves, are easily capable of graphical interpretation and representation. All these methods depend upon the fact that the electrical quantities considered are capable of being represented by lines drawn of suitable lengths and along proper directions relative to each other, and upon the ability to represent algebraically directions of lines relative to one another by the help of the imaginary $\sqrt{-1}$.

Steinmetz, with the method of the complex variable, has materially advanced our knowledge of induction machines, and has carried the subject probably further than would be possible with the aid of graphics alone.

M. Vaschy has recently noticed that on the assumption that alternating electromotive forces and currents can be represented by simple sine functions of the time, if e is any such periodic function, then $\frac{d\,e}{d\,t}$ may be replaced by its geometrical equivalent, $p\,e\,\sqrt{-1}$, where $p = 2\,\pi\,n$, and n is the frequency of the function in question.

In the *Annales Télégraphiques* for November—December, 1897, M. Pomey draws attention to the writings of Vaschy, and shows how, for instance, the transformer equations

$$\left.\begin{aligned} L_1 \frac{d\,i_1}{d\,t} + M \frac{d\,i_2}{d\,t} + r_1\,i_1 &= e \sin p\,t \\ L_2 \frac{d\,i_2}{d\,t} + M \frac{d\,i_1}{d\,t} + r_2\,i_2 &= 0. \end{aligned}\right\} \quad (1)$$

where L_1, L_2 are coefficients of self-induction; M, that of mutual induction; r_1, r_2, resistances; i_1, i_2, currents; and $e \sin p\,t$, the applied E.M.F. are geometrically equivalent to the equations

$$\left.\begin{aligned} p\,L_1\,i_1\,\sqrt{-1} + p\,M\,i_2\,\sqrt{-1} + r_1\,i_1 &= e \\ p\,L_2\,i_2\,\sqrt{-1} + p\,M\,i_1\,\sqrt{-1} + r_1\,i_2 &= 0. \end{aligned}\right\} \quad (2)$$

It should, however, be particularly noted that equations (1) are more general than equations (2). The complete solution of (1) gives the values of the currents for all time subsequent to the *instant of closing the primary circuit*, whereas from equations (1) only the steady values of the currents can be obtained. Further, equations (1) are perfectly general whatever be the nature of the applied E.M.F., but for equations (2) to hold good both the applied E.M.F. and the currents must be capable of representation as a simple sine function of the time.

The writer has recently shown in a short series of articles* the application of a method leading to equations of a type similar to (2), which is essentially a vector equation of E.M.Fs. It is further demonstrated that vector equations can only exist between E.M.Fs. so as to form a vector E.M.F. equation, or between currents forming a vector current equation. It is seen that by the combined aid of analysis and graphics, problems which are otherwise formidable are solved with ease, and the analysis itself only demands quite an elementary mathematical knowledge. It is of great value that any step in the process should be capable of being readily represented in a graphical form, thus enabling a better physical conception of the problem to be obtained.

It is with no hesitation that I say that vector algebra, or allied processes, must eventually—and that before long—form the basis of calculation for all *useful* text books on alternating current phenomena, and that it is to the application of these methods we must chiefly look for further advances in the theory of the subject.

THE TRAMWAYS INSTITUTE.

THE end of March or the beginning of April might fairly be considered rather a late period at which to issue a publication bearing date of *January*, and on receipt of the *Tramways Institute Journal* the other day, we could not quite understand the belatedness of the copy sent us, except on the supposition that copies are sent out in a leisurely fashion.

The January issue, however, contains plenty of February news, so that the Institute, and its officials responsible for the journal, are not quite so out of date as would appear on the surface.

When the tramway interests of this country are strong enough, or rich enough, or united enough to support a

* "The Application of Vector Algebra to Alternating Currents," by W. G. Rhodes, M.Sc., ELECTRICAL REVIEW, January 7th, 14th, and 21st, 1898.

flourishing Institute, with an editor on the premises, this journal (if it survive so long) may then, perhaps, serve as a suitable record of proceedings; but in its present form it hardly justifies any existence at all, in view of the excellent appearance given by the electrical and railway journals that make a special feature of tramways and things appertaining thereto.

The advertisement pages of this journal afford very interesting and instructive matter for thought. Varnishes, metal for bearings, tramcars, tickets, ticket punches, rails and paving materials—all these are in order, and will probably be required even when *all* our lines are worked by electricity; but what is to be said in this present year of grace of advertisements in a tramway publication dealing with the advantages of antiseptic ointment and other medicines for horses, patent steel whipple trees, fodder of all kinds, chaff cutters and similar machines, harness, and horse rugs?

We should have thought that the benefits of advertising such materials in a *tramway* paper would not be very excessive, so far as future orders are concerned.

True, we find a few counteracting notices of electric tramway contractors and manufacturers of plant: but they don't wear a happy look in such company. The whole publication, in regard to advertisements, has the appearance of the American street railway journals of many years ago.

Turning to the inside pages, the electric car has there a field all to itself; the horse is ignored, and cables only mentioned once or twice.

Although, as stated, some of the items in the letterpress are rather more recent than the date on the outside cover would appear to convey, yet we cannot say very much for the contents. It is, and must be, extremely difficult to give *news* in a publication that appears once a quarter or so, and then three months behind time; but on the other hand, a complete summary of the quarter's proceedings—which alone would otherwise be worth consideration—would entail great labour on the part of an editor (who should have special knowledge and experience), whilst the resulting publication to be of service, would have a much greater bulk than that now before us.

However, we would not wish to detract from any efforts to encourage electric traction, and therefore welcome the evident desire of the Tramways Institute to deal more with this subject than in time past has been the case.

THE PREPARATION OF COPPER SAMPLES FOR CONDUCTIVITY TESTS.*

By Dr. S. SHELDON, Polytechnic Inst., Brooklyn.

WHILE the electrical fraternity is interested with the subject of standardisation of electrical apparatus I should like to call attention to the necessity of adopting a standard condition of softness for samples of copper whose conductivity is to be tested. Of course, users of copper wire are interested in the conductivity of the wire in the condition in which it is furnished to them—not in the conductivity which might have been given to the wire, if it had been treated differently. While the copper losses in most electrical machinery are but a small percentage of the output, and while the temperature at which the machinery will operate is uncertain, owing to the uncertainty of the factors entering into the heat escape, still in many cases a reduction of the copper losses by a few per cent. is worth struggling after. The determination of the conductivity of wire used for such purposes is an easy matter. On the other hand, the requirement of a definite conductivity, frequently found in specifications for construction work, where rubber-covered or similar wire is to be employed, gives no opportunity for the verification of the fact that the requirements of the specifications have been complied with. It is impossible to determine the cross section of the wire and the value given by the manufacturer must be accepted. Again, the tinning of the wire makes the resistance measurement valueless. These difficulties are met in some cases by the purchasers sending inspectors to the factories to determine the conductivity before the wire is covered. This is, perhaps, the best solution of the problem under the circumstances, and, according to Abbott, is the practice in American aerial line construction. To electrolytic copper refiners and all buyers and sellers of bulk copper for electrical purposes, a standard method of treatment of test samples is of utmost importance. Cases have been known where copper, contracted for future delivery at a certain price, has been rejected at the time of delivery because of too low a conductivity, the ruling price at the time of delivery being less than at the time of making the contract.

The American Institute of Electrical Engineers has adopted as its standard of conductivity for copper the value given by Matthiessen for soft copper. This is contrary to the original advice of the Committee on a Standard Wiring Table, and resulted from statements made in the discussion of the report that there were many degrees of hardness, implying that a soft condition was easily obtainable, and could be reproduced. To ascertain whether this were true or not, I had two students of last year's class at the Institute, Messrs. Alfred Muller and Herman Wallatt, investigate the influence of softness upon the conductivity. A sample of wire was passed several times through holes in a drawplate in such a manner as to yield a very hard wire. This wire was cut up into separate lengths. The assumption was made that the resistivities of these lengths were equal. The lengths were then separately subjected to different annealing temperatures for a fixed interval of time, the sample, in one set of experiments, being placed in a vacuum, and, in another set, in hydrogen. The different temperatures were produced by sending different currents through the samples. The temperatures were calculated from current measurements and measurements of voltage between separate potential terminals on the samples, Kennelly's temperature coefficient being assumed as correct. After treatment, the conductivities of the samples were calculated from measurements of resistance, length, weight, and specific gravity. The results obtained for samples annealed in a vacuum are given in the following table:—

Number of sample.	Annealing temperature.	Per cent. conductivity.
1	20°	101·5
2	37°	101·5
3	54°	101·5
4	118°	101·6
5	215°	102·0
6	300°	102·1
7	600°	102·4
8	755°	102·7
9	930°	99·0

The results for samples which were annealed in hydrogen are given in the following table:—

Number of sample.	Annealing temperature.	Per cent. conductivity.
10	20°	99·0
11	45°	99·0
12	105°	99·3
13	234°	99·8
14	360°	101·0
15	483°	101·9
16	1,050°	89·3

One end of sample 16 melted after annealing current had been flowing for about a minute. A sufficiently long wire remained for the conductivity test. This sample was very soft, and had lost much of its tensile strength.

These results show that annealing to a softness, which shall give a maximum conductivity, must take place at a high temperature regulated within rather narrow limits. The maximum mechanical softness would be obtained if the sample were melted, and, after being cast in a graphite mould, were allowed to cool off slowly. Very smooth filiform samples can be obtained in this manner. But the conductivity of copper is so dependent on the amount of sub-oxide of copper which is present in it, and this amount is altered to such an extent by melting, that the conductivity determinations on such samples give no indications of the electrical properties of the original samples. As has been recently stated by Swan, the electrical conductivity of electrolytic

* New York *Electrical Engineer*.

copper is reduced by more than 1 per cent. by melting and casting into the form of wire bars. It would, therefore, appear to be better to subject all samples to the hard drawing process. Conductivity tests would then properly indicate the original electrical quality of the copper.

COMPARATIVE COST OF STEAM AND ELECTRIC POWER.

IV.

In continuation of Mr. Taylor's articles, the water and fuel costs are elaborately tabulated, the steam consumption being found by Prof. R. C. Carpenter's method. We need not repeat the voluminous figures for the different cases, but merely summarise the results under the head of total cost for each case of 10, 25, 50, and 100 H.P., with coal at 8s. and 16s. per ton.

Coal at 8s.

—	10 H.P.	25 H.P.	50 H.P.	100 H.P.
Case I.	d	d.	d.	d.
Cost per H.P.-hour. Coal at 8s.	2·16	1·5	1·07	1·4
Coal at 16s.	2·46	1·73	1·27	1·07
Case II.				
Coal at 8s.	4·09	2·67	1·93	1·45
Coal at 16s.	4·59	3·05	2·24	1·70
Case III.				
Coal at 8s.	10	6·36	4·52	3·29
Coal at 16s.	11·02	7·14	5·11	3·78

Considering now the cost of electric power, the point of comparison is made at the point of delivery of brake horse-power.

The same elaboration of detail is gone through, which we cannot follow; sufficient that the results are given as below:—

H.P. of plant.	Description.	Cost of power. Pence per B.H.P. hour.		
		Load factor 1.	Load factor ·46.	Load factor ·18.
10	Electric motors ...	1·95	3·45	5·01
	Engines, coal at 16s.	2·46	4·59	11·02
	" " 8s.	2·16	4·19	10·0
25	Electric motors ...	1·79	2·03	3·99
	Engines, coal at 16s.	1·74	3·05	7·14
	" " 8s.	1·50	2·66	6·36
50	Electric motors ...	1·73	1·93	2·48
	Engines, coal at 16s.	1·27	2·23	5·11
	" " 8s.	1·07	1·93	4·52
100	Electric motors ...	1·70	1·69	2·44
	Engines, coal at 16s.	1·07	1·70	3·78
	" " 8s.	1·40	1·45	3·29

We give the above for what they are worth: the author has spent an enormous amount of labour on his calculations. The difficulty of all such estimates comes in with other items apart from the power plant in use. We think it difficult to work out the matter as Mr. Taylor has attempted. Yet, an experienced engineer, with little electrical knowledge, would walk through a works, note the general appointment of the power plant and of the existing modes of transmission, and make a shrewd guess at the desirableness, or otherwise, of changing the motive power. The actual question will very frequently lie between the inside manufacture of electricity and its transmission through the works and its purchase from outside supply companies.

Too frequently it will be a question as to the particular supply company one may be on. The calculations for the City of London Company, or for the County of London Company, to take two extreme cases, would obviously show an enormous difference.

NEW METHOD OF MEASURING THE INTENSITY OF MAGNETIC FIELDS.*

By E. BOUTY.

I have recourse to the induction, reciprocal of that employed by M. Lippmann in his mercurial galvanometer. A liquid conductor, which may be simply river water, flows at right angles to the field to be measured. The constant electromotive force induced between two opposite faces of the stream is determined by means of a capillary electrometer; whence, knowing the flow, we can deduce the intensity of the field. To take a simple case, suppose the velocity of the flow, v, to be uniform over the whole section of a rectangular stream of depth, e, measured in the direction of the lines of force, and of width, l, measured in a direction perpendicular both to the lines of force, and to the stream. The induced electromotive force is constant, and has a value E,

where $$\mathrm{E} = \mathrm{H}\, v\, l. \quad (1)$$

The flow is $$\mathrm{D} = v\, e\, l. \quad (2)$$

Whence $$\mathrm{H} = \frac{\mathrm{E}\, e}{\mathrm{D}}. \quad (3)$$

We have to apply this very simple formula.

Equation (1) shows that the induced electromotive force is independent of the nature of the liquid conductor. I employed at first solutions of sulphate of copper, both saturated and very dilute, flowing through a rectangular conduit or tube of ebonite. Two electrodes of copper ·01 metre long, and of a width, e, exactly occupy the side surfaces of the tube between the back and front faces of the stream. Having ascertained that the electromotive force measured is perfectly independent of the concentration of the solution, I was able, without making any other change, to substitute water from a tap for the sulphate of copper: the facility of making measurements remaining the same. Polarisation of the electrodes introduces no disturbance.

Using water as the liquid conductor, high velocities of flow can be employed, and the sensitiveness of the method indefinitely increased.† With velocities varying from ·5 metre to 17 metres per second, I have proved that the electromotive force is exactly proportional to the speed, and have detected fields of the order ·5 C.G.S. unit. I see no reason to think that I have reached the limit of possible sensitiveness.

For comparative measurements neither the depth, e, of the tube nor the rate of flow, if it be kept constant, need be measured, and the tube may have any convenient form; but perfect insulation of the electrodes is absolutely necessary. For absolute measurements, a standard tube must be procured in which e is of such a size that the value of v may be treated as sensibly uniform over its sectional area, as we have supposed to be the case in the equations.

The copper electrodes of width, e, the depth of the tube, must be inserted into the walls so far from the inflow‡ that the velocity of the stream may be uniform over the area between them. Moreover, a correcting coefficient is required, differing however but little from unity, for the reduction of speed near the walls of the tube. For tubes from 1 to 6 millimetres deep, I find an expression e + ·13 mm., representing the effective depth, may be substituted for e in equation (3).

Since the electromotive forces measured with different conduits are rigorously proportional to the field and to the stream velocity, one may determine by comparison with a standard tube the effective depth of any other tube, which may be extremely shallow, and afterwards use the latter as a secondary standard.

In cases where the electrometer is inconveniently sensitive, a large condenser, say of 2 or 3 microfarads, may be charged by the induced electromotive force and discharged through a ballistic galvanometer. Fields of 50 C.G.S. units may be readily recognised in this way.

I have already used my method in the study of the curves of saturation, and of residual magnetisation of electro-magnets, and propose to apply it in other ways.

* Translation of a note presented to the French Academy of Sciences, January 17th, 1898.

† It is only limited practically by the maximum stream at one's disposal.

‡ Five cm. at least for a tube of 5 mm. in depth.

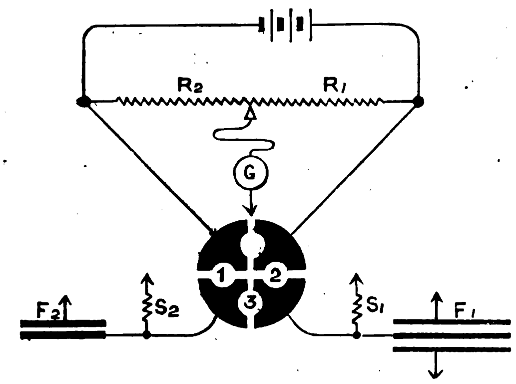
NOTE ON CONDENSER SHUNTS.

By E. RAYMOND-BARKER.

Messrs. H. K. C. Fisher and J. C. H. Darby, of the "Eastern Extension" Cable Company's staff, have lately brought out a book entitled "Students' Guide to Submarine Cable Testing."

There is one matter which might, with advantage, have received some attention from the authors of this admirable and very practical treatise. This matter relates to capacity tests on long cables in connection with the rule first suggested by "F. W.," of Alexandria, in the *Electrician* of February 5th, 1892, namely, that if the dielectric resistances of cable and condenser be in inverse ratio of the respective capacities, a dead-beat Thomson or Gott balance can be obtained without any attendant necessity for correction for difference in absorption.

This means, in other words, that cable and condenser, either one, or both, must, for the rule to apply, be so shunted that the dielectric resistance (D R) *per microfarad* be the same in both the inductive systems.



s_2 and s_1 in above block should be reversed.

A moment's thought shows the correctness of this rule, and one or two illustrative examples in this connection may not be amiss in this "Note."

A pretty exemplification, by the way, of the above rule is the practice, adopted when feasible, of using a real cable of comparatively short length, and therefore easily standardised, as a standard against which to compare a much longer cable, the capacity of which is required to be known as a check on factory values for, let us say, final tests after the laying of a cable. Where this device is practicable, and the cores are of similar material, and of like characteristics in regard to D R and capacity, a Thomson capacity test requires no correction.

This simplification becomes all the more certain in effect if attention be paid to the law enunciated for the first time by Messrs. Fisher and Darby in their afore-mentioned treatise, viz.,

Time of charge = K R *seconds*.

where K = total capacity of cable in *farads*.

R = total conductor resistance in ohms.

Since the D R of a given core varies directly, and its capacity inversely as $\log \frac{D}{d}$, the D R of any given core clearly varies inversely as its capacity, and where, after a correct time of charge, this relationship exists on both sides of a Thomson or Gott capacity balance, the expression $\frac{F_1}{F_2} = \frac{R_2}{R_1}$ holds good without need of correction.

A slight fault in either cable, in the above-mentioned example, or a decided difference in the D R characteristics in the gutta-percha used in the two cables, would necessitate application of the shunting principle. Much more would this be so when a cable of comparatively low D R per microfarad is balanced against a standardised paraffin-paper condenser of very high D R per microfarad.

The following is a practical example:—

F_2 = capacity of standardised condenser = 100 microfarads.

F_1 = known approximate capacity of cable = 750 microfarads.

I_1 = total D R of cable = 7·2 Ω.

I_2 = D R to which standardised condenser with a total D R of 315 Ω (I_3) has to be reduced in order to be proportionate to I_1 inversely as the respective capacities.

$$\frac{I_2}{I_1} = \frac{F_1}{F_2}.$$

So $$I_2 = \frac{F_1}{F_2} I_1 = \frac{750}{100} \times 7{\cdot}2 = 54\ \Omega.$$

What then will be resistance of shunt S_1 which, applied to I_3 of 315 Ω, will reduce D R to 54 Ω?

It is clear that $$I_2 = \frac{I_3\, S_1}{I_3 + S_1},$$

from which $$S_1 = \frac{I_3\, I_2}{I_3 - I_2} = \frac{315 \times 54}{315 - 54} = 65\ \Omega,$$

the application of which resistance between the condenser terminals equalises the respective D R's per microfarad, viz.:

Condenser:—54 × 100 Ω microfarads = 5,400 Ω per microfarad.

Cable:—7·2 × 750 Ω microfarads = 5,400 Ω per microfarad.

The shunt of 65 Ω may be found inconveniently high; the plan may, therefore, be adopted of shunting the cable down to, say, 1 Ω (I_4), the condenser shunt being then re-adjusted to suit new conditions.

I_1 of 7·2 Ω to be reduced to I_4 of 1 Ω must be shunted by

$$S_2 = \frac{I_1\, I_4}{I_1 - I_4} = \frac{7{\cdot}2 \times 1}{7{\cdot}2 - 1} = 1{\cdot}16\ \Omega,$$

which may be distributed in two leaks, each of 1·16 × 2 = 2·32 Ω, one at each end of the cable.

Resistance I_2 to which I_3 of 315 Ω has, under the new conditions, to be reduced

$$= I_2 = \frac{F_1}{F_2} I_4 = \frac{750}{100} \times 1 = 7{\cdot}5\ \Omega,$$

and for this effect to be produced I_3 has to be shunted by

$$S_1 = \frac{315 \times 7{\cdot}5}{315 - 7{\cdot}5} = 7\ 68\ \Omega.$$

The respective D R's per microfarad have now become:—

Condenser:—7·5 × 100 Ω = 750 Ω per microfarad.

Cable:—1 Ω × 750 = 750 Ω per microfarad.

By means of glass tubes of distilled water with non-oxidisable terminal wires, high resistance shunts are easily extemporised and adjusted.

Distilled water in a tube of 50 mils. (approx.) interior diameter was found to give 4·13 Ω per inch of tube against an approximate 0·21 Ω per inch for tap water, both at 60° Fah.

With glass tubing bent under heat into a compressed helix with non-oxidisable contact wires introduced at short intervals, a convenient and compact adjustable high resistance may be devised.

Other liquids of greater or less resistance may be used as circumstances suggest. Under certain conditions, plumbago or lead pencil lines of various thicknesses on a smooth but unpolished ebonite surface prove of service, but liquid resistances show a steadier constancy.

Anent the Thomson capacity test, Messrs. Fisher and Darby remark that it is omitted from their book as the test requires a special key. The above diagram shows how an ordinary quadrant pole-reverser may be used: 1 and 2 being plugged for charge, and 3 for mixing. The best key for this test is the Silvertown mixing key designed by Mr. W. A. Price. It is, electrically, the same as the Lambert mixing key, but enjoys the advantage of good rubbing contacts, and extreme simplicity in construction.

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. Thompson & Co., *Electrical Patent Agents, 322, High Holborn, London, W.C., to whom all inquiries should be addressed.*]

7,398. "Improvements in dynamical machines." F. Stolze. Dated March 28th.

7,408. "A new or improved electricity meter." W. Holmes. Dated March 28th.

7,423. "Process for the extraction of pure metals or metallic alloys and carbides by electric heat." H. Aschermann. Dated March 28th. (*Complete.*)

7,450. "An underground electric current delivery for street railways." H. Daniel. Dated March 28th. (*Complete.*)

7,455. "Improved method of making the active mass in accumulators." F. Frentzel. Dated March 28th.

7,467. "Improved means applicable for use in operating electrically illuminated signs, advertising media, or the like." W. T. Bell. Dated March 28th.

7,470. "Improvements in apparatus for effecting electrolysis." W. L. Wise. (Solway & Co., Belgium.) Dated March 28th.

7,471. "Improvements in electrolysis." W. L. Wise. (Solway and Co., Belgium.) Dated March 28th.

7,487. "Improvements in electric batteries." B. M. Minton-Senhouse and G. F. Emery. Dated March 29th.

7,514. "Improvements in plates for battery and other purposes, and method of making same." A. Warburton. Dated March 29th.

7,545. "Apparatus for electrically winding springs or weights for clock movements." G. K. B. Elphinstone. Dated March 29th.

7,566. "Improvements in systems of electrical distribution." W. L. Bliss. Dated March 29th. (*Complete.*)

7,569. "Improvements in electric furnaces." H. H. Lake. ("Volta," Societe Anonyme Suisse de l'Industrie Electro-Chimique, Switzerland.) Dated March 29th.

7,570. "Improvements in, and relating to, means for connecting electric cables." F. Clouth. Dated March 29th.

7,575. "Improvements in furnaces for manufacturing calcium carbide, &c." W. P. Thompson. (C. L. Wilson, C. Muma, J. W. Unger, H. Schneckloth, A. P. Brosius, and J. C. Kuchel, United States.) Dated March 29th. (*Complete.*)

7,577. "Improvements in electrical batteries." N. B. Stubblefield. Dated March 29th.

7,583. "Improvements in and connected with electrical switches." H. C. E. Jacoby and White, Jacoby & Co., Limited. Dated March 29th.

7,586. "Improvements in magnetic separators." A. M. Clark. (The Metallurgische Gesellschaft A. G., Germany.) Dated March 29th.

7,700. "Improvements in and relating to shields for incandescent electric lamps and the like." J. Dewar. Dated March 31st.

7,725. "Improvements in holders for incandescent electric lamps." J. M. Huisman and H. C. Gover. Dated March 31st.

7,731. "An automatic electric fog and general signal apparatus." C. Cropp. Dated March 31st.

7,754. "Improvements in and connected with electric motors for motor vehicles, launches, and for other driving purposes and in gearing to be used therewith." J. T. Robson, C. H. Marsden, and H. W. Headland. Dated March 31st.

7,764. "An improved apparatus for the electro-deposition of metals." J. H. Hope. Dated March 31st.

7,825. "Improvements in interchangeable electric signs and the like." C. Raleigh. Dated April 1st.

7,855. "Improvements in transmitting electric impulses and signals and apparatus therefor." E. Wilson, H. Godsal, and C. J. Evans. Dated April 1st.

7,862. "New or improved combined globes and shades for incandescent electric lamps and for electric arc lamps and for facilitating the application of advertisements thereto." E. Bohm. Dated April 1st.

7,873. "Improvements in telephones, electric bell pushes, and the like." A. Anders and Veritys, Limited. Dated April 2nd.

7,895. "An improved construction of fusible cut-out for electric circuits." T. Barton. Dated April 2nd.

7,903. "Improvements in electric interrupters." J. M. D. Soule. Dated April 2nd. (*Complete.*)

7,907. "An improved electrical cut-out." L. Greig. Dated April 2nd.

7,929. "High insulation electric light switch." T. L. Jones. Dated April 2nd.

7,940. "An improvement in coin-freed electric meters." T. H. Minshall. Dated April 2nd.

7,961. "Improvements in electric switches." A. Wilson. Dated April 2nd.

ELECTRICAL PATENTS OF 1884, EXPIRING IN APRIL, 1898.

We are informed by Messrs. W. P. Thompson & Co., that about 90 applications for electrical patents were filed in the month of April, 1884. Out of these only four have been maintained to run their full length of term, viz., 14 years, and being of considerable interest we give short abstracts of them below :—

6,288. "Improvements in the adjustments of the mariners' compass." S. M. Moore. Dated April 12th, 1884. Relates to magnetic compasses. The correctors for controlling the errors of the compass are attached to the bowl itself, instead of to any fixed part of the case, thus securing an invariable position and action of the correctors to the compass needle. The magnets for the cardinal errors are placed in a chamber fixed below and forming part of the bowl. They consist of brass rods with a core of magnetised iron of various thickness and are made of uniform size to allow of their being readily interchanged. They are clamped in brackets working in slides of the sides of the chamber, and can be adjusted to any position and fixed by set screws. The quadrantal correctors consist of two balls of soft iron placed in a line with the magnets of the card and adjustable to and fro by screws. They may be fitted either inside or outside the bowl with fluid compasses; they are enclosed in brass cylinders if in bowl. The final adjustment to make the card horizontal is effected by the eccentric weight. 3 claims.

6,414. "Improvements in apparatus for the extraction of metals from their haloid compounds by means of electrolysis." L. A. Groth. (R. Gratzel, Germany.) Dated April 16th, 1884. The haloid salt of a metal such as magnesium or aluminium is melted in a vessel. The positive and the negative electrodes, the latter, and sometimes the former, are surrounded by a cylinder of non-conducting material. The negative electrode may or may not project through the open bottom. The vessel is closed and a pipe is provided for the escape of the haloid gas. "Regenerative" pieces, consisting of an oxide of the metal and carbon may be placed around the positive electrode. Several pairs of electrodes may be placed in the one melting pot.

6,734. "Improvements in electric generators and in working them by fluid pressure." Hon. C. A. Parsons. Dated April 23rd, 1884. Relates to dynamo-electric machines which are specially constructed to be driven by the high-speed turbines described in specification No. 6,735, A.D. 1884. The turbine and dynamo have a common axis, and are mounted on the same bed-plate having a bearing between them. The bearings are specially constructed to permit a slight lateral play, as described in the above-mentioned specification. Lubrication and cooling are effected by the circulation of oil supplied by a pump, which is forced through the hollow shaft. The armature is of the drum type, and the core consists of a number of insulated iron discs arranged on the hollow shaft. At the ends are insulating washers, followed by brass washers forced up by a nut. The iron discs are pierced with channels for the reception of the conductors, or the conductors may be bound with pianoforte wire. The commutator consists of several rings of gun-metal segments held by locking steel rings.

6,770. "Improved means for measuring electric currents." H. Aron. Dated April 24th, 1884. Relates to apparatus for use as a coulomb meter or wattmeter, in which the current is caused to regulate the rate of a clock by acting upon the pendulum or balance-wheel, a magnet or coil attached thereto being acted upon by a stationary coil or coils, or magnet, in such a way as to vary the rate of the clock, and the effect being sometimes increased by iron cores or pieces. In the case of a clock with a balance-wheel, the spring itself may be magnetised. The measurements are made by comparing a clock, influenced by the current, with a normal clock, or by using two clocks, one or both of which may be acted upon by the current, which impart their motion to a differential counter. Various modifications are described.

THE LIVERPOOL OVERHEAD RAILWAY AND DOCKS.

A TIMELY article in *Cassier's*, by Mr. S. B. Cottrell, of the Liverpool Overhead Railway, will be welcome to those who hold that there is no necessity to go to America for electrical railway plant. Everyone seems to have forgotten the excellent working of this line.

The bulk of Mr. Cottrell's article is descriptive and general; but we may, at the risk of repetition, give again the salient figures of the motive power. The trains originally consisted usually of two 45 feet double bogie cars; the bogies, at 32 feet centres, have each four 33-inch wheels. Each car carries 58 passengers, first and second class. There are now three cars to a train. The motor armatures are series wound and ungeared, being direct on the axles of the cars, no special locomotive being used. Each motor gives 1,790 lbs. traction with 120 amperes, or 107 lbs. per ton of train.

A fully loaded train of three coaches weighs 57 tons, of which 9 tons 10½ cwt. is due to the motor equipment. There were originally six 30 feet × 8 feet Lancashire boilers and four horizontal compound 400 I.H.P. engines, each driving a dynamo of 500 amperes × 400 volts. The combined efficiency is 85 per cent. at full load. The additions since starting have been two more condensing engines of surface condensing type, and also of 400 I.H.P. each, at 100 revolutions, with 120 lbs. boiler pressure. The fly-wheels are 14 feet diameter, grooved for 19 1¼-inch ropes.

As usual with rope-driven dynamos, we observe that the dynamo pulley is placed lower than the top of the fly-wheel, so that the ropes, as they travel to the dynamo, are always tending to throw off the face of the pulley. This is wrong practice. Sudden changes of load are apt to cause the ropes to leap in a huge hump and slip badly on the dynamo pulley. A dynamo pulley top ought to be higher than the top of the driving pulley, so that the rope, running towards the dynamo, tends to run under the driven pulley, to encircle as much of the pulley rim as possible, and so prevent the humping which occurs on change of load. Rope driving is condemned by many electrical engineers. We cannot call to mind any place, unless it be at the large Deptford station, where proper considerations of the dynamics of rope driving have been allowed to influence design. Dynamos are almost always placed so that the ropes run down hill to the driven pulley. This is never done in factory driving, and rope driving is successful there, but the lowest set of ropes is often but little removed from the wrong placing, and the slack sides of this set of ropes is often noticeable as running so much less steadily than the up-running ropes.

The later dynamos at Liverpool are 500 amperes × 500 volts each, and they weigh each 24½ tons. About 80 acres of surface have to be painted every two years. By pneumatic process the cost of this painting, including all materials, has been reduced from 2·25d. to 1·24d. per square yard. The motors run 40,000 miles before repairs are required. They earn £200 in that time, and can be rewound for £25.

The importance of Liverpool is to be judged by the fact that it is equal to London in the value of its trade, and much exceeds London in bulk of trade, dealing in articles of less mass value. Liverpool is the biggest grain centre in Europe. It is also remarkable in that its docks extend in a continuous line along a river front for several miles, and it is the passenger traffic of this line of docks and accessories which is served by the electric line. The old 'bus route only carried 2½ million passengers annually; the electric line carries now nearly 9 millions. Yet it is certain Liverpool has not increased in either trade or population by a tithe of the increase of passengers.

In face of this remarkable fact, we have the management of the London Underground shivering on the brink of electrical enterprise, seeing their trade liable to slip away any day in dirt, gloom, and sulphur, yet afraid to make the plunge necessary to success. The success of the Liverpool line ought to be sufficient to show how traffic may wait for facilities and expands as soon as facilities are afforded. Of course, there is no comparison between the convenience of the electrical line and of the old 'bus line which used the rails of the dock railway, but the old 'bus line was practically the only means of travel along the line of docks, and might have been argued to take all possible traffic. Given the facilities for more convenient travel, and the travel has at once sprung up. It is simply by acting on this principle that America owns its thousands of miles of electrical railway, while there are so few in England, even with so good an example as Liverpool for encouragement.

Weatherproof Wire.

In his interesting letter published in our last issue, Mr. Dow has unfortunately misunderstood the first of our questions, "How is it possible to maintain such circuits in wet weather?" Our query did not refer to the maintenance of a high insulation resistance, which we consider, in agreement with Mr. Dow, is quite unnecessary for the working of the line so long as the leakage is uniformly distributed and is not due to one or two weak places; but did refer to its maintenance in good repair. The question was asked, because in one part of the paper on which we were commenting, Mr. Dow stated that the first rainy days of autumn might always be expected to produce a fair crop of burn-outs and earths, and in another part he stated that work bringing the linesmen into proximity with the wires should never be attempted during bad weather; and it appeared to us difficult to understand how the line was to be maintained in good working condition, and a good service given, if repairs were not to be attempted without stopping down all the circuits.

Testing an Enormous Electric Beacon.

Some interesting tests are now being made at the general depôt of the United States lighthouse establishment at Tompkinsville, Staten Island, upon a gigantic electric beacon known as the Lepaute bivalve or lightning lens light. We are indebted to the *Electrical World* (N.Y.) for some interesting details respecting this installation. The lantern consists of two lenses, each 9 feet in diameter, enclosing between them an electric arc of great power. In the central portion of each lens is a disc having two prismatic rings. Outside of this are 190 prismatic segments so arranged that the light of the arc is totally reflected in each and thrown out in a beam practically non-divergent. In this way nearly the total light of the arc is concentrated in two great beams, 9 feet in diameter, directed toward opposite points on the horizon. The whole apparatus is floated on mercury, and is driven by a powerful clockwork actuated by a spring. The period of revolution is once in 10 seconds, so that every point on the horizon receives a flash from the lens in each 5 seconds, these flashes being of about $\frac{1}{10}$th of a second duration. The lamp, lenses, and supporting framework weigh about 20 tons, and the friction is so reduced by the use of the mercury float that the whole apparatus can be easily turned by the pressure of one finger. The arc lamps, of which the lens contains two, one at its focus and the other arranged to be brought into play immediately upon the failure of the first, are of a curiously complicated structure, and yet very simple in principle. The arc is struck by hand. The two carbon holders are connected together by means of a chain actuated by clockwork, the last wheel being a detent, in which is engaged a small pawl, operated by an electro-magnet in shunt around the arc. When the arc lengthens out and its resistance increases, this coil pulls away the detent and permits the clockwork to feed the carbons together. The lamps are of the most elaborate construction and finish, but it cannot be said that the complexity commends itself to the engineering sense. Both lamp and lens were made by Henri Lepaute, Paris, and the whole outfit was exhibited at the World's Fair, and subsequently at Atlanta and Nashville. It was purchased by the United States Government, but its location has not yet been determined upon, though it will likely be installed at some point along the Atlantic coast, if the tests now in progress are satisfactory. There is every indication that they will fulfill every condition imposed upon the apparatus. The lamps are arranged to carry carbons of from 15 to 60 millimetres (⅝th to 2½ inches) in diameter, and the current consumption varies, of course, with the size of the carbon. The original apparatus was provided with an alternating current generator of French make, but it has been decided to use with the lens an alternating generator made by the General Electric Company, driven by a 25 H.P. Ideal engine, which takes its steam from a 25 H.P. Fitzgibbons boiler. The present tests are being conducted with current taken from the local lighting service, the frequency being 140 cycles per second, and the consumption with 30-millimetre carbons being about 60 amperes at 55 volts. It is estimated that the horizontal candle-power of this arc without the lenses is not less than 9,000. Mr. C. A. Lamy, superintendent of the lighthouse depôt at Tompkinsville, estimates that the total candle-power of the two beams of light is not less than 90,000,000. He arrives at this figure by adding together the candle-powers of the various beams emerging from the prismatic part of the apparatus and the lenses. The beam is of enormous power, and will be easily visible at a distance of 100 miles, if mounted in a sufficiently high tower. The light can be located even when mounted in towers of ordinary height at a greater distance than this, on account of the reflection from the clouds of the strong beams. When the lantern is installed in service the electric generating plant will be in duplicate throughout, to avoid any possibility of an accident. It is curious to note that the constructors of this apparatus seem to prefer clockwork for its rotation. With the alternating current supplied for the arc, there seems to be no reason whatever why the rotation of the lens should not be accomplished by means of an alternating motor, a far simpler and more reliable device than the elaborate and complicated clockwork now connected with it. The lens was set up, and the tests are now being conducted, under the supervision of Lieut.-Col. D. P. Heap, Corps of Engineers, U.S.A., Engineer of the Third Lighthouse District, who is ably assisted by Mr. Lamy, Assistant Superintendent.

THE UTILISATION OF BLAST FURNACE GASES FOR ELECTRICAL POWER TRANSMISSION.

By W. H. BOOTH.

A REFERENCE appeared in these columns some little time ago to the tests made by the writer upon the electric light plant laid down at the Wishaw Iron Works of the Glasgow Steel and Iron Company for the purpose of proving the value of the Thwaite-Gardner system of utilising the waste gases from blast furnaces for producing power. At Wishaw the power generated is distributed over the works for the purpose of lighting up the furnaces, the residuals plant and the offices, arc and incandescent lamps being used. The gases which leave a blast furnace do so at a comparatively low temperature, usually not far from 500° F., more or less, or not so hot as the waste gases from many boiler furnaces. Possibly it is because of this, and because the waste gases are partially employed to heat the hot blast, that it is so often claimed that the blast furnace is an economical "machine." True as regards the total heat generated, which may be considered as represented by the maximum temperature at the zone of fusion, the proportion of heat utilised may seem great, but in stating this the true facts are ignored. There are only three products from a blast furnace. One of these, at present considered the primary product, is iron. This is run from the furnace at a temperature of, say, 2,800° F. As the specific heat of iron is only about 0·113, or, say, one-ninth that of water, the heat carried away by a ton of iron is only equivalent to that carried off by a ton of water at about 311° F. Assuming 25 cwt. of fuel at a calorific value of 15,000 B.T.U. per pound, the heat waste per ton of pig is only represented by about 46 lbs. of fuel, or 1½ per cent. of the total fuel.

A further amount of nearly 3 per cent. of the fuel disappears in the 80 lbs. of carbon which enters into combination with the iron. Probably another 3 per cent. disappears in the slag, which is also run out at a high temperature, and, if worth the expense of apparatus, could be made to give back this heat in heating the blast. Altogether about 7½ per cent. of the fuel energy appears at the tapping holes, and certain other heat disappears in chemical changes, in setting free CO_2 from its combination with the ore or flux. Then probably there are 15,000 lb. of gases per ton of iron with a specific heat of 0·25 at 500°. This represents the heat of 125 lbs. of fuel, or about 4½ per cent. of the fuel. This heat is more or less recoverable in heating the blast. It is thus perfectly clear that the waste gases must contain

TABLE I.

	Blast furnace gas. Wishaw.	Blast furnace gas. Frodingham.	A gas producer.
Carbonic acid	5·75	6·0	6·6
Carbonic oxide	24·75	27·3	19·6
Hydrogen	2·33	1·5	6·4
Marsh gas	0·75	...	1·3
Nitrogen	66·42	65·2	66·1
	100·0	100·0	100·0
Heat units per cubic foot ...	97·8	96·7	98·0
Calculated cubic feet per I.H.P.	79·44	80·34	79·27
Percentage combustible ...	27·83	28·8	27·3

not much less than 88 per cent. of the total heat capacity of the fuel. As this is not visible as temperature, it must be visible in some other form, and it is so visible as the calorific capacity of carbon monoxide, of which gas the effluent gases of a blast furnace contain about 28 per cent.

In two samples of gas, No. 1 from Wishaw where, as usual in Scotch furnaces, coal is the fuel employed, and No. 2 from Frodingham, where coke will be used and where a Thwaite plant is also at work, these percentages are seen to hold good.

Blast furnace gas is thus fully equal to gas from a producer. A producer is recognised as yielding a gas capable of working in a gas engine. Yet the blast furnace gas of equal quality has required considerable demonstration to convince people of what an analysis ought to have been sufficient to indicate to them.

Approximately about three-tenths to one-third of the waste gases are combustible, the remainder being diluents, and calculated on this basis from the analysis of the gas, a full half of the original calorific value of the fuel remains, apart from the sensible heat, the difference between the 50 or 60 per cent. remaining, and the above 88 per cent. being accounted for in the latent heat absorption of the wet materials and the gasefying of locked up CO_2 of the ore and flux as well as in loss by radiation and connection through the furnace walls, and by a margin of safety.

If we base our calculations on the low assumption of one-half the fuel being available for power, and we know that a liberal allowance for a horse-power-hour in a gas engine is 1 lb. of fuel, we may calculate the horse-power of a blast furnace as being 1,120 H.P. per ton of fuel used per hour, or 1 H.P.-hour per 2 lbs. of fuel, of which 1 lb. is given over to the purposes of the furnace and 1 lb. remains for power purposes. These figures which are calculated on liberal assumptions are more than borne out in practice. At the time of the writer's tests, the furnaces were delivering a poor quality of gas, yet on the assumption of only 180,000 cubic feet per ton of fuel fed to the furnaces, the measurement of the current generated by the dynamo, and of the gas drawn from the holder meter in runs of five minutes, only showed a fuel consumption of 1·656 lbs. per electrical horse-power, which is to say, that for each 1·656 lbs. of fuel used one horse-power of electrical energy could be delivered at the dynamo terminals. If, as seemed probable, the furnaces were producing 200,000 cubic feet of gas per ton of fuel, the fuel per electrical horse-power would only be 1·49 lb. or with an efficiency of 75 per cent. between terminals and cylinder, about 1·12 lb. per I.H.P. The works manager obtained better results than these, but not more than would be accounted for by known variations in the quality of the gas, which may vary its proportion of constituent combustible between 28 and 38 per cent. As there is considerable divergence among different authorities as to the number of cubic feet of gases produced for each ton of fuel consumed, I have prepared Table II. for the purpose of showing in the particular analysis given of the gas at Wishaw how much is really produced, observing that this particular analysis is of a more than ordinary poor gas, the volume of diluent nitrogen being very great—over 66 per cent. of the volume.

From this table it appears that 100 cubic feet of gas weighs close upon 8 lbs., so that the average specific gravity in pounds per cubic foot is 0·079 as might be expected from the large percentage of nitrogen and of carbonic oxide, both which have the same specific weight of 0·0784. The heavier carbon dioxide brings up the average slightly.

From the table it appears that of the total weight of gas, 1·0503 consist of carbon, the bulk of which is derived from the fuel: it is evident that 1 lb. of carbon represents, therefore, 7·525 lbs. of gases. An ordinary blast furnace practice allows 12 cwt. of limestone flux to each 20 cwt. of coke. Basing some further figures on this ratio, 6 : 10, we may, for a coke furnace, make the following equation:—

$$\text{Carbon in 10 cwt. of coke} = 10 \qquad = 10$$

$$\text{,,} \quad 6 \quad \text{,,} \quad \text{flux} = 6 \times \frac{C}{Ca\,CO_3} = 0{\cdot}72$$

$$\text{Total} \quad \ldots \overline{10{\cdot}72}$$

The fuel carbon thus represents $\frac{10}{10{\cdot}72} = 98$ per cent. of the whole, and we may, therefore, say that each pound of carbon in the fuel will represent 98 cubic feet of gas, so that one ton of fuel will yield 217,000 feet of gas.

These figures are not absolute for the particular analysis, because it cannot be accurately known how much of the hydrogen of the bituminous coal used in this furnace, as usual in Scotch practice, is converted into steam and cannot appear in an analysis of permanent gases, but they are sufficient to indicate that the figure of 180,000 feet per ton of fuel will not be far wrong for a coal burning furnace when using a less amount of air. From 80 to 100 feet of gas may be therefore assumed correct per pound of fuel used, and as it is very easy to test the volume of gas consumed by an engine, the power output per pound of fuel is readily found.

The calculations of Table I. are of course based on the customary temperature of 0° Centigrade. Any test figures as to consumption of gas by an engine will show 10 to 12 per cent. more consumption than if measured at the base temperature, the gas in the holder during my own tests being about 550° F. absolute temperature. It need not really concern us how much heat disappears in volatilising the carbonic acid and oxygen locked up as solids in the flux and in the ore. The only items required are the total carbon which enters the furnace and the weight of carbon in the gases. Knowing these two quantities it is easy to calculate the amount of combustible gas produced by a ton of fuel so long as we have the proportions of CO and CO_2 into which the carbon is more or less oxidised. The complicated conversions and reconversions, and general chemical reactions between the tuyeres and the furnace top need not concern us at all. It is of course a point with metallurgists to obtain as much CO_2 as possible

TABLE II.

Gas.	Per cent. Volumes.	Weight per cubic foot.	Weight per 100 cubic feet of mixed gas.	Ratio of constituents.	Actual weights of elements per 100 cubic feet of gas.			
					C.	O.	H.	N.
Carbonic oxide = CO	24·75	0·0784	1·9404	3 : 4	0·8316	1·1088	...	...

as an indication of fuel economy, but Lowthian Bell has shown there is a limit below which the ratio of CO must not fall, and, with power an important product, the straining after a high percentage of CO_2 would be unnecessary and undesirable. The power system thus frees the blast furnace management of considerable anxiety, rendering fuel waste impossible—indeed, desirable as furnishing a better gas, for with all the gas used as power, there would be no object in making any more carbon dioxide than could possibly be helped. The estimate of 1 horse-power from each 2 lbs. of fuel is thus well within the mark.

(To be continued.)

"FREE" AND "EASY" PAYMENT SYSTEMS OF HOUSE WIRING.

By V. ZINGLER, A.I.E.E.

THE above title must not be taken literally, or as the heading of a scheme whereby it is sought to show that the debtor of a wiring company is under no further moral obligation to pay his bill to them than he is to his tailor; it is merely a summary of the names of two systems, whereby the distribution of the electric light is to be made more universal, to the mutual advantage of the public and the wiring firms or electric light companies, the corporations being after all the public also.

With the free wiring system—improperly so called—we are all more or less familiar, although there are points in connection with its application which have no doubt not been fully considered. But with the easy payment system the public has not been made familiar, for the simple reason that no financial or wiring firm would be able to get their shareholders to put their money into a concern which would have to spend any amount of money with only the chance of getting a small interest in return, and on no further security than that of the consumer's word, with the alternative of a lot of installations thrown back on their hands, only partly paid for, and situated in property belonging to other parties.

If, however, some solid security for the payment of this class of work could be obtained, the matter would have a different aspect; and in a recent report to the Electricity Committee of the Plymouth Corporation, Mr. John H. Rider, the borough electrical engineer, sets forth a scheme of some boldness, with which it is our intention to deal in comparison with the alternative scheme of the National Electric Free Wiring Company.

After reciting some of the aims and methods of the scheme now in use by the latter company, Mr. Rider proceeds to point out that the system of paying an extra sum per unit—this excess being interest on the capital sunk in the house-wiring, &c.—is very unfair to the consumer, because the percentage will rise as the price per unit is reduced. That is to say, at 8d. per unit an extra charge of 1d. is 12½ per cent., whereas at 4d. it would be 25 per cent. He also points out that under this system the more electricity is used the more the customer has to pay for fittings, and he classes this as unfair also. But is not this itself an unfair way of looking at the matter? It may be assumed that the average consumer will use about as much electricity whether he pays 4d. or 8d. per unit for it—that is to say, the class of consumer for whom the schemes cater. He has a fixed number of lamps in his villa, or shop, and he uses just those lights which he wants. Therefore, he is not likely to use much more electricity at the lower rate than he uses at the higher rate; and as there is nothing to prevent a supply company from putting down its rate per unit, any proportional reduction of the excess for wiring would mean a diminution of income to the wiring company unless it could be proved that the consumption of electricity increases in inverse proportion to the rate per unit.

As regards the amount of electricity that a consumer uses, is it certainly not fairer that he should pay in a certain proportion to the actual use he gets out of the wiring and fittings rather than for the length of time these goods are in his house? If a man hires a piano, he has to pay an exorbitant interest on the value of the same, irrespective of the fact that he may hardly use it at all; whereas, if he had to pay a certain rate for the number of horse-power-hours which he put into the piano, or in default of not using it at all, a certain minimum sum representing the value of depreciation plus a moderate interest, it would be much fairer to all concerned. This is the method which the Free Wiring Company have adopted. The Board of Trade units used are proportional to the amount of benefit that the consumer gets out of his wiring and fittings, and there is no reason why he should not pay for it at an equal rate, no matter what the cost per unit of electricity, as the two things are perfectly distinct. It may, on the other hand, be urged that just as it is found profitable to give the customer a rebate on the cost of electricity after a certain consumption per diem, so it would most likely also be advantageous to all parties concerned to give him a similar rebate on the excess sum per unit for wiring and fittings, the point at which this rebate should come into operation being determined by the sum representing fair interest of capital sunk required from him.

Proceeding, Mr. Rider says that the average consumption is about 18 units per 8 C.P. lamp per annum, and he therefore complains that an excess charge of 1d. per unit for fittings, &c., is equivalent to 7½ per cent. per annum, assuming that the cost of fitting up a house comes to £1 per lamp. Now it is a fair question to ask Mr. Rider whether he approves of wiring and fittings being put up for this price, even for a large installation. As a borough engineer, he will know that good work cannot be done for this price; how much less then will it be possible to instal, say, 10 to 20 lights, the size of installation catered for by this system, for £1 per light, including main switch, fuseboard, and making good. Even assuming 7½ per cent. as being the interest paid, is it excessive, when considering that the installation is guaranteed for six months, that the consumer has no liability as to the time he shall use the installation for, and that the company has to take the risk in this 7½ per cent. of fire, default, and depreciation of a neighbourhood, in which cases they are put to the expense of loss of interest or capital, or of taking down the fittings.

The report then goes on to suggest a scheme for spreading the payment over a long time so as to avoid the heavy initial cost; such a scheme could not be operated by private wiring firms, as we all know that in these days of keen competition they are more anxious to receive long credit than to give it. Mr. Rider also points out that this might be done by the Corporation, but that experience has proved that it is unwise for Corporations to undertake wiring work. This is certainly the result of the experiment at Liverpool, where the monopoly held by the Corporation for wiring became so intolerable that there was not—up to a year or two ago—a single good wiring firm in the town. The Corporation looked with jealous eyes on any wiring work obtained by outside firms, and the latter had no cause to complain that the Electricity Department did not enforce their regulations. However, this is a digression.

Mr. Rider's scheme now begins to develop itself in detail. He argues: Wiring firms can wire but not give credit; Corporations must not wire but can give credit; *ergo*, let the wiring contractor do the work, and the Corporation give the credit!

Let us give the scheme in his own words:—

"The wiring contractor would canvass for orders in the usual way, and could carry out work for any customer on his own terms without reference to the Corporation. But when a person wished to avail himself of the easy payment system, he would have to proceed in the following manner.

The quotation to such customer would be made out upon a special form, binding the contractor to carry out the work to the satisfaction and under the supervision of the Corporation, and naming such a price for the work as would permit him to allow a discount of 5 per cent. for cash.

If the customer agreed to this price, he and the contractor would notify the acceptance in writing upon a form of application to the Corporation. This form would set forth the terms of the proposed agreement, which would be somewhat on the following lines, viz.:—

(*a*) That the contractor will carry out the work in accordance with the conditions, regulations, and other requirements of the Corporation, and to the entire satisfaction of the borough electrical engineer.

(*b*) That the contractor will allow to the Corporation a discount of 5 per cent. from the quoted price, for payment within one month of the date of the work being completed and connected to the mains.

(*c*) That the customer will pay to the Corporation the quoted price in full by means of eight equal instalments, the first being sent with the application in the form of a deposit, and will pay a similar amount every three months from and after the completion of the work, until the whole be paid.

(*d*) That the work will remain the sole property of the Corporation, until the full amount be paid.

(*e*) That the customer will be responsible for any damage to the work (reasonable wear and tear excepted) while it remains the property of the Corporation.

(*f*) That all lamp and fuse renewals will be carried out by and at the cost of the customer.

(*g*) That in the event of a customer's payments being more than three months overdue, the supply of current will be liable to be cut off without notice, and proceedings taken for the recovery of the whole amount due.

(*h*) That (if required by the Corporation) the customer to provide two securities for his due fulfilment of the contract.

If the customer, contractor, and price appeared satisfactory to the Corporation, instructions would be given by the Corporation to the contractor to proceed with the work, and upon the proper completion of the same the Corporation would pay him the quoted sum, less 5 per cent."

(To be continued.)

A PORTABLE ELECTRIC RAILWAY.

THE great success of electric street railways has given rise to many attempts to apply electric traction to portable or field railways. In the earlier attempts the style of construction that had been worked out for street railways was applied with little change to the field railways, no regard being paid to the special requirements in the latter case.

A system, which is designed to meet these special requirements, has recently been worked out at the Field Railway Works of Arthur Koppel. From a description of this system in the *Zeitschrift für Elektrotechnik*, February 13th, 1898, we give the following summary:—

As in other railways, the track consists of easily transportable rail frames, made up of two rails of the usual field railway profile 65 to 70 mm. in height, connected together by, say, five crossbars (fig. 1). The overhead conductor is

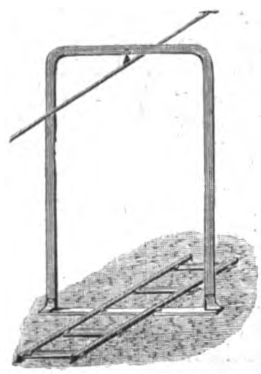

FIG. 1.

supported by a ∩-shaped yoke which is bolted to extensions of the middle crossbar of a rail frame. These yokes are placed about 25 m. apart along the track. The overhead conductor is supported at the middle of the upper horizontal part of the yoke. The weight of such a yoke is about 50 kg. more than that of the ordinary rail frame.

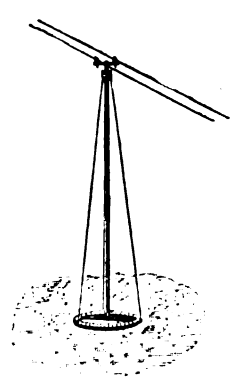

FIG. 2.

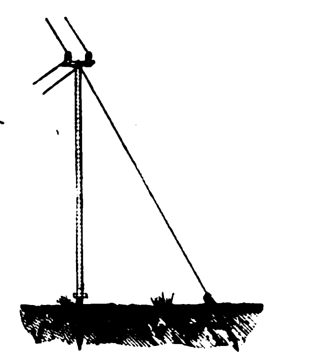

FIG. 3.

These yokes are placed closer together at curves, and at the sharpest curves it may be necessary to fit every rail frame with a yoke in order to keep the overhead conductor sufficiently near the centre of the track.

The generating station is fitted in the usual way with a dynamo which may be driven by a steam engine, gas engine, or turbine, according to circumstances. Two feeders are led from the station to one end of the track, one being connected to the end of the overhead conductor and the other to the rails. The feeders are fitted with safety fuses. The feeders are supported on poles, which may be fixed or transportable, according to the nature of the line. In the former case they are driven into the ground; and, in the latter case, portable stands, fig. 2, with disc pedestals are used when the line is straight, and pointed poles with tension wires, fig. 3, at corners. Where one of the feeders is connected to the trolley wire, it is fastened to one of these anchored poles.

A special truck, fig. 4, has been devised for running the

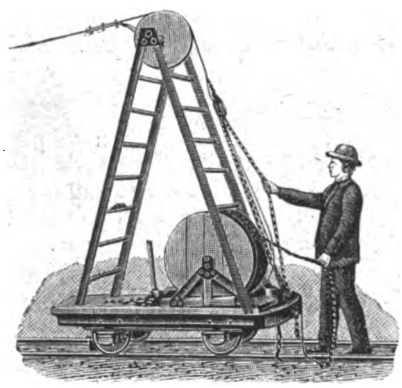

Fig. 4.

trolley wire. On this truck is fitted a reel containing the copper wire, and a pair of ladders supporting a guide pulley at the top. A sufficient length of copper wire is pulled off the reel, passed over the guide pulley and the free end is fastened to the end of the feeder connected to the anchored pole at the end of the track. The fitters' truck is anchored to the rails and the wire is stretched by a block and tackle and fastened to the insulator on the yoke. The truck is now moved along the track till another yoke is passed, when the same operation is repeated. The ladders, reel, and undercarriage of the fitters' truck is made of dry wood saturated with some insulating substance, so that current could not pass from the trolley wire through the truck to the rails.

This precaution is necessary because the end of the trolley wire is left attached to the truck when the position of the track is liable soon to be changed. When the track is to be permanent for a considerable time the end of the trolley wire is fixed to an anchored pole.

The solidly constructed motor car, fig. 5, has, as a rule, a

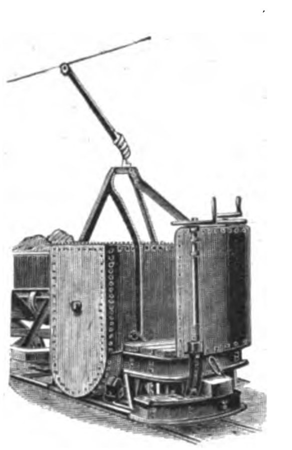

Fig. 5.

motor mounted on the frame of the undercarriage, and geared to the driving wheel axes by toothed gearing and two pitch chains. The frame of the undercarriage is furnished with spring bearings, spring buffers, and coupling arrangements. On the driver's platform is a brake and a switch handle. By means of the latter more or less resistance can be put into circuit, and the speed thereby varied within wide limits.

If the gauge of the rails is 500 mm. or more, the motors can be fixed inside the under-frame of the cars and be connected directly to the axes of the driving wheels by a spring coupling. This construction has the advantage of getting rid of the dead weight of a special motor locomotive, which is of great importance when steep gradients have to be ascended. The electric motor has the advantage over most other kinds of traction in the great range of its output.

These portable railways may be used with great advantage in connection with factories having spare steam power; or having an electric lighting installation. They may be employed for the transmission of goods during the day, and thereby furnish a useful day load to a lighting installation which otherwise would have occasionally to stand idle.

ALUMINIUM WIRES FOR OVERHEAD LINES.

By STUART A. RUSSELL.

The paper on "Aluminium as a Rival of Copper and Brass for Electrical Conductors," reprinted in the Electrical Review (March 11th and April 1st), details very ably all the points in which aluminium may show itself a formidable competitor of copper as an electrical conductor; and the author, Mr. A. E. Hunt, whilst allowing that for insulated conductors aluminium is heavily handicapped by the extra cost of insulation, claims that there is an ample field for the employment of aluminium wire for bare transmission lines, especially for high potential long distance work and for long distance telephone lines. Mr. Hunt quotes figures showing that as the weight of copper is three and a third times that of an equal volume of aluminium, and as the conductivity of the latter is 63 per cent. of that of pure copper (Matthiessen's standard), and further as aluminium wire is now offered for sale at a specially low rate, the prices of an aluminium and a copper wire of the same length and conductor resistance are equal. A comparison is then made between a soft copper wire having a tensile strength of 32,000 lbs. per square inch, and an aluminium wire having the same tensile strength per square inch and a conductivity of 63 per cent. of that of the copper wire, in which it is shown that for equal conductor resistance the sectional area, and therefore also the breaking strain of the aluminium wire will be 60 per cent. greater than that of the copper wire, whilst the weight of the former will only be 48 per cent. of that of the latter.

Mr. Hunt therefore concludes that the aluminium conductor could be used in much longer spans than the copper, and that the number of expensive poles and insulators could be materially diminished. It appears, however, that the effect of wind pressure on the larger aluminium wire has been altogether left out of account in coming to this conclusion, and the writer therefore proposes to give one or two examples to show how this statement must be modified when the effect of wind pressure is taken into account.

Let us assume a wind pressure of 20 lbs. per square foot, which is approximately the figure adopted by the Post Office, and that the ratio of the effective pressure on a cylindrical surface to that on a plane surface is 0·6, then the pressure, P, in pounds per foot run of wire will be numerically equal to the diameter in inches of the wire, and if W = the weight per foot run of wire, the resultant pressure, w, per foot run of wire = $\sqrt{W^2 + P^2}$. Taking as an example the copper wire ·100 inch diameter, and its equivalent in aluminium, of which particulars are quoted by Mr. Hunt, we find for the copper wire—

W = ·0304 lbs.
P = ·100 „
w = ·1045 „
t = safe working strain with a factor of safety of 4 = 63 lbs.,

and for the equivalent aluminium wire, which will be ·126 inch diameter—

W = ·0145 lbs.
P = ·126 „
w = ·1268 „
t = 100 „

To compare these two wires we may find the span, which will give the same dip, say, 5 feet for each, using the equation,

$$a = \sqrt{\frac{8\,d\,t}{w}};$$

from which we get a span of 155 feet for the copper wire, and of 162 feet for the aluminium one, which shows a slight difference in favour of aluminium. This will not, however, permit of any saving in poles, as the side strain on the poles due to wind pressure on the wires will actually be 25 per cent. greater with the aluminium than with the copper wires, and therefore heavier poles would have to be used.

In such small wires the effect of wind pressure is greater than with wires of larger sectional area, as the surface exposed to the wind does not increase so rapidly as the sectional area; and we shall, therefore, find a greater difference in the length of span if we take as an example a copper wire of ·300 inch diameter and compare it with its equivalent aluminium wire, the diameter of which will be ·378 inch. For the copper wire we have—

$$\begin{aligned} W &= \cdot 2736 \text{ lb.} \\ P &= \cdot 300 \text{ ,,} \\ w &= \cdot 406 \text{ ,,} \\ t &= 567 \text{ lbs.} \\ a &= 236 \text{ feet,} \end{aligned}$$

whilst for the aluminium wire we have—

$$\begin{aligned} W &= \cdot 1304 \text{ lb.} \\ P &= \cdot 378 \text{ ,,} \\ w &= \cdot 400 \text{ ,,} \\ t &= 900 \text{ lbs.} \\ a &= 300 \text{ feet.} \end{aligned}$$

The aluminium line would, therefore, need only four poles where the copper line would require five, but part of this advantage would be neutralised by the fact that, as the side strain on the poles due to wind pressure on the line would be 50 per cent. greater for the aluminium line than for the copper one, the poles for the former would have to be of larger diameter.

So far we have followed Mr. Hunt in comparing aluminium with soft copper, but if we compare the wires in the last example with an equivalent hard drawn copper wire of, say, 97 per cent. of the conductivity of the soft copper wire, and with a breaking strain of about 64,000 lbs. per square inch, we get the following figures :—

$$\begin{aligned} \text{diameter} &= \cdot 305 \text{ inch} \\ W &= \cdot 2827 \text{ lb.} \\ P &= \cdot 305 \text{ ,,} \\ w &= \cdot 416 \text{ ,,} \\ t &= 1{,}160 \text{ lbs.} \\ a &= 334 \text{ feet,} \end{aligned}$$

showing that the advantage as to number of poles and also as to side strain on the poles lies with the hard drawn copper wire.

Mr. Hunt says in his paper that experiments are now being made with an alloy of aluminium having an increased breaking strain, and that although these experiments are not yet completed, it can safely be predicted that a wire of aluminium alloy can be furnished with a breaking strain per square inch equal to that of hard drawn copper, and a conductivity of not less than 50 per cent. of Matthiessen's standard. Such a wire would have a diameter about 40 per cent. greater than that of the hard drawn copper wire of equal conductor resistance, and if we suppose that its specific gravity and price per pound remains the same as for aluminium, it would cost from 10 to 15 per cent. more than the equivalent copper wire.

There is another point which should be taken into consideration, and that is, that the coefficient of expansion per degree rise of temperature is nearly 20 per cent. greater for aluminium than for copper, so that if the two wires are to have the same maximum dip in summer, the aluminium wire will have a smaller dip than the copper wire in winter, and will be subjected to a greater strain unless allowance has been made for this by taking a lower working tension in calculating the span from the maximum dip.

A SIMPLIFICATION OF THE MARCONI RECEIVER.

DR. H. RUPP, of Stuttgart, has made an important simplification in the Marconi receiving apparatus, which he describes in the *Elektrotechnische Zeitschrift*, April 14th, p. 237. To restore the resistance of the coherer, Marconi, as is well known, employs an electric tapper, working like the hammer of an electric bell. This taps the coherer tube, loosens the filings and stops the current. This contrivance has been found to be somewhat uncertain in its action, and when a Morse instrument was used the dots and dashes were often not sufficiently separated.

Dr. Rupp dispenses altogether with the electric tapper in his arrangement, and decoheres the filings by causing the tube to rotate on its axis. The rotation of the tube is produced very simply by means of the paper ribbon of the Morse instrument. The leading-in wires of the coherer are mounted in bearings, and a small vulcanite pulley, with flanges, is fixed on one end of the tube. The tube is put in circuit by two small copper springs, which rub on the rotating axes. The paper strip of the Morse instrument passes round the pulley between the flanges.

Fig. 1 shows this coherer partly in section.

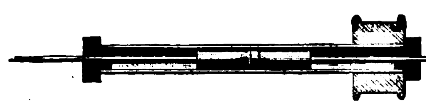

FIG. 1.

The paper spool of the Morse instrument is slightly braked by a brass spring, in order to produce a uniform tension on the paper ribbon, and thereby a uniform rotation in the coherer tube. The arrangement of such a receiving station is shown diagrammatically in fig. 2.

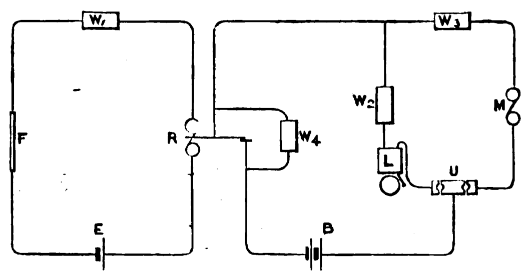

FIG. 2.

In the circuit of the coherer tube, F, there are, in addition to the battery, E, the resistance, W, and the relay, R. By means of the switch, U, either the calling up bell, L, or the Morse apparatus, M, with their respective resistances, W_2 or W_3, and the battery, B, can be thrown into the local circuit; W_4 is a resistance arranged in shunt to prevent sparking at the relay.

Such a station is called up when the tube is at rest, and the bell continues to sound until the Morse instrument is plugged into circuit, and the paper ribbon set in motion.

The diameter of the coherer tube to be employed in this way must not be too small, and the quantity of filings between the silver electrodes must be small enough to roll round the glass wall of the tube. When all the dimensions are properly chosen the dots and dashes stop at the right moment, and the signals are very distinct—certainly much better than with the old arrangement.

Search Lights and Defence.—A committee of naval and military officers at Portsmouth was engaged on Monday night testing the position of the electric search lights distributed among the forts and batteries of the Solent, and to determine whether it was possible for an enemy's torpedo craft to steal into Spithead and effect unperceived an entrance into Portsmouth Harbour under cover of the night.

ELECTRICAL ALLOYS.

By ROLLO APPLEYARD.

Ten years ago German metallurgists began to study the problem of mechanical and electrical permanence of the cheaper alloys used for resistance coils. They appealed to the Reichsanstalt. Metal founders submitted specimens for analysis and criticism, elaborate tests were made, and the results led to the favour and adoption of "manganin" and "constantan." There is still some doubt as to the durability of these alloys, but the evidence shows that, with proper precautions, manganin and constantan may be protected against all ordinary sources of deterioration. The history of that investigation deserves to be told in full, as an object-lesson upon the benefits conferred by a National Laboratory. It is all written in *Band II.* of the *Wissenschaftliche Abhandlungen der Physikalisch-Technischen Reichsanstalt*; parts of it have from time to time been quoted in the Electrical Review and other journals, but several important details have been omitted; it is therefore proposed here to give a summary of the investigation more or less as it appears in the original volume.

I. Metallic Alloys for Standard Resistances.

The first step was to investigate the electrical resistance of most of the familiar alloys, with the intention of elucidating the question of the variation of their specific resistances, for it is these variations that most disturb precise measurements. German silver was next examined, samples being taken from that made by Messrs. Siemens & Halske for standard resistances; also nickel wire from Obermaier, of Nürnburg, and platinum-silver and platinum-iridium from Messrs. Heräus, of Hanau. Of these alloys, the particular quality of platinum-silver examined was found to be too inhomogeneous and too brittle; it had, therefore, to be excluded from the final research.

Platinum-iridium, on account of its high price and great temperature coefficient, was discarded, as it was considered to be only of secondary importance for practical purposes. In the course of the experiments, the nickel used for coins in the Imperial Mint, and manufactured by Messrs. Basse and Selve in Altena, under the trade name of "Patent nickel," was carefully tested.

In order to characterise the materials as nearly as possible, analyses of the various samples were made in the Chemical Laboratory of the Reichsanstalt, with the following results:—

TABLE I.

—	German silver (1 mm.) Messrs. Siemens and Halske.	Nickel. (1 mm.) Messrs. Obermaier.	Patent nickel.
Copper	60·16	61·63	74·71
Zinc	25·37	19·67	0·52
Nickel	14·03	18·46	24·14
Cobalt	Trace	0·19	Trace.
Iron	0·30	0·24	0·70
Manganese ...	Trace	0·18	0·17
Tin	...	...	Trace.
Sp. resistance ...	30·0	33·2	32·8
Temp. coefficient	0·00036	0·00030	0·00021
Thermo-electric power against Cu.	14·4	18·1	29·1

For reference, three physical constants are added to the table:—(1) The *specific resistance* in microhm-centimetres; (2) the *thermo-electric power against copper* in micro-volts per 1° C., temperature difference; and (3) the temperature coefficient.

In the next case, the effect of rolling the wire was investigated at various adjustments of the rollers. Copper pieces were hard soldered to the ends of the wire under test, and the resistance was measured; then, avoiding tensile strain so far as possible, the wire was rolled, and finally its resistance was again determined at the same temperature.

All wires in Table II. show an increase of resistance after rolling, varying from 0·04 per cent. to about 0·87 per cent. Patent nickel varies least, German silver the most. If the diameter of the roller is 40 times that of the wire, only a very small increase in the resistance of the patent nickel wire is observed; with German silver the increase is about four times greater. If rollers of 10 times the diameter of the wire are used, both of these alloys show a change of resistance of about four times the above increment. The cause of this increase of resistance by rolling is partly due to stretch, and partly to mechanical hardening, the result of bending and twisting.

TABLE II.

Specimen of wire.		Diameter of rollers.	Resistance in ohms. Before rolling.	After rolling.	Increase per cent.
1. Standard German silver (Siemens and Halske)	1 mm.	20 mm.	2·2403	2·2575	0·77

Variations due to bending may be prevented very easily and effectively in standard resistances, by attaching the wires permanently to metal with a strong coating of shellac.

The quasi-permanent resistance-changes due to heating of the material are much more serious. In order to investigate them, bobbins of the foregoing metals were heated for several hours in a dry oven at 40° C., 100° C., and 150° C., and then again at 100° C., measuring the resistance before and after every heating. Table III., column 6, shows the alteration of resistance, corresponding to the various temperature ranges.

TABLE III.

	2	100	5·0726	5·0726	0

Patent nickel gives a diminution, German silver and nickelin an increase, of the specific resistance after heating. The first heating, 40° C., produces a slight but definite alteration with all the wires. With the next heatings, 100° C. and 150° C., German silver and nickelin have very nearly the same order of increase, which is approximately double of the diminution exhibited by patent nickel. Heating at 100° C., after previous long continued heating at 150° C., influences German silver and nickelin only very slightly; with patent nickel, as a general rule, there is no difference within the limits of observation. The important results derived from these experiments are: (1) that the specific resistance of German silver and nickelin can be made approximately constant, by prolonged heating at 150° C.; and (2) that the specific resistance of patent nickel becomes, within the limits of observation, perfectly constant under the same treatment, so that it does not undergo any subsequent changes even when heated to 100° C. Secondly, the experiments show that, of the materials investigated, patent nickel is essentially better than German silver and nickelin as a material for standard resistances. The above variations are considered by the Reichsanstalt to be due to the presence of zinc in the German silver and in the nickelin samples.

Resistance Alterations due to other Influences.—Of the other influences that can bring about variations in the resistance of metallic alloys, oxidation has first to be considered. The results show that shellac is effective in preventing oxidation, even with the alloys most liable to be attacked. The thermo-electric force of the above specimens against copper, brings about apparent changes of resistance. These changes are most observable with low resistances used with large currents; but by suitably designing the resistances and apparatus they can be nullified.

Of much more importance are the changes of specific resistance with temperature. There is no means for compensating these changes, they can only be held within limits by careful jacketing in oil baths, meanwhile observing the temperature of the oil. They constitute the principal cause of uncertainty in standard resistance coils, and they form the starting point of the investigations of the Reichsanstalt.

Klemencic studied the properties of platinum-iridium and several other alloys used as standards of electrical resistance. He investigated platinum-iridium, platinum-silver, German silver and nickelin, but without giving analyses of the samples. The Reichsanstalt have since examined some of the nickelin alloys used by him, and they find their composition to be :—

	Copper.	Nickel.	Manganese.
1. Bare wire	75·4	24·6	Trace.
2. Covered wire... ...	75·5	24·5	Trace.

thus corresponding with the patent nickel in Table I.

The different materials were tested with regard to their specific resistance, their temperature coefficients, and their thermo-electric force against copper, also the change of their resistance with time, the influences of mechanical deformation, and of moderate temperatures. As a result of the whole investigation, it is found that German silver is of all the alloys the least suitable material for standards of resistance, since it is the one most influenced by mechanical deformations. In this regard the Reichsanstalt conclusions agree with those of Klemencic. The temperature-changes in Klemencic's experiments, though comparatively small, were quite great enough to produce noticeable acceleration of the resistance variations. He himself says: "It would perhaps be possible to bring newly-constructed resistance coils to a final steady value by submitting them for a considerable time to a fairly high temperature." But he did not pursue this idea very far. In his investigations, platinum-silver, such as was recommended 30 years before by Matthiessen, proved the best; in the Reichsanstalt experiments, however, this material seemed to lack homogeneity. With regard to the use of "nickelin" (patent nickel) of standard resistances, Klemencic says: "it has many good properties, but its high thermo-electric power against copper, and the small degree to which it can withstand chemical actions, must be regarded as unfavourable." This alloy is very generally used in the construction of coils for ordinary resistance boxes.

(*To be continued.*)

American Pigs for the Clyde!—It is stated that a large quantity of American pig iron has been brought into the Clyde at 10s. per ton below the price for which English iron could be obtained in this country, and should it prove equal to specifications, it is said there will be a large importation.

SOME FACTS ABOUT WIRELESS TELEGRAPHY.

There have been many wrong conjectures and misconceptions in this country on the subject of wireless telegraphy. The controversy that broke forth on the question of allocating credit to the originators is no doubt still fresh in the minds of our readers. We are not anxious to revivify the differences that have marked the introduction of this new system of signalling, and to that end we shall, as far as possible, confine our remarks to the experiments that are being conducted in this country by Mr. Marconi. To begin with, however, an error perpetrated by a contemporary which still remains uncorrected ought to be swept away. The postal authorities are not conducting experiments on wireless telegraphy between Bournemouth and the Needles, and never have been. A want of knowledge has attributed to the Post Office what has really been done by the Wireless Telegraph Company, under the supervision of Mr. Marconi.

We have been in touch with the Bournemouth experiments for months past, and last week we had the privilege of taking some part in the transmission of messages between Bournemouth and the Needles by the methods of Mr. Marconi.

It is hardly necessary to say that successful experiments on wireless telegraphy have not been confined to this country. In Italy and Germany indefatigable workers have been able to give very remarkable demonstrations. The most noteworthy are those of Dr. A. Slaby, whose achievements have been often quoted in this country as a means of disparaging Marconi's work. Dr. Slaby himself is more generous, and at the present stage it is interesting to quote the following passages from his recent work :—

"Like many others I have also taken up this study, but never got beyond the limits of our High School. Even with the aid of parabolic reflectors and great capacity I could not attain any further.

"Marconi must have clearly added something new to the knowledge by which distances of a kilometre long were attained. I at once resolved to go to England, where the telegraph authorities were making greater experiments. Introduced through my friend Mr. Gisbert Kapp to Mr. Preece, chief engineer of the English telegraph administration, I was graciously allowed to participate in these. What I saw was something new; Marconi had made a discovery; he worked with means, the full importance of which had not been recognised, and which alone explain the secret of his success.

"I ought to have said this at the commencement of my subject, as later, especially in the English technical press, the novelty of Marconi's process was denied. The production of the Hertz waves, their radiation through space, the sensitiveness of the electric eyes, all are known. Very good; but with these means 50 metres were attained, but no more.

"In the first instance, Marconi has devised for the process an ingenious apparatus which, by the simplest means, attains certain results. He has thus first shown how, by connecting the apparatus with the earth on the one side, and by using long extended vertical wires on the other side, telegraphy was possible. These wires form the main feature of his invention; the term 'wireless telegraphy' is, therefore, really incorrect. It would be more correctly termed spark telegraphy, in contrast to the present telegraphy by the electric current.

"I will first of all discuss the constructive apparatus. The principal part of the apparatus is the electric 'eye.' After many experiments, Marconi considered a metallic powder, or rather a mixture of metallic powders, 96 per cent. hard nickel, and 4 per cent. silver, to be the best. It is produced by filing with clean and dry files. This mixture is sealed in a glass tube between two silver balls, the limited surface of which is slightly amalgamated with mercury. The finer the layer of powder, the more sensitive the 'eye,' *i.e.*, the lower the force of the rays, the better the action.

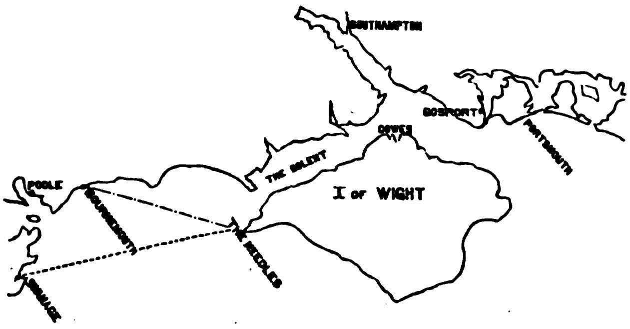
"The layer is only about ½ mm. thick, and only from 20 to 25 metallic grains can be introduced. The exact percentage of silver given is comparatively unimportant; it can only be said that a larger quantity of silver grains make the tube more sensitive, which is of no advantage, as the more silver, the more defective the interruption by concussion after signalling. To effect certain results, which is the main point, I entirely omit the silver, and use only nickel filings. Marconi further recommended the tubes to be exhausted after filling, and hermetically closed. The former is, according to my views, unimportant; the hermetical closing is, however, to be recommended, as it ensures the correct position of the confined silver plungers. The entry is effected by platinum wires, which are welded to the silver plungers. It is, however, of the greatest importance to select with the microscope, metal grains of the most uniform size possible, the sharp edged, jagged and pointed being the most acceptable, and the round grains being the least. Before filling they must be carefully cleaned and dried. In spite of everything one is, however, dependent on chance; some have always to be rejected, partly through having too little or too much sensitiveness, partly on account of an absence of capacity of interruption."

Dr. Slaby, after giving further details of Marconi's apparatus, proceeds to say:—

"Arriving home, I at once commenced to repeat the experiments. I constructed the apparatus in every respect according to Marconi's system. Several simplifications were made subsequently which have proved useful."

The evidence of Dr. Slaby ought to be fairly conclusive that Marconi had made distinct advances on anything previously attempted.

Returning, however, to the experiments at Bournemouth. It is perhaps necessary to say that the Wireless Telegraph Company have had since last November a signalling station at Bournemouth, and one at Alum Bay, on the Needles, Isle of Wight, the position of these places with regard to each other being clearly shown on the section of map. The distance between the two points is 14½ miles, and messages are sent between the two places with facility and accuracy. Swanage is to be very shortly brought into electro-magnetic communication with the Needles.



We have at different times spoken of the apparatus used in Marconi's system,* and at the moment it is scarcely important to refer to the principle in detail, especially as the quotation from Dr. Slaby includes an account of the chief features of Mr. Marconi's system.

A room in one of the houses facing the sea at Bournemouth is fitted up with the necessary apparatus for sending and receiving signals. Even in a locality where masts and flagstaffs are common, the height of the pole facing the signalling station would probably attract attention. It is about 115 feet high, and from the top of this is suspended either an insulated copper wire, or, as on the occasion of our visit, a wire netting some 9 inches in width may be employed. The wire netting is suspended from the pole by means of a long ebonite stick, two coils of wire at this point being employed in order to give an increased capacity. Means are, of course, taken to prevent the netting or the wire coming into contact with the pole. The end of the conductor is carried through a window into the room where the transmitting and receiving apparatus is arranged. Upon entering the room, the scene of such remarkable performances, one is struck with the simplicity, indeed, the sparseness of the apparatus. On a small table near the window is a large 10-inch induction coil, and a Morse key, which forms the sending apparatus, while close by is a metal box some 2½ feet in length, which contains the receiving apparatus, the coherer, a relay and the tapper, while an ordinary Morse printer completes the receiving equipment. A few cells arranged underneath the table completes the apparatus for sending messages across space. After an examination of the instruments, we had various special messages sent by the operator, with a request that they should be repeated; the messages were by no means easy, and, as one was a code message, there was no context to enable the operator at the Isle of Wight end to guess the words. Yet, difficult as it was, the code message came back exactly as it was sent. Altogether we were sending messages backwards and forwards for upwards of an hour, but in no single instance was there any trouble in reading the signals.

As we have already remarked, a 10-inch coil and a Morse key constitute the sending apparatus. The coil at the Bournemouth end is worked by means of a small battery of accumulators. The sparks from the induction coil are made to pass between two small brass balls, about ¾ of an inch in diameter, and placed about an inch apart. In the process of sending a message one sphere of the induction coil would be connected to the end of the vertical wire, while the other would be connected to earth. The operation of the Morse key, by regulating the passage of the current between the battery and the coil, governs the discharge between the spheres, and gives rise to the electro-magnetic waves in the length of vertical wire which affect the apparatus at the receiving station. It is interesting to mention, as showing the tendency to simplify the Marconi apparatus, that in the Penarth experiments it was necessary, for the purpose of transmitting signals over a distance of eight miles, to employ an 18-inch induction coil; but it has been found that perfect signals can now be obtained between Bournemouth and the Needles with a 6-inch coil.

It is necessary, when the sending and receiving instruments are adjacent to one another, to provide a metal screen between them.

Both at Bournemouth and at the Needles the whole of the receiving apparatus, with the exception of the Morse instrument, is contained in a metal box. We need hardly dwell at length upon the receiving apparatus; it consists merely of the coherer, the construction and action of which are well known. The coherer puts into action a one-cell battery, which operates a relay. The relay makes and breaks connection between a 12-cell battery and a Morse instrument, which prints the message. The coherer is about 1½ inches in length and about $\frac{1}{10}$th of an inch in diameter. When receiving a message the end of the vertical wire is connected to the coherer, which then becomes sensitive to electro-magnetic waves. The necessity of decohering exists, and to restore the coherer to its original non-conducting condition, after being affected by the electro-magnetic waves, which go to make a distinct signal, an electrical tapper is provided, which operates automatically and taps the coherer back to its normal state.

After spending a considerable time at Bournemouth dictating messages and having them repeated, we passed over to the Needles to examine the station there. The instruments are arranged in a room in the Needles Hotel, and are practically identical with those in use at Bournemouth. The vertical wire is attached to a mast about 150 feet high, though the entire height of the pole is not utilised. Messages were sent backwards and forwards for some time after we arrived on the island, and at 9 o'clock in the evening of the same day we again witnessed for about an hour and a half the transmission and receipt of messages. Moreover, we availed ourselves of the system to send a telegram to London, the message being sent from the Needles to Bournemouth, and there handed in at the local telegraph office. We had a further opportunity next day of testifying to the facility and accuracy with which signals could be sent and repeated, though it hardly necessitated these various tests to convince us of the successful working of the system. Many of the Morse messages we brought away with us, and a further examination of them demonstrates beyond doubt the clearness and strength of the signals. Admittedly the signals were slow, the average speed in transmission being probably no more than 12 words per minute, but it must be added that no attempts whatever had been made to send fast signals, the aim being rather towards reliability than speed.

The system has now been in use between Bournemouth and the Isle of Wight for some months, and the variations in weather have had practically no marked effect upon the

* A full description of Marconi's apparatus appeared in the Electrical Review for July 16th, 1897.

signals. If there is any difference, it is that foggy and stormy weather is the most favourable for the transmission of signals. The experiments have not been entirely confined to signalling between shore and shore. Quite a large number of successful results have been obtained in signalling between ship and shore in the very worst of weather. In this case a mast, 50 feet high, was erected on a steam tug, and gave excellent signals.

The next move in wireless telegraphy is the erection of a station at Swanage, which is 18 miles from the Isle of Wight; this is in course of construction, and no doubt will soon be in operation. A still more ambitious scheme is in contemplation, and that is telegraphing between the Isle of Wight and Cherbourg, a total distance of 60 miles. We need hardly say we shall follow these experiments with the greatest interest.

Mr. Marconi deserves the congratulations of all scientific men for the singularly able and ingenious manner in which he has brought wireless telegraphy to a practical issue.

Our thanks are due to Mr. Marconi and to Mr. Jameson Davis, the managing director of the Wireless Telegraph Company, for freely giving us information and permitting us to witness practical tests on the system.

INDUCTANCE IN TELEPHONY.

By W. MOON.

(*Concluded from page* 504.)

THIS condition being fulfilled, and E_m being constant, it will be found that the greater the difference between S and R when $R + S =$ constant, that the greater is the current in the secondary circuit. For if the value of "λ" be filled in equation (2) it can be written

$$y = \frac{E_m}{\sqrt{\frac{(S^2 + p^2 n^2)(R^2 + p^2 L^2)}{p^2 M^2} + p^2 M^2 + 2 R S - 2 p^2 L N}} \quad (4)$$

and if $p\,L$, $p\,N$ and $p\,M$ be written as resistances since they are to bear a constant proportion to R and S they may be written $p\,L = n\,R$, $p\,N = n\,S$, $p^2 M^2 = p^2 L\,N\,a = a\,n^2 R\,S$. Filling these values in (4) it reduces to

$$y = \frac{E_m}{\sqrt{R\,S \left\{ \frac{(n^2 + 1)^2}{n^2 a} + n^2 a + 2\,(1 - n)^2 \right\}}}$$

where the quantity in the brackets is a constant, and since the product R S is least at either end of the line, and greatest when $R = S$, it is evident that the nearer the transformer is placed to either end of the line the greater will be the current in the secondary circuit.

Moreover, at a particular point between the centre of the line and "E" the current in the secondary circuit would be equal to that in equation (3) where no transformer is used, and for any position nearer "E" than that point the current in (4) would exceed that in (3) in proportion to the nearness of the transformer to E. And this is the explanation of the use of the induction coil with telephone circuits, where the work done by the battery is much greater, and, consequently, the secondary current is much greater than if the microphone were used on the circuit direct.

The induction coils used with telephones are not of the closed magnetic circuit type. The primary current of a telephone induction coil is undulatory but not alternating, so that the inductances of such coils are single current inductances, and it is necessary to use coils with broken magnetic circuits having but little residual magnetism.

As the presence of a secondary circuit affects the impedance of a primary circuit, it is interesting to note the effect of sheathing such pieces of apparatus as indicators and transformers, as such sheathing acts in every way similar to a short-circuited secondary circuit.

If the value of "ν" be filled in the denominator of equation (1) the impedance of the primary circuit works out as

$$\sqrt{R^2 + p^2 L^2 + \frac{p^2 M^2}{S^2 + p^2 N^2}(2\,R\,S + p^2 M^2 - 2\,p^2 L\,N)},$$

from which it can be seen that the quantity in the brackets is positive when $2\,R\,S + p^2 M^2 > 2\,p^2 L\,N$, is zero when $2\,R\,S + p^2 M^2 = 2\,p^2 L\,N$, and is negative when $2\,R\,S + p^2 M^2 < 2\,p^2 L\,N$, and, therefore, that the current in the primary circuit is increased by the presence of a secondary circuit when $2\,R\,S + p^2 M^2 < 2\,p^2 L\,N$, and reduced when $2\,R\,S + p^2 M^2 > 2\,p^2 L\,N$.

Which of these two cases would result depends on the relative values of the resistances and inductances as well as upon the pitch of the voice. But generally it seems that it is not advisable to sheath telephonic coils with solid metals. And that if indicators are sheathed with iron to give them a magnetic circuit of less resistance that it would be advisable to split the sheathing from end to end to prevent it acting as a secondary circuit.

The inductance of a metal sheathing can be calculated from the measured inductance of a coil of wire occupying the same space and having n turns since the inductance of the sheathing would be $\frac{1}{n^2}$ that of the coil. And the mutual induction between the sheathing and the primary coil would be $\frac{1}{n}$ that of the primary coil and the coil occupying the space of the sheathing.

The cores of electro-magnets act as secondary circuits in the same way as an iron sheathing, and for this reason telephonic induction coils and transformers are provided with cores of iron wires oxidised on the surface. It is doubtful, however, whether the insulation thus procured is all that could be desired. A more efficient core for an induction coil can be made by winding iron foil up in a coil with paper insulation between each turn, as shown in fig. 5, when the straight line represents the iron foil, and the dotted line the paper.

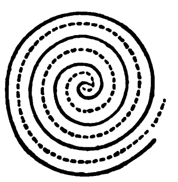


FIG. 5.

A transformer can be similarly made with iron foil in strips with paper insulation, as in fig. 6.

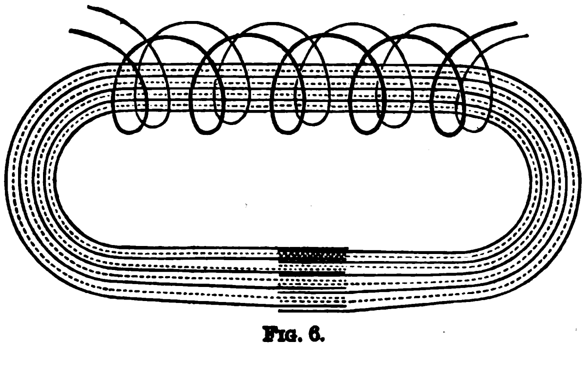

FIG. 6.

The advantage of these methods over the use of wire, is that apart from a better insulation, more iron can be got in the same space.

If, in a transformer in which the inductance of the two coils and the mutual inductance between them is equal, the inductance of the coils be separated from that of the lines by substituting $L_1 + M$ for L and $N_1 + M$ for N in equation (4) this equation reduces to

$$y = \frac{E_m}{\sqrt{\frac{(S^2 + p^2 N_1^2)(R^2 + p^2 L_1^2)}{p^2 M^2} + 2\,\frac{(R^2 + p^2 L_1^2)\,p\,N_1 + (S^2 + p^2 N_1^2)\,p\,L_1}{p\,M} + (R + S)^2 + (L_1 + N_1)^2 p^2}}$$

From which it can be seen that the greater M is made the nearer the current in the secondary circuit approaches

$$y = \frac{E_m}{\sqrt{(R + S)^2 + p^2 (L_1 + N_1)^2}}$$

In a tranformer in which $L N = M^2$ the current can be expressed in the number of turns of wire in the primary and secondary circuits. Let $L = n^2 K$, $N = n_1^2 K$, and $M = n\, n_1 K$. Then if these values of L, N, and M, be filled in equation (4) it reduces to

$$y = \frac{E_m}{\sqrt{\left(\frac{R\ S}{p\, n\, n_1 K}\right)^2 + \left(R \frac{n_1}{n} + S \frac{n}{n_1}\right)^2}}$$

where "K" is a constant depending on the form and size of the transformer, and R and S are the resistances of the primary and secondary circuits which are free from inductance except in the transformer itself.

The mean E.M.F. of a generator can be measured by comparing the deflection produced in a galvanometer by half a revolution of the armature, with the deflection produced by the discharge of a condenser.

If a condenser of capacity "F," and charged with an E.M.F. "e," be discharged through a galvanometer then

$$q_F = F\, e,$$

and the discharge from the generator

$$= q_G = \frac{\Phi\, n_1}{\omega} = \int_0^{\infty} \frac{e_1}{\omega} d\, t,$$

where Φ is the flux of force and n_1 the turns of wire of the armature, and "ω" the total resistance of the circuit. Hence the mean E.M.F. generated when the armature revolves n times per second is

$$E_m = 2\, n\, \Phi\, n_1 = \frac{q_G}{q_F} F\, e\, 2\, n\, \omega.$$

Two generators of which the E.M.Fs. were thus measured gave 16 and 26 volts respectively.

It is found that telephone receivers speak much louder when they contain a permanent magnet, than when they do not. The action of the magnet in the receiver can be thus explained:—

The pull of an element of the diaphragm in the direction of the magnet is $\frac{\beta^2}{8\,\pi} \sin \theta\, d\, s$, where β is the induction and θ the angle the lines of induction make with the diaphragm. Hence the pull on the diaphragm is

$$\frac{1}{8\,\pi} \int \beta^2 \sin \theta\, d\, s.$$

Assume this equal to Φ^2. Then when a current passes through the coil of the telephone the flux would be altered to $\Phi \pm \Phi_1$, and the pull to

$$(\Phi \pm \Phi_1)^2 = \Phi^2 \pm 2\, \Phi\, \Phi_1 + \Phi_1^2,$$

so that the alteration in the pull that determines the motion of the diaphragm would be $\pm 2\, \Phi\, \Phi_1 + \Phi_1^2$. Obviously Φ_1 is much smaller than Φ, so that the loudness of the speech is proportional to the strength of the magnetism of the permanent magnet.

If a soft iron core, instead of a magnet is used, Φ still represents its magnetism, that is, its residual magnetism, and hence the speech is not nearly as loud.

CORRESPONDENCE.

Hoisting Gear for Street Lamps.

With reference to the Davy hoisting gear which you described in a recent issue (p. 469), it would, I fear, be very difficult to carry the steel wire rope round the semi-circle of the carrier on small rollers, as shown in the drawings. To start with, how is one to get the rollers in position in the hole, and supposing that possible, not much space is going to be left for the two cables.

The makers must have early recognised this difficulty, as the sample lamp at Bath, which is referred to in your article, had the steel rope extending from the top of the post to the end of the carrier, just above the contact springs; a sort of short cut, which does not look so neat as when the rope is entirely hidden, but which is effective enough.

In the 84 lamps which the Electric Construction Company, Limited, are now erecting at Bath, the steel wire rope is simply allowed to slide on the inside of the tube of the carrier, and the cables are kept from fouling it by means of a sheet-iron partition, which is slipped into the carrier before it is wired; the two electric cables resting side by side on this partition.

The writer thoroughly tested the first lamp-post and gear for Bath, and found this arrangement satisfactory, the extra friction due to the steel rope rubbing on the tube being apparently very small in comparison with the total weight requiring to be hoisted. A test was also made to see what the life of a $\frac{3}{16}$-inch diameter steel rope would be under these conditions, and it was found that the wear after 10 years of service might fairly be assumed to be inappreciable. The diameter of the rope is really governed by the question of how large a winch can be got into the space at disposal inside the post. A $\frac{1}{4}$-inch diameter steel rope and a 3-inch diameter winch seem about right.

There are several minor improvements in these lamps for Bath, thus two pawls working at half tooth are employed instead of one, and merely pushing the raising and lowering handle home lifts the pawls out of gear by means of a cone. The handle is fixed to an aluminium hand-wheel, so that in lowering the attendant may use his hand as a brake against the rim of the wheel. The contact is slightly different to the one you described, and it was found advisable to introduce a ball and socket joint immediately above it to allow for slight swaying in a high wind.

There can be no doubt that this raising and lowering gear has come to stay, and great credit is due to Messrs. Davy and Davies for introducing it. The fact that when the lamp is lowered it is automatically cut off from the circuit acts as an additional safeguard, besides the double loop of cable which was required. With the old-fashioned type of lowering gear was an additional expense, very liable to foul and kink, and the cause of an extra drop in voltage.

Corner brackets are a bit troublesome to fit with the gear, especially when there is a shop-door or window immediately below; but for tramway poles (especially centre poles), which also carry arc lamps, the lowering gear will be very useful, because trimming lamps with an ordinary ladder is a trifle dangerous, on account of the vibration and the live trolley wires close by, whilst, on the other hand, the traffic generally prevents a truck ladder being wheeled into position.

Ernest Kilburn Scott.

Jerry Wiring.

I had hoped the day of jerry wiring was over. Unfortunately, it is not. The specimen sent herewith is a sample of wire which I yesterday took out of an installation. This wire, you will see, is fair outside bell wire. I might mention that a large portion of this wire had been run under the floors without any casing, in holes bored in the joists. When will fire insurance companies learn that it is advisable, from their point of view, to safeguard their interests?

In justice to South Shields, I must mention that the work was not done by a South Shields firm.

Jos. A. Jeckell.

Blasting.

The communication from Mr. Barnes, in yours of the 8th, is very interesting. The points he mentions to help guard against a repetition of the serious accident which arose while testing detonators are useful, but it suggests to my mind a farther consideration. Is it not a mistake to allow unskilled persons to test at all? The sensitive bridge of a low tension fuse is easily broken, and thus the fuse is spoilt; hence the necessity for constant testing. But with good, reliable, properly constructed "*high tension*" fuses this is never so—once made good always good. I think the lesson to be learnt is: Use a good high tension fuse which needs no testing. I speak in their favour with a wide experience of 25 years.

Frank Brain, A.M.I.C.E.

Referring to the testing of electric detonators, your correspondent of the 8th inst. is in order in stating that, had the operator not tried to test the high tension electric detonator fuses with the magneto, all would have been well; but it is useful to those concerned that some of the points should be more directly referred to.

It cannot be too widely known that high tension electric detonator fuses cannot be tested for continuity *at all* without almost certain explosion, as will be realised by the sectional sketch in page 9 of Nobel's explanatory pamphlet, "Electric Shot Firing" (of which copy is enclosed).

Low tension electric detonator fuses (page 10) are preferably tested for continuity with a single cell and galvanometer, and then at a safe distance, or with the detonators thoroughly shielded.

Electric blasting being a safe method, is becoming very popular, and it is most desirable that all who use high or low tension electric detonator fuses, should obtain from the company who make, or the agent who supplies the goods, some explanatory instructions, such as Nobel's issue to customers, and there need be no danger.

In high tension electric detonator fuses the ends of the wires, touching the fulminating mixture, are about ⅛th of an inch apart; it is, therefore, quite evident that they cannot be tested for continuity without the "arc" so formed firing the flash mixture, which in turn fires the detonating mixture.

In low tension electric detonator fuses the platinum wire bridge is continuous through the flash mixture, so that with a single cell and galvanometer one obtains a deflection of the needle, showing the circuit complete. As the electromotive force and current are so moderate, the platinum wire is not heated sufficiently to fire the composition.

In all matters pertaining to high explosives, the principal desiderata are a thorough understanding of the details, and the exercise of a little thought and ordinary care.

Nearly every mishap or accident is due to an omission or a commission of some kind on the part of the manipulator.

John Mackenzie,
Electrical Engineer.

The Welsbach Incandescent Electric Lamp.

It would, I think, have increased the definite information on this subject if Mr. Gibson in his very able article had given the claims of Dr. Auer von Welsbach's patent which has been laid open for public inspection, and the subjoined translation of same, though possibly not literally accurate, will probably be of service :—

Claim 1.—**Filaments for incandescent lamps, consisting of—**

(*a*) Osmium, or;

(*b*) Osmium with a percentage of other platinum metals, such as platinum, iridium, ruthenium, or;

(*c*) A core of osmium with a coating of thorium oxide, or;

(*d*) A core formed from an alloy of osmium with the platinum metals mentioned under 1 (*b*), or of these metals or alloys of same and coated with thorium oxide.

Claim 2.—A process for the production of the filaments described in 1 (*a*) and (*b*), wherein,

(*a*) Osmium or osmium compounds are metallically deposited on a thin metal wire (core) by the reduction of a volatile osmium compound such as the tetroxide in reducing gases, and this core afterwards volatilised by incandescence, or;

(*b*) Osmium or osmium compounds are repeatedly spread in thin layers on to thin metal wires (cores) using a cementing material if desired, and the metal wire (core) then volatilised by incandescence, or;

(*c*) Osmium or osmium compounds are electolytically deposited on to a metal wire (core) and this core afterwards volatilised by incandescence.

(*d*) Osmium or osmium compounds in pasty form are repeatedly spread in thin layers on a vegetable or animal fibre (using a cementing material if desired), and converted into osmium by incandescence.

(*e*) Osmium or osmium compounds are made into an emulsion with collodion, denitrated and incandesced.

Claim 3.—A process for the production of the filaments described in 1 (*a*), (*b*), (*c*), (*d*), for electric lamps wherein thin layers of thorium oxide are successively and repeatedly spread on to the filaments mentioned and incandesced after each coating and the process repeated until a dense casing of thorium oxide has been formed on the filament.

In regard to these claims, as far back as 1878 (No. 5,306), Edison patented a filament made of platinum, platinum-iridium alloy, or other metal, which fuses at a high temperature, and is pyro-insulated by being coated with a metallic oxide, such as lime or magnesia, cerium or zirconium, which is not injured by a high degree of heat, and in a subsequent patent (1879, No. 2,402), he mentions the use of wire so coated in a vacuum, whilst in 1888 (No. 2,438) Mr. Langhans described thorium oxide as a filament for an incandescent lamp, and the coating of wires electrolytically with this material is also described by him in No. 23,137 of 1895.

The impregnation of carbon filaments with salts of the platinum group of metals is frequently the subject matter of patents between the years 1878 and 1892.

H. E. Moul.

Rubber Cables.

In connection with the late scare and damaging statements made concerning the behaviour of rubber-insulated cables at Burton-on-Trent, it would no doubt interest your readers to know that, according to the abstract of accounts for that undertaking published in one of your contemporaries in 1896, the cost of repairs and renewals of mains was only £15, and in 1897 on a capital expenditure on mains of £14,335, the cost of repairs and renewals for the year was only £16.

Wm. E. Gray,
Electric Light Department, Silvertown.

"Note on Condenser Shunts."

Owing to my own omission of certain words in my rough manuscript, the final paragraph in the "Note on Condenser Shunts" in the last issue of the Electrical Review is ambiguous. May I be allowed to supply the words omitted by me?

"The above diagram shows how an ordinary quadrant pole-reverser may be used either for Gott or for Thomson mixing connections. For the latter the sliding contact is direct to earth, and G with make-and-break key inserted between either of the capacity quadrants and earth, 1 and 2 being plugged for charge, and 3 for mixing."

E. Raymond-Barker.

April 15th, 1898.

MUNICIPAL ELECTRIC LIGHTING.

An interesting and instructive paper on "Municipal Electric Lighting" was read by Mr. W. C. C. Hawtayne, consulting engineer, at the Bishopsgate Ward Club recently. There was a large and influential attendance of members, including the chairman of the Watford Electric Lighting Committee, Mr. A. E. Pridmore, Mr. H. H. Richardson (solicitor to the Watford Ratepayers' Association), and many others.

Mr. Hawtayne's paper struck at the root of the whole question in the first paragraph, "who are the proper persons to undertake the work, local authorities or private companies?"

Beginning with a short history of the introduction of the dynamo, arc lamps and incandescent lamps, giving the several dates on which they made their advent, Mr. Hawtayne passed on to the time, only a few years ago, when the business men put their heads together and the voice of the promoter was heard in the land. To awaken interest in the new industry, the 1881-82 exhibition at the Crystal Palace was held, and many for the first time were able to see for themselves what could be done, and the great possibilities of the electric lighting in the future, and no difficulty was experienced, when batches of companies were floated, in obtaining money, for, to use the words of the author of the paper, "the general public went electricity mad."

Many companies immediately obtained provisional orders from the Board of Trade to supply electricity in the larger towns, and a table is given, which we reproduce below, of the provisional orders granted in 1883.

—	Granted.	Revoked.	Still in force.	
			Companies.	Local authorities.
1883	69	62	...	7
1884	4	4	...	...
1885	...	...	...	...
1886	1	...	1	...
1887	...	...	...	...
1888	...	...	...	...

In 1888, a new Act of Parliament which eliminated most of the drawbacks of the Act passed in 1882, had the effect of resuscitating the business of town lighting in 1889, when it was in the hands of the true friends of electricity supply, and the progress which has taken place since then is apparent on every side of us.

In 1889, nine companies obtained provisional orders and only one local authority; last year 42 local authorities and only eight companies, and only one of the companies' orders were for a new undertaking. These figures are at last convincing of the soundness of the business of electricity supply.

In 1890 the total number of 8-candle-power lamps supplied from central stations was under 200,000 in London, and in the provinces *nil*. In 1897 London had no less than 1,831,000, and the provinces 2,130,000. In London companies supply nearly 1,700,000 and the local authorities less than 150,000, whereas in the provinces companies only supply 600,000 and the local authorities 1,600,000.

These figures speak for themselves. It is not to be expected that local authorities will exploit a new industry; this must be done by companies interested in that particular industry. When it is demonstrated that the business is sound and contains no element of risk, then is the time that local authorities step in, and this is what has happpened. London is no doubt suffering, especially in the City, through what may be called their throwing away of a chance in allowing companies to secure the orders, but we think, for the reason given above, it was absolutely necessary for companies to exploit the new industry, and where could this be done better than in London? Moreover, a great many orders secured by companies were orders obtained simply by manufacturers of electrical machinery, whose members were also members of the various companies. This served a double purpose, namely, provided a market for their electrical wares and demonstrated the utility and sound commercial nature of the industry. Manufacturers have benefited by the change in the enormous amount of business done, and perhaps the only individual who has suffered by the action of the local authorities is the company promoter, and who cares for him?

Mr. Hawtayne gives a long list of reasons for municipalisation, many of which were advanced by the Town Clerk of Douglas, Isle of Man, in a report compiled by him some time ago. They are so strong and clearly stated that we venture to reproduce them here:—

"1. It is generally admitted that a municipal authority can borrow the necessary capital for the initial outlay under more favourable circumstances than can be done by any private company.

"2. By municipalisation the capital applied to the purpose would not be increased by promotion expenses, or by the result of early failures, as is the case with so many companies.

"3. Electric light can be supplied by a corporation at a price so as to be profitable; less than that which would be charged by a company, because the latter must charge a price sufficient, after payment of all working expenses, to provide a good dividend for its shareholders.

"4. By municipalisation the corporation would simply require to make a sufficient profit to pay the interest on the amount of borrowed capital.

"5. Where the installation is carried out by the corporation, it is not necessary to increase working expenses by payments to directors for administration, and consequently municipalities can manage more economically than companies.

"6. If the business which would accrue should be so profitable as to be greater than the interest required for money borrowed, this additional profit might not only be applied with advantage to the reduction of the rates, but also towards the very large expense which would be incurred in lighting the public streets and thoroughfares.

"7. In the event of the corporation deciding to allow a company to undertake the installation, the first step of the company—assuming that the conditions imposed by the Imperial Parliament would apply locally—would be to select a compulsory area, limited in extent, but which would certainly comprise the choicest portion of the town, from an electric lighting point of view. Ratepayers within the limits of this compulsory area would be able by the use of the electric light to make their places of business more attractive, to the detriment probably of the ratepayers outside, who could not demand a supply for two years, and could then only obtain it under onerous conditions of guarantee, &c.

"8. Where installations are in the hands of companies, the progress and growth of the undertaking is necessarily slow. Shareholders naturally believe in quick returns, and insist upon immediate and good dividends as the precursor to any contemplated enlargement of the capital account. From the beginning business is cramped and really obstructed for want of capital, with the inevitable consequence that the unfortunate ratepayers in the outside area are left out in the cold.

"9. A corporation can afford to take broader views than a company, and in the event of the business being sound as a commercial concern justifying extensions, the object of the corporation would be to develop it on an extended basis as expeditiously as possible. The municipality could afford to provide capital extensions without the necessity of waiting for a 5 per cent. or 6 per cent. dividend upon the work in the compulsory area, the principal aim, with due regard to permanent profitable results, being for a corporate body to extend the benefits of electricity supply throughout the whole of the borough.

"10. The corporation would be in itself a good customer in the direction of public lighting. The drawback to the electricity supply industry is that arising from the fact that the demand ceases almost entirely at bedtime, and economical working is greatly increased if the load can be continued far into the night.

"11. Municipal authorities—Esau-like—in numerous instances, have sold their birthright by sacrificing the monopoly in gas and water, and the same blunder, it is contended with reason, would be perpetrated by sanctioning the creation of a similar monopoly in the hands of a company providing an installation of electric light.

"12. Experience demonstrates that ratepayers as a body will support an undertaking in which, as ratepayers, they are personally interested as predominant partners more readily and more extensively than a concern which they naturally look upon as a private monopoly worked for private gain only.

"13. The most important reason, however, which is urged is that by retaining the manufacture and supply of electrical energy in its own hands, the corporation retains for itself the entire control of the whole of the industry, while it at the same time applies to the use of the ratepayers a system of sanitation as beneficial to the public as the system of water supply or that of drainage.

"14. Because with increased demand the cost of production will become infinitely less while the price charged to the consumer can remain the same if desirable.

"15. That with reduced charges the demand is bound to increase. At present electricity has been supplied for little else than lighting, but great advances are being made in electric cooking and heating, and, of course, in motive power work, and I might safely say that within a few years' time every tramway in the kingdom will be driven by electricity. Now the most serious bar to a reduction in the price of supply lies in the fact that with an ordinary lighting load the plant is only working at its maximum load, that is its highest efficiency for about two hours per diem, during the remainder of the day the standing charges are going on and the sales are infinitesimal. Think what a difference there will be when electric cooking and heating are in favour and tramways are working for 15 hours a day.

The traction load will in most of the large towns be larger than the lighting load, and many tramway companies have already arranged with local authorities or supply companies to take their supply of electricity from the lighting station, in some cases the price to be charged not to exceed 1½d. per unit.

"16. That the municipalisation can do their public lighting at cost price. Some local authorities say that they will light the streets at cost price, neglecting all depreciation and management expenses because they say we are making a profit out of our private customers. 'The works are there to supply them whether we supply the public lamps or not, so we will only charge the ratepayers for public lighting, the extra cost involved by keeping the plant running a little longer and for the extra fuel, &c., consumed and the upkeep of the lamps."

Mr. Hawtayne's paper should be read by every member of the councils in the different towns and cities where the question of electric lighting is being considered. Unfortunately sufficient thought is not always given by those gentlemen when considering this momentous question, perhaps on account of the lack of such useful information as the paper under consideration affords, and which is presented in a light and, in language free from technicalities, easily understood.

The question of electric traction for tramways is engaging the minds of local authorities who have established their stations, and this fact, combined with the lighting question, should awaken double interest in the minds of those who have the deciding for and against allowing companies to step in and secure orders which have the effect of keeping up the price and depriving the poor man of his light, for, undoubtedly, the electric light is the poor man's light, and we confidently think electric traction the poor man's brougham.

BUSINESS NOTICES, &c

Agency Notice.—We understand that Messrs. Gudgeon and Co., of 85, Finsbury Pavement, E.C., are the newly-appointed agents for Messrs. Flather & Son, electrical engineers, of Leeds.

Announcement.—Mr. G. Stegmann, of Clapham Junction, has taken larger premises at 45, St. John's Hill, Clapham Junction, where he intends opening electric light showrooms.

Catalogues.—Mr. James White, of Cambridge Street, Glasgow, has brought out a new price list of Lord Kelvin's electrical instruments, also other apparatus for central station and laboratory use. The list is bound in brown cardboard covers, is well printed, and a good enamelled paper is used, showing off the excellent illustrations to best advantage. Among the many instruments of which detailed descriptions are given, we observe the Kelvin standard direct-reading electric balances, standard watt balances, special standard ditto, Kelvin's standard electrostatic voltmeters of various types, dial central station voltmeters, recording ditto for direct currents, astatic recording ditto for alternating currents, Kelvin's ampere gauges, engine room wattmeter, testing set, Kelvin's electricity supply meter, Kelvin's continuous rheostats for current regulation, galvanometers, resistance coils, and Wheatstone's bridges, electrometers, &c. In the engineering and general apparatus section is Amsler's planemeter for determining the mean pressure in an indicator diagram, Thompson's indicator, tachometers and speed indicators, and pyrometers. The conditions and fees for Board of Trade instrument tests are given at the end of the catalogue.

Messrs. Fuller & Co., of 28, Bush Lane, Cannon Street, E.C., have issued new catalogues dealing respectively with telephones and fittings. The telephone list gives numerous illustrations, weights, prices, and code words of various telephonic apparatus and accessories. Portable telephones, wall and desk apparatus, extension bells, intercommunication boards, exchange switchboards, lightning arresters, safety fuses for protecting telephones from high tension currents, also diagrams of connections for systems of various dimensions are given in this list. The electric light fittings catalogue shows a variety of plain and ornamental brackets, some very neat designs in electroliers, standards, pendants, shop lighting fittings, ships' fittings, arc lamp-posts, and various accessories.

Electric Lifts.—The City and South London Railway Company has placed the order for the whole of the electric lifts required on their new Islington extension in the hands of the United Ordnance and Engineering Company, Limited, of London and Erith, with whom Easton, Anderson & Goolden, Limited, are now incorporated. Each lift will be fitted with their patent gear, and will be capable of carrying about 70 passengers, and the average stroke will be 72 feet. The current required for working will be supplied from the generating station of the railway company. This firm has recently adapted one of the hydraulic lifts on the Stockwell section of this line so that it is now worked by electricity. The United Ordnance and Engineering Company, amongst other work of this class, has in progress five electric lifts for the new Brighton Tower, three of them serving to the 80 feet level, and two to the top of the structure, which is over 500 feet high, the speed of the latter lifts being 300 feet a minute, and each carrying 30 passengers. They are also supplying to the Royal Agricultural Hall a large electric platform lift to raise two tons.

Electric Organ Blowing.—The new organ which is being put down at Lincoln Cathedral is being supplied with electric blowing apparatus by Messrs. Bergtheil & Young.

Extension Granted of the Parsons Patent.—Before the Judicial Committee of the Privy Council (present—Lord Watson, Lord Macnaghten, Lord Davey, and Sir Richard Couch) a petition was heard on 19th inst. for the extension of the term of letters patent dated April 23rd, 1884, granted to the Hon. Charles Algernon Parsons for an invention of "Improvements in rotary motors actuated by elastic fluid pressure and applicable also as pumps." Mr. Moulton, Q.C., and Mr. A. J. Walter were counsel for the petitioner; the Attorney-General and Mr. Sutton for the Crown. It was stated, says the *Times* report, that the invention related to machines known as steam turbines. Prior to the date of the petitioner's letters patent no steam turbine was, so far as the petitioner was aware, in practical use within the realm. Many persons had endeavoured to employ the velocity of steam generated in a boiler for the purpose of causing constant revolution in one direction of moving parts without the use of the reciprocating apparatus commonly in use in engines actuated by steam, but, so far as was known to the petitioner, no practical machine had, at the date of his patent, been devised which would enable steam to be used in this way. At the time when the petitioner first devoted his attention to the subject of steam turbines no one had worked out the conditions essential to the manufacture of a practical turbine which would be capable of working with an efficiency in any way comparable to the efficiency of steam in engines of the reciprocating type. The petitioner, after many experiments and long and exhaustive research, was enabled to produce a practical steam turbine, and to lay down the conditions essential to the successful working of such a turbine. In order to do this the petitioner had to practically and theoretically work out the proper relations between the velocity of the moving parts and the velocity of the issuing steam acting upon them, and by a system of alternate rows of fixed and moving blades he was the first to devise a working machine and to proportion the parts of the machine so as to produce a practical working turbine. The high speed at which, in order to obtain the best results, it was necessary to run the moving parts rendered it essential that bearings of a novel description should be invented, the bearings being provided with a certain amount of elasticity, so that the moving parts would rotate around their centre of gravity, or principal axis, instead of around their geometrical centre or axis, so as to prevent vibration and shaking. The petitioner had also been able to eliminate one of the great difficulties attaching to steam turbines known as the thrust. In introducing the invention, the greatest opposition was encountered from engineers, engine builders, and others, and so little was known of the practical value of steam turbines at that time, that it was generally believed, in the engineering world, that no steam turbine could be constructed whose efficiency would approach the efficiency of the ordinary reciprocating engine. Many turbines constructed upon the principle of the invention were, however, now in use for the purpose of driving electric lighting and other machinery, and the public appeared now to have recognised the merits of the invention. Evidence was given as to the great merit of the invention. Machines made in accordance with the invention were now being largely adopted, and were being bought all over the country. One of the machines had been fitted to a vessel 100 feet long, which attained a speed of 34½ knots, a speed which it was believed would be increased if the machines were fitted to larger vessels.—Lord Kelvin was called as a witness in support of the petition, and said there was no practical steam turbine before the petitioner's. The petitioner's invention gave, for the first time, a practical steam turbine. There was a great future for steam turbines. The petitioner's invention had given very good results, and for many purposes it was going to supersede the reciprocating engine, and its application to ships was a very great step indeed.—Lord Watson said their Lordships would humbly recommend her Majesty to grant an extension of the patent for a term of five years, and they would state their reasons for coming to that conclusion on a later day.

Langdale, Hallett & Co. v. Russell & Lennard.—Before his Honour Judge Lumley Smith, Q.C., in the Westminster County Court on Wednesday, the plaintiffs, builders, of 122, Brompton Road, S.W., sued defendants, formerly in partnership as electrical engineers at 135, Victoria Street, Westminster, for £24 5s. 10d. for work done at 41, Bedford Square in connection with making good the walls there after cutting them for defendants to put in electric fittings, they having the contract for the installation. Judgment was given for the plaintiffs.

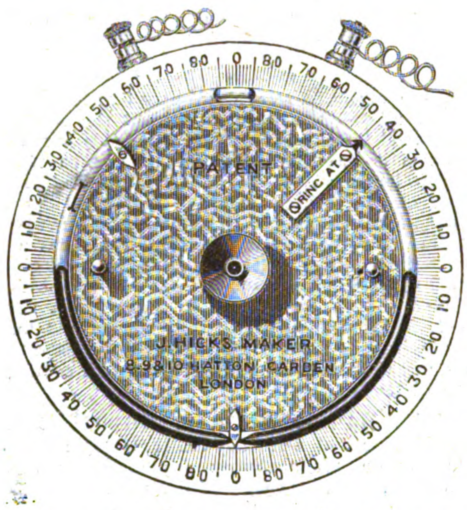
Liquidation Notice.—A meeting of the Electric Traffic Syndicate is to be held at 6, Old Jewry, E.C., on May 23rd, at 2 o'clock, to receive an account of the winding-up operations from Mr. Maurice Jenks, the liquidator.

Melbourne Working Men's College.—We have received a copy of the 1898 prospectus of this College, giving full particulars regarding the different subjects in which instruction is given, and photographs of some of the workshops and class rooms. Mr. W. N. Kernot is the instructor in the electricity department, and Mr. L. S. Daniel is instructor in telegraphy.

Police Electric Lamps.—A sub-committee of the Cardiff Watch Committee has instructed the head constable to report on the subject of electric lamps for the police.

The Shannon Electric Power Scheme.—So many erroneous impressions prevail with regard to this project, that Mr. W. T. Fuller, engineer to the syndicate, writes to a Dublin paper, giving a brief description of the scheme. Originally the desire was to utilise the various lakes of the Shannon River as storage reservoirs which should ensure a sufficiency of water for the power required during the summer; in short, it was desired to use these natural reservoirs to equalise the variable flow of the stream to a certain extent, ensuring a fixed summer quantity, greater than the normal, between Lough Derg and Limerick. In this scheme of storage Lough Allen was included; a certain volume of water would have been retained there to supplement the flow into Lough Derg when the quantity required from that lake exceeded the supply entering it at the upper end. This procedure was said to spell ruin to the fishing industry, and rather than force it Mr. Fuller advised the directors to revert to the use of steam during periods of drought, and to leave the summer flow untouched. Various objections have been raised to the company's proposals. The intention to develop a certain amount of power, with its necessary abstraction of a small share of the river, is considered to be generally objectionable. Side by side with that statement, however, "we are told," says Mr. Fuller, "that were we to take four or five times the amount of water, and develop four or five times the amount of power at once, we should deserve support; and, although the original proposal was to develop 5,000 H.P. only all the year round, and although the present intention is to develop 5,000 H.P. all the year round, and in addition another 5,000 H.P. during wet periods, it has been publicly stated that the capacity of the works has been decreased. These things must speak for themselves. I shall content myself with pointing out that even 10,000 H.P. is a very considerable factor in the industrial life of a community, and that the argument that no one should erect a water mill unless it takes the whole power of the river concerned, is a novel one. The intake and outlet of the power canal are separated by about a mile of river, containing fisheries. Down that river flows a volume of water, varying from one and a quarter millions of cubic feet per minute to one considerably smaller. The height of the flood water at Castle Connell frequently prevents good sport. Of that flood, it is proposed to divert a comparatively trifling amount and return it to the stream lower down. When the water is there, part of it will flow night and day, *viâ* the canal; when it isn't there, the generators will be steam driven."

Ships' Clinometer.—We illustrate below Hicks's new patent ships' clinometer, which has been designed to register the exact roll of a vessel at sea, or when listing to port or starboard. The clinometer shown is made entirely of metal, and the acting part consists of a circular tube containing mercury, with a contraction in the lower part to avoid undue oscillation, and is fitted with electric connections so as to record any particular roll of the ship in the captain's cabin or other place. For instance, if the captain desired to be warned should his vessel roll as much as 45°, he would place the small metal pointer marked "ring at," with arrow attached, opposite that point, as shown in the illustration. This is done by slightly releasing the milled screw head in the centre by giving it a few turns to the left



and then turning the pointer gently by the aid of the brass pins until the plate "ring at" is opposite the 45° or other desired point, clamping the disc again by turning the milled head to the right. Should the vessel ever roll sufficiently to cause the mercury to reach this point, contact is instantly made, and a loud warning bell would be rung. The bell can be placed at any desired distance away from the clinometer. This instrument has also an index to record the greatest roll. To re-set the index, release the milled headed screw and turn the disc round as described above, but it must be turned sufficiently to cause the mercury to pass round the tube and drive the index back. If it is desired not to cause the bell to ring when the index is being set, contact is broken by removing one electric wire from the terminal, replacing it after the index has been pushed round. The small quantity of fluid shown on top of the mercury is creosote, which is placed there for the purpose of always keeping the mercury pure and bright.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The Beach Bathing Station is to be lighted by electricity at a cost of £170.

Ayr.—On the proposal of Mr. A. J. Fuller, the electrical engineer, 23 additional arc lamps are to be used for street lighting.

Bedford.—The Electric Lighting Committee proposes inviting tenders for a new sub-station, also a new engine room at the electricity works, and for a 10-ton overhead travelling crane; and further, for a 30 unit dynamo. Application is to be made to the Local Government Board for sanction to borrow a further sum of £5,400 for electric lighting purposes.

Belfast.—The Electric Committee have under consideration the public lighting of some of the principal thoroughfares, to be carried out when the new station is working, and have instructed the engineer to prepare a statement of the comparative cost of gas and electric light. The report for the first quarters' working of this year shows that the output is 55 per cent. greater than for the corresponding quarter of last year. The statement of accounts for the year ending December 31st, 1897, also shows the department to be in a prosperous condition, the lamps connected being equivalent to 21,000 8-C.P's., whilst the average price obtained per unit is 6·035d., with a total of 201,832 units sold.

Bromley.—Mr. Ernest Newton is to design the central station buildings for the Bromley Electric Light Company, the site chosen being approached from West Street. It is stated that £7,000 out of the £20,000 required has been subscribed, and that a gentleman has offered to subscribe the remainder provided he receives a seat on the board of directors, but the offer has been declined.

Camberwell.—The Vestry has adopted the recommendation of the General Purposes Committee mentioned in our last issue, and will not proceed with the proposed purchase of the undertaking of the County of London and Brush Company.

Cheltenham.—A new "set" has been erected at the generating station, and a preliminary run was made the other day with the arc lighting load before putting it on the actual service of the town. It stood the trial to the entire satisfaction of the engineers, and in the evening took up the greater part of the street and private lighting without mishap of any kind. The new set consists of a Belliss engine direct coupled to a Siemens alternator, and has a capacity of about 250 kilowatts. It is the sixth set, so far, laid down. Three were in running when the works were opened nearly three years ago, viz., two with a capacity of 33 kilowatts each, and one of 110 kilowatts. Since then two other sets have been added, each of 110 kilowatts, and the one now erected has a capacity exceeding these two combined. Another of a capacity equal to it is now on order, and will be delivered in time to meet next winter's load. The committee already has authority to order another set of 400 kilowatts capacity, when occasion requires. All the sets have the Siemens alternator, but while the first three are driven by Willans engines, those since erected are engined by Belliss, under contract with Messrs. Siemens. The new set should have been in place before Christmas, but delivery has been delayed until now by the engineers' strike.

Colwyn Bay.—At the last District Council meeting the surveyor produced plans and specifications for the contract for lighting the promenade with electricity. He had every reason to believe that if tenders were advertised for at once the scheme might be completed by August 1st. Mr. W. Davies was inclined to believe that the town stood in as much need of electric lighting as the promenade. It was agreed to advertise for tenders forthwith.

Mr. Clirehugh has approved of the Ivy Street site.

Dewsbury.—We hear that for the post of borough electrical engineer there were about 60 applicants.

Dublin.—The Town Clerk asked the Corporation for instructions regarding the recommendations set forth in the report of the committee of the whole house relative to the proposed new electrical station at the Pigeon House Fort. The Corporation, after considering the matter, passed a resolution referring to a committee of the whole house to consider the entire question of the new station, the question of site, and also submitting the question of the station and scheme to the best electrical experts for advice; to suggest methods of raising the necessary money for erection and equipment of a station to supply current for lighting the entire city; to advertise for tenders for carrying out the work, and report thereon.

Dumfries.—The Provost's Committee of the Town Council is considering the question of electric lighting.

Ealing.—The Clerk has reported that now, at the end of the first three years of the Council's working of the electric lighting undertaking, 15,209 lamps had been applied for, and of these, 14,495 had actually been connected. The original estimate was for 5,000 lamps within the first three years.

Edinburgh.—The Lighting Commiteee has again considered its previous recommendation regarding the lighting of a number of additional streets—which recommendation was not approved by the Council—and has resolved to adhere to its proposal with a slight modification.

Hackney.—There is much dissatisfaction expressed locally at the unreasonable way the Vestry has been playing with the electric lighting question during the past few years, and ratepayers are beginning to feel that the Vestry is unable to settle matters satisfactorily by itself. Therefore the ratepayers requisitioned for a special meeting of the inhabitants, and this was held on Monday, the chairman of the Vestry presiding. The meeting passed, by 500 votes to 3, a resolution to the effect that the Vestry should keep the provisional order in its own hands. Mr. Henry Hulland, the chairman of the Electric Lighting Committee, argued that the Vestry could re-purchase the order at the end of 12 years as a going concern, and that if the proposed scheme was carried out the company would collect the house refuse to be consumed at the generating station and save the parish £5,000 a year. The prices to be charged by the company in Hackney would be considerably lower than in other London districts.

The Vestry met on Wednesday to receive the report of the Electric Lighting Committee, which recommended the transference to a company. In the heated speeches various charges of "treating" and corruption were made, and the matter was adjourned until after the next elections.

Holborn.—The Clerk of the Board of Works reports that, for the purposes of electric lighting, it is proposed by the Board of Trade to divide the district, one company to have the part south of Holborn, and the other the north part. A resolution was passed that the Board of Trade be informed that the Board of Works is still of opinion that both companies, who were now applying for permission, should be allowed to come into the district.

(*Continued on page* 549.)

ELECTRIC LIGHTING AND INSURANCE.

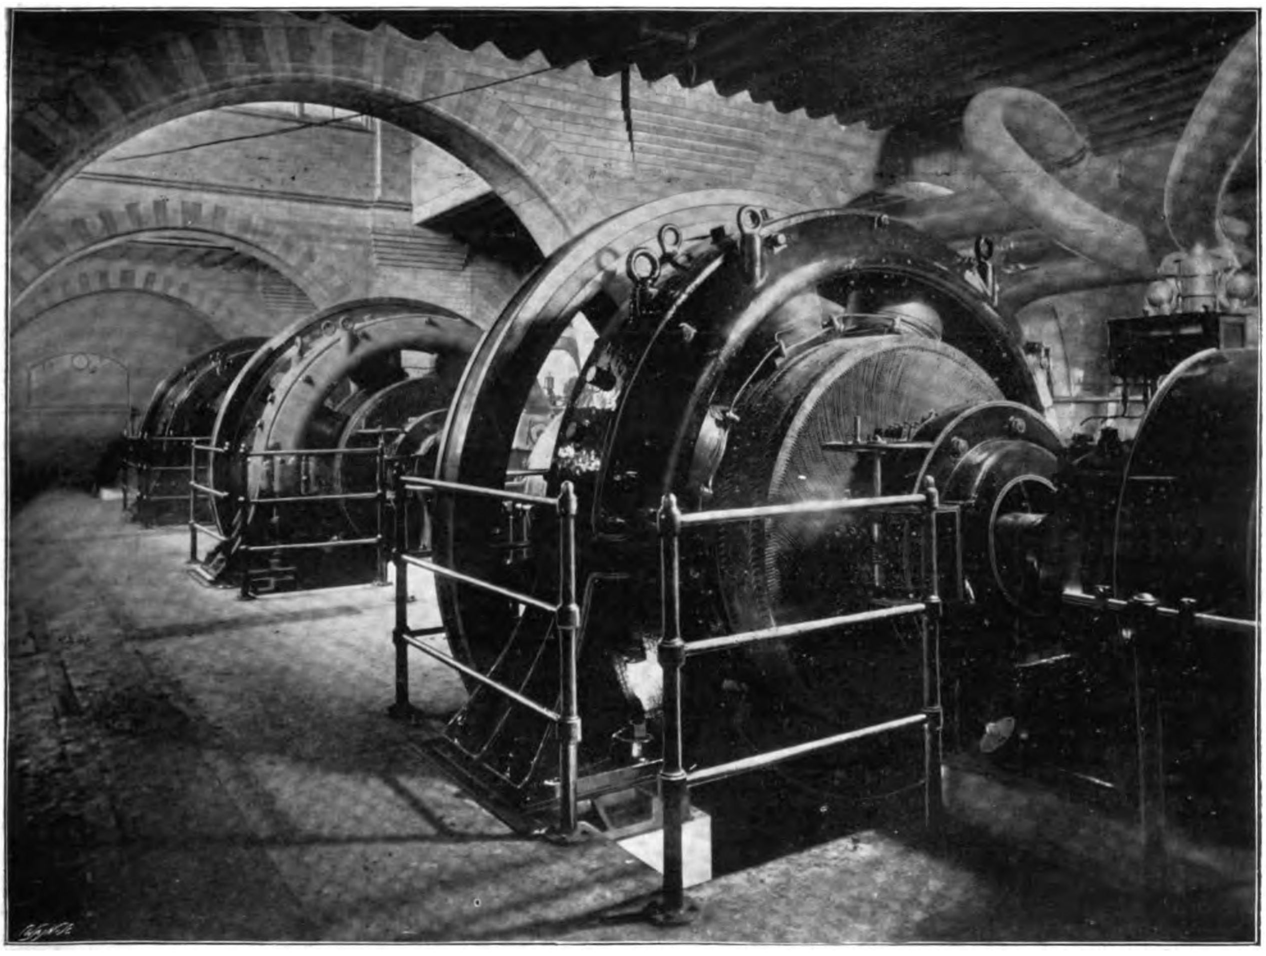
PROBABLY one of the most important, if not the largest private electrical installation in the country, is one that has been recently completed at the offices of the Prudential Assurance Company by Messrs. Drake & Gorham, with Mr. J. Landon in charge of the works. Some idea of the magnitude of the plant will be gained from the illustrations and the following description.

The Prudential Assurance Company have, during the last few years, been extending their premises to a great extent; whole streets are being pulled down to make room for these extensions, which seem to be never ending. One is almost sorry to see such famous localities as Furnival's Inn rapidly disappearing, but the demands of life insurance seem to be inexorable.

and Gorham, who have now completed the plant, have adopted slow speed dynamos, running direct between two horizontal coupled engines.

Each set consists of one dynamo and two single cylinder engines, weighing 60 tons, the weight on the main bearings being 22 tons. The dynamos have eight poles, the magnets being bolted to a steel ring 10 feet 5½ inches in diameter; the armature itself is 6 feet in diameter; the commutator has 360 segments, and is 3 feet in diameter, the revolutions being 85 per minute. A special pit is arranged beneath the commutator to enable the attendant to adjust the brushes. The weight of the armature and crankshaft is 15 tons, and there is a fly-wheel 12 feet in diameter, to ensure steadiness in running. There are three sets of this description, each of 184 kilowatts, and two smaller ones for light load.

The brush gear of the large dynamos is in some respects similar to that of the electric lighting dynamos employed by



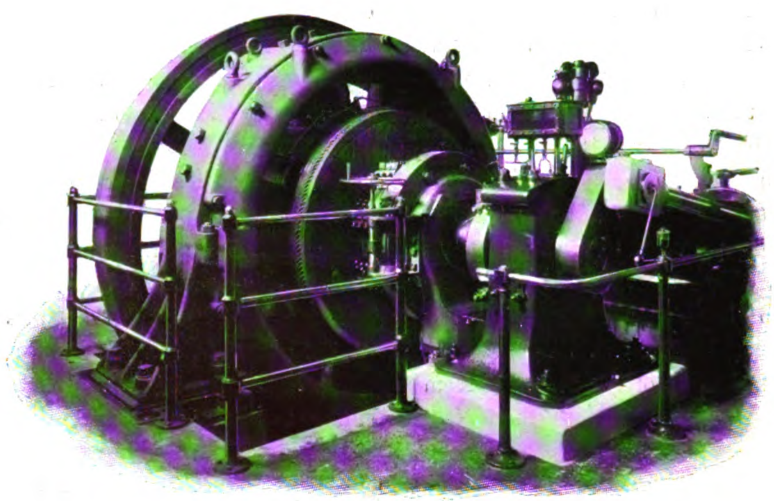
GENERAL VIEW OF DYNAMOS AT THE PRUDENTIAL COMPANY'S OFFICES.

The growth of the Prudential Assurance Company is probably one of the most remarkable features in the history of life insurance, and the alterations in the methods of lighting afford a faint indication of the increase in the business of this company.

It has been necessary to entirely re-model the electric light installation which Messrs. Drake & Gorham originally designed, the old plant having worked without intermission for 10 years. The policy which has been found so successful in central station work of turning out less efficient machinery and replacing it with modern plant of higher efficiency has been adopted in the present instance; in fact, the whole of the apparatus is new from beginning to end. Messrs. Drake

the Great Eastern Railway Company for lighting Liverpool Street and adjoining stations. There are 24 brushes arranged in eight groups of three brushes, the groups being alternatively positive and negative. The positive and negative groups are connected to copper rings carried in the main bearing of the armature. A hand-wheel and gear enables the position of the brushes to be readily altered as required, and gives a wide range of adjustment. Connection between the dynamos and the switchboard is made by means of rubber cables carried in earthenware pipes laid underground.

In accordance with the above proposal, engines to work up to 350 B.H.P. were specially constructed by Messrs. Marshall, Sons & Co. They are of the well-known coupled high pressure type, with 18 inches cylinders × 36 inches stroke. The steam admission gear is of the Proell type, and the exhaust gear of the Corliss type. A central governor controls the automatic gear for each pair of engines. The smaller engines are of the vertical type, one having cylinder of 16 inches × 16 inches stroke, the other 12 inches cylinder × 14 inches stroke. The portions of the dynamo were obtained from Messrs. Crompton & Co., and erected by Messrs. Drake and Gorham *in situ*. This particular size and arrangement has proved so satisfactory, that similar steam dynamo plants have since been constructed. The steam is supplied by five Cornish multitubular boilers, 24 feet long and 7 feet 7 inches in diameter, supplied by Messrs. Marshall, Sons & Co.; they work at a pressure of 100 lbs. through a duplex 11-inch wrought-iron steam main. The exhaust steam is utilised for heating purposes in the building.



One of the Large Machines at the Prudential Company's Offices.

The original design of main conductors for the distribution of the current has proved to be so successful that it has been extended. This consists of bare copper strips suspended from insulators on the walls of the building outside the area. There are many tons of mains on the walls. In most cases they simply run from bottom to top, entering the building at each floor, so that the appearance is extremely neat. The main distributing board is fitted with Messrs. Drake and Gorham's patent spring contact switches and Kelvin measuring instruments.

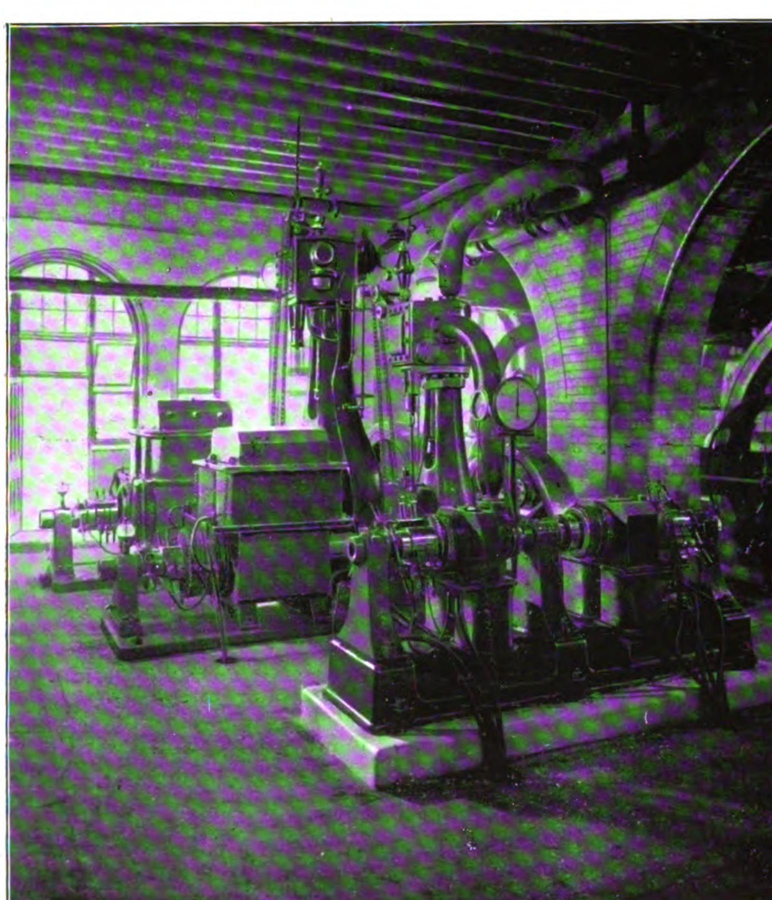
Practically the board is divided into two, positive and negative. On the positive board are three main switches for the three large dynamos, with fuses and ammeters connected to the main omnibus bar. In addition, are 14 switches and fuses which control the circuits into which the system is divided.

The negative board contains the negative fuses of the 14 distributing circuits and the main negative fuses of the large machines. The ammeters, switches, and fuses of the two small dynamos are also on this board, as well as the discharge switch of the battery.

We have already mentioned that the distribution is effected by means of 14 circuits, each of which is arranged to carry 300 amperes or practically 500 lights. Tappings from the main conductors are made on each floor, and at this point a sub-distribution board is arranged which is provided with a double pole switch and double pole fuses.

In spite of the work of the Prudential Company being chiefly confined to the daytime, it is necessary to provide a supply for the complete 24 hours. The light load demand during working hours is met by the smaller machines, but the all night supply is furnished by a large battery of accumulators.

The accumulators manufactured by the D.P. Battery Company are of the new central station type, and have several novel features, one being that the active surfaces of the positive plates are arranged facing one another on the inside of the plate, thus exposing a very large surface to the negative. Although these plates are cast in one piece, they may be described as being built up of a number of narrow plates facing one another, with ample space for acid and electrolytic action between the whole, forming one plate. Now, in an ordinary plate for every inch in width there would be 9 inches exposed, this being the height of the plate, but here we have in the width of 1 inch three strips, each 1 inch deep, having, therefore, six times the surface exposed, or 54 square inches. This plate, patented by Messrs. Drake and Gorham, has been thoroughly tried by the D.P. Battery Company for the past two years, and machines are now being put down to deal with the large demand that has already arisen.



The Light Load Plant at the Prudential Company's Offices.

In order to enable the machines to be wound for 100 volts instead of 130, and to permit of the battery being charged from the omnibus bars, a booster has been erected which raises the charging current to the necessary charging volts. The switchboard specially set apart for the accumulators and the motor generators is furnished with double pole switches for charging the battery, *i.e.*, on the generator side of the booster, and on the motor side, in addition is a 500-ampere charge and discharge regulator. This board is, of course, only used for charging, the discharge circuit being broken by a switch on the negative board.

The plant, with one set in reserve, is capable of dealing with 6,500 lights of 16-C.P. (equivalent to 13,000 8-C.P. lamps), a portion of which are fixed, and the remainder are being put in as the building proceeds.

The Boilers at the Prudential Company's Offices.

Owing to the steam being used for a pneumatic arrangement for sending messages from one part of the building to the other, for pumping, heating, and other purposes, it has been impossible to determine the actual figures as regards working cost, but the rough tests made have shown the result to be very satisfactory in every way.

The whole of the above work has been supervised on behalf of the Prudential Assurance Company by Mr. G. Bailey, of the Surveyors' Department.

Looking back upon the time when the Werdermann or Joel semi-incandescent lamp was first tried in the Prudential Offices, the present installation enables one to fully realise the progress which has been made during recent years in electric lighting, and Messrs. Drake & Gorham may be congratulated upon having erected a plant which for proportions and perfection cannot be surpassed in private supply. To Mr. Richardson, secretary to the company, high praise is also due for his indefatigable efforts to secure the best and most up-to-date arrangements for the colossal enterprise with which he has so long been associated, and with which he must feel eminently satisfied.

THE ELECTROLYTIC REFINING OF LEAD.

By SHERARD COWPER-COLES, M.I.E.E., A.M.I.C.E.

Lead, when recovered from its ores by smelting, is obtained as a crude metal, the so-called work lead, which has to go through a refining process in order to obtain soft or market lead. Work lead is obtained either by roasting reactions, by reduction, by roasting and reduction, or by the precipitation process. Refining is effected either by oxidation after fusion, or by electrolysis. Lead is never obtained pure when smelted from the ore. It is almost always alloyed with all the other metals contained in the ore itself. Apart from the fact that the useful properties of the metal are affected by these other metals, it is, of course, advisable for economic reasons to recover the precious metals present, such as silver One of the first processes worked on a commercial scale for the electrolytic refining of lead by electrolysis was that of Keith. In this process the crude or work lead is melted at the lowest possible temperature in iron kettles, from which it is tapped into moulds. The anodes thus produced are fastened to metal rods by suitable clamps, and enclosed in close-fitting bags of coarse muslin. The electrolysing cells are made of wood or iron; the cathodes are thin metal plates attached to rods in a similar manner to the cathodes. The electrolyte is composed of lead sulphate dissolved in an aqueous solution of acetate of sodium; it is made by electrolysing with lead anodes a mixture of 1½ lbs. of acetate of sodium, 2¾ ounces of sulphuric acid, and 1 gallon of water, and is heated to 38° C. The sulphuric acid attacks and the acetate dissolves the lead, zinc, and iron of the anodes. The zinc and iron, being electro-positive to lead in the liquid, are less easily reduced to metal and accumulate in the solution, and when dissolved in considerable quantity are, to some extent, deposited as oxide on the cathode, the current density employed being about 1·86 amperes per square foot. The lead which is deposited on the cathode is crystalline in form and separates continually from the plates, a space being left in the cells for its accumulation. When the anodes have been dissolved, the bags suspended from their supporting rods are carried to a reservoir and the residual solid matter from the plates is washed and returned to the melting kettles. The slimes suspended from the wash water are allowed to settle, the water is drained off, and the residue filtered. The slimes usually contain antimony, arsenic, silver, copper, gold, and iron. A process that has been recently tried on a commercial scale is that of Tommasi. In this case, the electrolyte is the double acetate of lead and potassium (or sodium) the anodes are crude argantiferous lead, and two of these are opposed to a copper or aluminium alloy cathode, which is in the form of a disc rotating at the rate of from one to two revolutions per minute. These discs are about 10 feet in diameter and three-quarters of an inch thick and are half immersed in the

The Switchboard at the Prudential Company's Offices.

liquid. At the upper part are scrapers which serve to detach the small spongy crystals of lead which form during electrolysis. The crystals when removed fall into channels which convey them to a sieve of wire gauze where they are drained and washed, the wash water being concentrated by evaporation to 20 Baume (sp. gr. 1·256) and used again in the electrolyte. The lead is then compressed and mixed with 2 or 3 per cent. of charcoal powder and fused. The silver, with most of the arsenic and antimony, is separated at the anode, and is collected in trays to be fused subsequently with sodium nitrate and a little borax, by which the silver is separated from the arsenic and antimony.* The cost is estimated by the inventor at from 8 to 10 francs per ton of lead when steam power is used. When lead acetate is used as an electrolyte, the resistance is found to be lowered, which is probably due to the prevention of lead peroxide deposits upon the anodes, which must be at the expense of the organic substance itself, which becomes slowly and surely oxidised. The products of the oxidation of acetic acid are carbonic acid gas and water, which are of no intrinsic value. This being the case the acetic acid becomes an expensive electrolyte as it has to be constantly renewed. The lead peroxide formed at the anode is reduced by a portion of the organic acid to oxide, which then dissolves in the acid and becomes finally reduced to metallic lead at the cathode. The impurities present in the crude metal and the oxides on the face of the anodes are usually bad conductors of electricity, and, if they do not become detached from the anodes, they form an insulating coat over a large portion of the anode surface. The natural consequence of this is, that the current passes mainly through those parts of the plate that remain freely exposed, and so the current density becomes greatly increased at those portions, with the result that the anode is rapidly riddled with holes. The addition of fluid carbonic acid when mixed gradually with sulphuric acid and digested for some time at a temperature of from 50 to 100° C. easily converts it into cresole sulphuric acid, which is soluble in water, and is capable of forming soluble salts with lead. These salts have been successfully used for the deposition of lead.

Maxwell Lyte has suggested converting the lead into chloride and electrolysing it in the molten condition. Crude lead is fused and oxidised by a blast of air in a converter, the oxide is then stirred with hydrochloric acid in earthenware vessels until it is converted into chloride. Any silver compound associated with the lead, salt, or oxide treated, is chlorodised and is extracted from the mass by the application of strong hydrochloric acid or brine.

MEASUREMENT OF THE EFFICIENCY OF CONTINUOUS CURRENT ELECTRIC MACHINES OF ALL POWERS.†

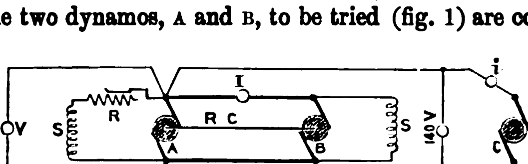
By P. DUPUY.

We know what difficulty is experienced in the workshops where electrical machines are constructed, in determining accurately the efficiency of these machines.

The brake methods are no longer employed, on account of their want of accuracy, and the different sources of error arising from their employment. Other well-known methods require mechanical appliances and rheostats, that are not often available when the power of the dynamos to be tried attains a certain importance. The method that we are about to describe has not yet been proposed, we believe, and we think that it may be of some interest to machine constructors.

This method necessitates the use of two similar machines.

The two dynamos, A and B, to be tried (fig. 1) are coupled



I = 1,000 amp.; i, 160 amp.; V, voltmeter; S, shunt; R, exciting rheostat; R C, rigid coupling; V, voltmeter 140 V; C, 3rd machine 200 amp. 140 volts.

in parallel by means of conductors of short length and considerable section, so that we need not take into account losses of energy from this cause. The two dynamos have their armatures coupled rigidly by any system, a Raffard coupling, for instance, and the connections are arranged as shown in fig. 1.

We send into the whole arrangement the current produced by a third dynamo, C, the power of which need not be equal to that of the two first.

We will suppose that we have to try two machines of 140,000 watts, at 140 volts; it will be sufficient, for instance, to have for the third machine a power of 28,000 watts, or 200 amperes, at 140 volts.

The rigid pair of machines to be tried begins to revolve; the excitation of one of them is then lessened, so as to break the electrical equilibrium existing before. Precisely at this moment, we must observe, one of the dynamos becomes a generator and the other a motor. The current resulting from this want of equilibrium is then made to give the normal output, or, in the case under consideration, 1,000 amperes. The two dynamos of 140,000 watts then work at their normal rate of 1,000 amperes at 140 volts, and it is evident that the losses are furnished by the third machine, and we have only to measure the output in amperes and in volts to get the total losses of the two dynamos. The total loss of one of the two dynamos being tested is equal to half the watts furnished by the third machine.

Working thus, we suppose that the efficiencies of the two machines are equal—which is not quite correct, as one of the machines is a generator and one a motor. This error, however, can be disregarded, as practically it only amounts to some thousandths, and, moreover, the hypothesis is used in other methods.

There is also, in this method, another source of error, which we will mention, although it is of scarcely any practical importance, especially in powerful machines.

In short, the watts furnished by the third machine representing the total loss, include the losses by the Joule effect, which should be expressed by $2\,R\,I^2$, and which are by

$$R\,(I - i)^2 + R\,(I + i)^2 = 2\,R\,I^2 + 2\,R\,i^2,$$

or an addition given by the term $2\,R\,i^2$. But we must observe that the resistance, R, is very weak in powerful machines, and that, moreover, this augmentative error is of an opposite nature to the one due to the above-mentioned cause, so that for both these reasons it is practically of no importance.

If we again take, as an example of the application of this method the two machines of 140 kilowatts, quoted above, we get, at the tension of 140 volts:

$$I = 1{,}000 \text{ amperes}$$
$$i = 160 \quad \text{„}$$

which gives a loss of

$$\frac{160}{2} = 80 \text{ amperes}$$

for each machine, or an efficiency of

$$\frac{1{,}000 - 80}{1{,}000} = \cdot 92.$$

As we see, this method is particularly applicable to the practical testing of powerful units; it has the advantage of being quick, and it only requires a very limited apparatus, the various appliances being found in all testing rooms of machine constructors. We think, therefore, that this is a very practical method, and, as such, we have thought it would be worth while to make it known.

Interesting Ceremony.—An interesting gathering took place recently at St. James's Hall, Manchester, at which over 1,100 guests assembled to celebrate the silver wedding and at the same time the coming of age of the eldest son of Mr. and Mrs. Isidore Frankenburg. Mr. J. Furness, on behalf of the employés of the Greengate Rubber and Cable Works, presented a handsome epergne, suitably inscribed, to Mr. and Mrs. Frankenburg, and a dressing bag to Mr. Cherton Frankenburg. Among those present were Alderman Sir W. H. Bailey, Alderman Hall, and the Town Clerk of Salford. Alderman Sir W. H. Bailey added his congratulation in a neat speech. We also may, perhaps, be permitted to join in congratulations, as Mr. Frankenburg has recently entered the electrical field as a manufacturer of insulated cables.

* The arsenic and antimony are oxidised to the maximum and unite with the soda to form scoria.

† *L'Eclairage Electrique.*

ELECTRIC LIGHTING NOTES.

(*Continued from page* 544.)

Horsham.—Warnham Court, Mr. C. J. Lucas's country seat at Horsham, is to be lit with electric light. There will be 300 lights in all, which will be supplied from the farm by a combined system of gas and petroleum engines, the power being also utilised for pumping and driving farm machinery of all kinds. A "D.P." battery of 106 cells of the latest type will be provided. The contract has been entrusted to Messrs. Drake & Gorham.

King's Lynn.—Prof. Robinson's report on the electric lighting question is before the Council, and it has been decided to apply to the Local Government Board for sanction to a loan of £30,000.

Kinning Park.—A Kinning Park (Scotland) Municipal meeting referred back a recommendation to apply for an electric lighting order, and the Committee will obtain further information.

Leyton.—The tenders received for the electric lighting extension plant have been referred to the Electric Lighting Committee. For the dynamos, tenders were submitted as follows:—Electric Construction Company, £854; T. Parker, Limited, £931 10s.; General Electric Company, £647 16s. 6d.; United Ordnance and Engineering Company, £761; India-Rubber and Gutta-Percha Company, £738; Laurence Scott & Co., £771; Laing, Wharton & Down, £732; Brush Electrical Engineering Company, £827 7s.; Johnson and Phillips, £716 15s.; Siemens Bros., Limited, £737; Paterson and Cooper, £736. Contract No. 2:—Crossley Bros., Limited, £1,900; Wells Bros., £1,707 6s.; Bilbie, Hobson & Co., £1,803 2s. For buildings: J. Haydon, £2,643 4s. 9d.; F. J. Coxhead, £2,594 15s. Mr. Coxhead's tender was accepted. For switchboards: J. White, £181 12s. 9d.; Bertram Thomas, £175 15s. 6d.; Laurence Scott and Co., £150; Laing, Wharton & Down, Limited, £157 10s.; Veritys, £153 4s. 9d.; Siemens Bros., £239 5s. Pea-nut anthracite is to be included in the next coal contract, and the grates of the present gas producing plant will be altered to suit the new fuel. From July 1st the charge for current for lighting purposes will be 5d. per unit for the first 1½ hours and 2d. per unit after, Wright's demand indicators being used.

London.—Mr. D. J. Ross, the City engineer, has issued a report on the works and improvements which have been executed in the City during the past year. He says that the number of arc lamps in lighting at the end of the year was 494. The question of lighting the side streets by electricity is still under consideration. The number of defective electric lamps observed during the last 12 months was 1,620. These returns are made to the Commission daily by the police, and the Electric Light Company is fined for each failure. Beneath the City streets now under the control of the Corporation, there exist at the present time about 2,360 yards, or one and a third miles of subway. The lengths of gas, water, and hydraulic mains, telegraph and pneumatic tubes, and electric lighting conduits laid in these subways amount to a total of 7¾ miles. The electric light and telegraph conduits contain about 424 miles of wires and cables.

Lowestoft.—The provisional order has been approved and granted by the Board of Trade.

Ludlow.—The Public Lighting Committee reported that 10 schemes were sent in by engineers, and that of Mr. J. S. Enright, of Kensington, has been awarded the first prize of £20 by the Council.

Mexico.—Further copies of the Mexican papers show that several more failures have arisen in connection with the electricity supply plant. On one occasion recently a number of the public streets were in darkness the whole night, and the Portales, Municipal Palace, and other buildings were in darkness for a considerable time.

Newcastle.—At a meeting of the special committee of the Corporation, held on Monday, it was decided to submit to the Council a proposition in favour of approaching the electric lighting and current companies, with a view to buying up their interest and plant.

Paris.—The Municipality has decided upon having all the principal roadways of the Bois de Boulogne lighted electrically.

Perth.—Mr. Gripper, managing director of Edmundson's Electricity Corporation, Limited, has written to the Perth Electric Lighting Committee stating that as the provisional order would soon be passed, he should be glad to meet the Committee as to the transfer of the electric lighting powers to his company. The meeting resolved that the Committee were not yet ready to take any definite step in this matter.

Port Adelaide (Australia).—Early last month the Mayoress laid the foundation stone of the electricity works which are being put down by the South Australian Electric Light and Motive Power Company. The architect is Mr. W. W. Crawford, who has gone out from England under engagement to the company. The plant will consist of three boilers, a Green's patent fuel economiser, and four Belliss compound engines. These will be coupled to three Johnson & Phillips patent shunt-wound dynamos, each capable of giving an output of 70 amperes, 420 volts, at a speed of 350 revolutions per minute, and two dynamos of the same make, capable of an output of 70 amperes, 210 volts, at a speed of 420 revolutions per minute. There will, in addition, be the usual batteries and switchboards. It is estimated that the whole of the works in going order will cost £9,000. The contract provides for 23 arc lamps of 2,000-C.P. each, and 66 incandescent lamps of 50-C.P. each. The arc lamps will be turned off at midnight, and incandescents kept alight till sunrise. The contract is for 10 years; but at the expiration of five years the Corporation may acquire the lighting plant at a valuation.

Portsmouth.—A contemporary says that the Town Council will shortly consider a report for the lighting of the ordinary street lamps with electricity at precisely the same cost as is now incurred with gas.

Sheffield.—The Town Council held a special meeting the other day, and passed a resolution approving of the Council promoting a local and personal Bill in the present Session of Parliament to confirm the agreement for the purchase of the undertaking of the Sheffield Electric Light and Power Company, and to confer borrowing and other powers on the Corporation.

Shoreditch.—The report made by Messrs. Kincaid, Waller & Manville to the Electric Lighting Committee of the Shoreditch Vestry was discussed at considerable length at the Vestry meeting held on Tuesday evening. The consulting engineers recommended the Vestry to instruct them to prepare detailed plans and specifications for the alteration of the destructor house and the erection of new coal and accumulator house, and for the boilers and requisite steam and feed pipe connections and necessary accessories; and also to furnish a further report on the terms as to which the makers would be prepared to increase the size of the battery. The cost of the work was estimated by the consulting engineers at £13,200, which included a provision of 10 per cent. for contingencies and extras. Having been advised on the matter by the chief engineer (Mr. Russell), the Lighting Committee recommended the Vestry to generally adopt the scheme proposed, and that it should be referred to the Committee to advertise for tenders for the work. An amendment was moved and seconded that pending the making up of the accounts, the report should be referred back to the Committee. Replying to criticisms made upon the report and electric light station, Mr. Kershaw, chairman of the Lighting Committee, stated that during the third quarter the whole scheme of electric lighting had resulted in a profit of £1,700. With regard to the thermal storage plant, that had not yet had a practical test, but if the terms of the specification were not fulfilled the contractors would not be paid. They were, however, now treating at the rate of from 30,000 to 40,000 tons of refuse per annum, and it was believed they would have the lowest works' costs in London, and perhaps less than those of the Leeds works, where coal only cost from 6s. to 7s. per ton. It was proposed to put down five dry back boilers to supply steam to the engines ordered some time ago, and this would enable the present output of 407 kilowatts out of a possible 456 kilowatts to be considerably increased. Only six members voted for the amendment, which was lost, and the original motion was carried. The Vestry authorised the Lighting Committee to order from the Electric Construction Company a 30-kilowatt transformer and four switchboard panels for the arc light system. The Lighting Committee reported having received an inquiry from the Electric Vehicles Syndicate, asking for a supply of current at 1½d. per unit during the day. The Vestry resolved to inform the Syndicate that the offer made was not acceptable, but that they would be prepared to consider a proposal on lines similar to the terms made with the London Electric Cab Company. Fifteen tenders were received for the supply of arc lamps in connection with the extension scheme. These were referred to the Lighting Committee.

Southampton.—At the last meeting of the Town Council the Electric Lighting Committee submitted a report, showing that the number of units metered at the works during March was 19,186, being an increase of 42·5 per cent. over the number for March, 1897. Having considered an application from a corporate committee with respect to lighting the public parks, the Committee had resolved to defer the consideration of the matter until the question of public lighting was somewhat further advanced. The electrical engineer reported to the committee that he had been in communication with several firms upon the matter of electric lanterns for the police, but, having regard to the cost, weight, and other circumstances connected with the samples submitted for his inspection, he could not recommend them to the committee. The committee's report was adopted.

Southport.—At a recent Council meeting, the Gas Committee opposed a proposal made by the Electricity Committee to add 42 arc lamps to the street lighting, and the motion was eventually withdrawn.

Southsea.—A Committee is to consider the desirability of lighting St. Jude's Church, Southsea, with electricity.

Stockport.—The Local Government Board has granted the application of the Council for a loan (£24,600) for electric lighting purposes, and has approved of the land lately occupied by the Millgate gas works as a suitable site for electricity works.

St. Pancras.—At last week's Vestry meeting, Mr. Thornley submitted a special return, showing that a beginning had been made at the destructor in generating electricity from dust. The committee hoped to bring up a more complete return on a future day. They had already generated some hundreds of units.

Sunderland.—The Town Council has adopted a report recently submitted by Mr. Snell, the borough electrical engineer, on the subject of electric lighting extensions. Application will in consequence be made to the Local Government Board to sanction a further loan of £26,000 to carry out the scheme, and subject to such sanction leave has been granted to borrow £10,000 for immediate requirements. Mr. Snell is drawing up specifications, and inviting tenders for two Lancashire or Galloway boilers, and all piping and accessories, one new Weir's pump, one new steam dynamo, complete with piping, &c., and two motor transformers. Mr. Snell has been also authorised to take steps so that the change to the 440-volt system may be effected in the spring of 1899, subject to the approval of the Board of Trade. In the report referred to the figures were given showing the increased demand which had rendered extensions necessary:—

Year ending.	No. of consumers.	8-C.P. lamps fixed.	Increase.	Max. load E.H.P.	Increase.	Capacity of station, E.H.P.	Capacity E.H.P. deducting stand-by.
Dec. 31st, 1896	118	11,289	—	294	—	345	210
Dec. 31st, 1897	170	19,177	7,888	499	205	480	345
Dec. 31st, 1898 (E)	—	23,750	4,573	680	181	715	480

To the present date the number of lamps connected has increased to 20,411, as against 19,177 in December last, or an increase of 1,234 in two months, to which must be added some 800 more applied for. The number of consumers has also increased from 170 to 191. The following table was also given:—

Year.	Electric H.P. required.	Total units estimated to be sold.	Estimated total capital outlay to end of year.	Working and sleeping costs.	Sinking fund and interest.	Total costs.	Revenue.	Net profit for year.
1898-9	680	418,550	£46,300	£3,580	£2,370	£5,950	£6,055	£105
1899 1900	800	529,470	£56,000	£3,860	£3,180	£7,040	£7,800	£760
1900-1	1,000	660,960	£69,000	£4,360	£3,700	£8,060	£9,430	£1,370

The estimate for all requirements to the end of 1901 is £12,728, but for immediate requirements the outlay will be £7,800. The report under the heading of "mains" says:—"The alternating plant is gradually being loaded up, and I expect will be loaded up by the year 1900. Instead then of adding to this plant, I propose to serve that district by direct current, and to lay a feeder (in the existing conduits which convey the high tension cable) to, say, the corner of Belvedere and Stockton Roads, looping up the now isolated pieces of distributing mains; a much more reliable, safer, and more economical system will thus be provided; a 24 hours' supply given with economy to all consumers, residents, and others alike, and the whole supply will be derived from one system instead of two. It must be distinctly understood that I do not propose to do this yet; but I shall require your sanction to this scheme to enable me to pave the way gradually for the change. I am confident, after the most careful and lengthy consideration of the matter, that this will be the best system for Sunderland, both immediately and when considering the future. The alternating plant could still be made use of for pioneering another district, *e.g.*, Roker, until such time as that outside system had grown to such extent as to warrant its transference to the general system. It may be necessary, when effecting this change (unless some arrangement is arrived at between the Corporation and consumers), to change the lamps in most of the consumers' premises, and to effect some minor alterations therein. The cost will not be large, compared with the very great advantages otherwise obtained. I wish to point out that the present mains will carry from three to four times the amount of energy without increase of section by this method, and therefore a very great saving will thus be effected. Estimate:—Extensions of feeders in present district, *required at once*, £675; mains to the workhouse, £2,200; new feeder to residential district, £1,665; three years' ordinary extensions of mains and services, meters, &c., £7,000; allowance for new lamps and alterations to consumers' wiring in certain cases, £1,000; total, £12,540."

Taunton.—The Taunton District Council long ago made itself conspicuous for its debates on electric lighting, and that reputation it has maintained up to the present time. No fair-minded man would wish to prevent legitimate discussion on the electric lighting question in any council chamber, but in some parts of the country there is a tendency among councillors to take every opportunity of finding fault with either the electricity works or the administrators thereof. There has been considerable heckling at Taunton from time to time, and one member in particular has been very much in evidence in the debates. Where the desire to oppose exists it is not unusual that actual facts should be ignored and gross mis-statements made. And it may often happen that these mis-statements will do a considerable amount of harm unless they are publicly contradicted. At Taunton it seems that the mis-statements have been so gross and so often repeated that the Electric Lighting Committee has felt itself compelled to give a quietus to two councillors who have circulated them. That body has, therefore, drawn up and issued to the local public a lengthy explanation, showing on the one side the mis-statements of Messrs. Standfast and Clement Smith, and showing, on the other side, item for item, the actual facts. The document is duly signed by the 10 members of the Electric Lighting Committee. A comparision of the facts and the mis-statements, allowing the necessary grain of salt on either side, is evidence of the extent to which public men can go in trying to prove their case. The matter is not of more than passing interest, though we suppose the issuing of this statement may lead to further protracted discussion both in the local press and in the council chamber, but borough electrical engineers and sometimes electric lighting committees in different parts of the land have to listen to most absurd statements from ignorant councillors, and though in most cases the statements are only worthy of contempt, there is yet such a thing as going too far. Then is the time to meet the matter in the way adopted by the Taunton Committee. It ought to have a healthy effect upon the Council generally.

Councillor Standfast has issued a circular in reply, in which he proves to his own satisfaction the inaccuracy of the Committee's statements.

Wallasey.—A Local Government Board inquiry was held on 14th inst. into the Council's application for a loan of £20,785 for electric lighting extensions. The sum is made up of £17,725 for electric lighting extensions proper, and £3,060 for purposes of street and promenade arc lighting. The amount of £17,725 is required to extend the engine and generating power, and to supply 150 more consumers. The sum of £3,060 is composed of £1,380 intended to be spent on 46 arc lamps and standards for the streets, and £1,680 for 16 arc lamps for the promenade, together with the necessary cables and attachments. The electric light was installed in the district and first used in the month of January, 1897. There were then 2,000 8-C.P. lamps in connection with the supply, but at present the number is between 5,000 and 6,000. The number of consumers is about 100. The profit for the 11 months ending March last was £840. Applications for energy were being received so fast that the committee were unable to comply with them owing to insufficient generating power. Since the system was installed the price had been reduced from 7d. to 6d. per Board of Trade unit, and a reduction had also been made for prolonged consumption. Evidence in support of the application was given by Mr. J. H. Crowther, lighting engineer.

West Ham.—The West Ham Board of Guardians has been considering the question of improved lighting of the Workhouse, and it was thought advisable to consult an engineer *re* laying down electric lighting plant. The Leyton District Council offered to supply current at 3d. per unit. The matter stands adjourned for a fortnight.

In the Corporation Bill power is sought to amend the provisions of the West Ham Electric Lighting Order, 1892, with reference to power to supply and let electric fittings.

Weston-super-Mare.—The Municipal Electric Supply Company, having offered to take over the Council's electric lighting order, the Council has written stating that, if it determines at any future time to dispose of its order, the company's terms shall be considered.

Winchester.—The Winchester Electric Light and Power Company has written to the City Council on the subject of street lighting. The present lighting contract terminates in a few months, and as a special arrangement was made for supply of current for all municipal purposes at 4d. per unit, the company has raised the question. The works are now about ready to supply current. We understand that tenders are being invited for lighting the streets for three or five years.

Wycombe.—The foundation stone of the electricity works was laid by the chairman of the Electric Lighting Committee last Saturday.

Yarmouth.—The new plant referred to last week comprises a 150-kw. steam alternator. Mr. Ranken, in his report recently, stated that the number of lamps connected has during the last two years been increasing at the rate of about 2,500 lamps per annum. Taking this figure as likely to continue during the next 18 months, he estimated that the number of lamps connected will, in September, 1899, be about 14,700, increased to 15,300 if the Council carried out the illumination of the Drive by festoons of coloured glow lamps. Towards the end of the season 65 per cent. of the lamps are in use at one time, so that before the 1899 season it will be necessary to provide enough machinery to supply 10,000 lamps alight simultaneously, with sufficient reserve plant. The new plant will enable the works to supply 12,000 lamps at one time, leaving one 150-kilowatt set in reserve. No addition to the boilers will be required until it was necessary to increase the engine room plant, which, at the present rate of growth, would not be till 1901. It would be advisable to order this plant not later than June next, as most of the manufacturers have so much work in hand, that they will require a year to execute the contract. The Council resolved to apply to the Local Government Board for sanction to a further loan of £4,800, and that Mr. Preece be consulting engineer for the new engine and alternator. The items in the application would be as follows:—Steam engine, 1,500 kw., alternator and steam pipes, £2,800; additional high and low tension mains, £1,600; transformers and transformer stations, £400; total, £4,800. The quarterly electric light statement showed that the receipts totalled £1,203 5s., leaving a margin of £564 2s. 9d. over the cost of production, which is sufficient to pay all capital charges, interest, and sundries. The accounts for the nine months ending December 31st showed that the income had met expenditure, including repayment of capital, within £327. Out of capital repayments during the year of £852, the surplus revenue from the light had paid £525.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Ayr.—There was a brief discussion at last week's Council meeting regarding electric traction, a proposal to put down overhead trolley lines having been submitted by Mr. Bickerdyke, of Montreal.

Bradford.—The deputation which went to the Continent early in March to inspect electric traction systems with reference to the supply of electricity for electric lighting and electric traction purposes from the same plant, has issued its report. The deputation consisted of the Mayor, Councillors Dixon and Shaw, and Mr. Gibbings (borough electrical engineer), and paid visits to Brussels, Hamburg, Berlin, Dresden and Leipzig. After taking into consideration all that the deputation saw they express themselves satisfied that the arrangements already made at the Valley Road electricity works for running the Bolton Road and Great Horton tramways, are as complete as anything seen on the Continent, but the Continental generating stations are very much larger and finer than anything in this country. Instead of making undue haste in the matter of electric traction or lighting the committee says that we are considerably behind the development which has already taken place in each of the towns visited. It appears to be the practice to utilise either the accumulator system or the conduit system for crossing the more important thoroughfares in the centre of the town with electric trams, "thus doing away not only with the unsightliness but possible danger of the overhead wires," and although the initial cost of the conduit system is considerably higher than that of the overhead, it was found to be far preferable in the centre of the cities visited.

Bristol.—Pursuant to the instruction of the Bristol City Council, the Tramway Committee of that body have taken steps to continue, or rather to re-open, negotiations with the Bristol Tramway Company with regard to the extension of their system and the adoption of electric traction. One of the points upon which a deadlock had occurred was as to the period at which the new lines should be purchasable by the city. The committee desired they should be purchasable at the same time as the old horse lines, in other words, about 14 years hence. The company stuck out for the full 21 years allowed by the Tramway Act. An intimation had been since given that the company were prepared to throw their various lines together and to give the city power to purchase the whole in 18 years. The Bristol city engineer has calculated what the period would be on simple mathematical lines and finds it works out to 16 years and 7 months. Thereupon the committee suggested the term should be 16 years 6 months, so that 18 months only separated them from the company upon this point of the negotiations. The company's representatives asked for an interview with a deputation from the committee, and on Monday the Sanitary Committee commissioned their chairman (Alderman Cope Proctor) and vice-chairman (Mr. George Pearson, who happens to be chairman of the civic electrical department) to meet the company's nominees and talk over the whole subject. The citizens, the great majority of whom are anxious electric traction should not be delayed, are now hopeful that terms will still be arrived at.

The Kingswood Council has been informed by the Light Railway Commissioners that they propose issuing the order applied for by the Bristol Tramways Company to authorise the construction of a new line from St. George to Hanham. The Council was asked to make any suggestions thought necessary.

Cable Traction.—It is interesting to note that Messrs. Dick, Kerr & Co., have just secured a contract for the equipment of cable tramways at Edinburgh for the sum of £89,000.

Christchurch and Poole.—The Pokesdown District Council has resolved to grant the representatives of the British Electric Traction Company an interview in order to discuss their new scheme of a light railway from Christchurch to Poole.

City and South London.—An evening paper says that the contract for the construction of the extension of the City and South London Railway from Stockwell to Clapham Common has been placed. This extension is to be completed in 15 months.

Cork.—The electric tramway and lighting plant and undertaking, which was commenced last November, is said to be approaching completion. It is expected that the lighting will be in operation by the end of May, and the tramways before July 1st. Orders are being booked for lighting current. There is a local free wiring company. The chief engineer of the undertaking is Mr. Horace F. Parshall, and Mr. Wright, of Brighton, is stated to be in charge of the lighting arrangements at Cork. Mr. Richard D. Walsh, C.E., of Dublin, is the engineer for the tramway construction, and Mr. Merz and Mr. Beverley Griffin are the resident engineers for the electric works and tramway construction respectively.

Coventry.—The work of extending the electric tramway system is being rapidly carried out in Coventry. The extension is nearly six miles in length, and will open up communication with the outlying districts. The existing line, which has been successfully working for several years, connects Coventry with Bedworth, a distance of about seven miles.

Dublin.—Before the Judicial Committee of the Privy Council, sitting at Dublin Castle last Saturday, application was made by the Dublin United Tramways Company for an order in Council to authorise the construction and extension of several tramways in the County of Dublin, in the Townships of Rathmines and Rathgar, Pembroke, Drumcondra, Clonliffe, and Glasnevin, and Clontarf, in the City of Dublin. The matter was adjourned for four or five weeks. The Dublin Corporation had the previous day passed a resolution approving of the scheme conditionally.

Liverpool.—The Corporation Tramways Committee on Friday last inspected specimens of an American-made, and of a German-made, electric car for the new experimental electric line to the Dingle, and they have decided to order a number of cars of each make.

Leeds.—The Tramways Committee is to purchase 10 additional trailer cars.

New Conduit System.—A model car and tramway on the Munson electric conduit system has been fitted up at the Glasgow Corporation Tramways works, in St. James Street, by the Munson Electric Conduit Company, of Chicago. There was a press inspection on 15th inst. Mr. Wm. Arnot, late electrical engineer to the Corporation, explained the working of the system. The system is described in the Glasgow papers as follows:—"Within the conduit, placed at intervals regulated by the length of the car, are small gun-metal rollers. These rollers are fixed on the end of a plunger, to the other end of which there is attached a tongue, which is in metallic connection with the roller. Opposite the tongue are two contacts connected with the main wire, which is equivalent to the trolley wire on an overhead system. This main wire is laid in solid insulating material, such as hard bitumen. Opposite the roller is a second one connected similarly, and having the main return wire on the other side. The action that takes place while a car is running is that, when the plough which protrudes underneath the car comes between the two rollers it forces them inwards, the tongue on the end of the plunger in both cases going in between the two contacts which are connected with the main cables, and completing the circuit, the motor is actuated in the usual way. Whenever the car leaves these two rollers they are forced out, and then become quite dead—that is to say, no electricity is in them. The plough of the car, before leaving one pair of rollers, makes contact with the pair in front. The great point claimed for the system is, that the entire system is an insulated one on both sides, that the return current is not taken back by the rails, hence there can be no trouble with the electrolysis, and that no bonding of the rails is required."

Paisley.—At a meeting of the Town Council on the 12th inst., it was stated in the minutes of Council that at a recent committee meeting Mr. Emile Garcke, manager of the British Electric Traction Company, Limited, was introduced and heard with reference to the proposed construction of electric tramways in the burgh and as to the probable requirements of the company for supply of motive power from the Corporation works. After a lengthened statement, he asked that the Council should agree to the principle on which the proposals of the company are based, subject to the terms of the provisional order to be obtained by the company, and the system they propose to adopt, being satisfactory. Mr. Garcke having retired, the clerk read letters from the Simplex Electric Tramway Conduit Syndicate, Limited, and from Mr. R. Bickerdyke, vice-president of the Banque d'Hochelaga, Montreal, calling attention to the merits respectively of the "Simplex" and "American Electric Trolley" systems of electric traction. These he was directed to hand to Mr. Teague, and it was agreed to defer consideration of these and of Mr. Garcke's proposals until Mr. Teague has reported in terms of instructions.

The Electric Power Schemes.—The Clerk to the Derbyshire County Council has informed the Blackwell District Council that the General Electrical Power Distributing Company has decided to put certain clauses into its Bill that would meet a good deal of the opposition now directed against it by various public authorities. The introduction of these clauses would practically wipe out the Blackwell opposition.

As there has been so much opposition raised to the scheme of the General Power Distributing Company, the *Derbyshire Times* discusses the advantages of the scheme at some length.

Roumania.—The Helios Company of Ehrenfeld, Cologne, is reported to have secured a contract for the construction of an electric tramway in the town of Braila, Roumania.

Sheffield.—The question of site for the electric tramway power station is occupying attention at the present moment. Various sites have been suggested, and various opinions are held as to their suitability. The Tramways Committee recommended, and the Council approved, of the Kelham Island site, and Mr. H. F. Parshall, of the British Thomson-Houston Company, expressed the opinion that this was in all ways suited for the purpose. Dr. Hopkinson in his report discussed the respective advantages of half-a-dozen sites, and we abstract a few of his remarks:—"Kelham Island is in reality less advantageous in position than would appear at first sight, because it will not be convenient to lead out conductors in the most direct way for the supply of the district to the north-west and west. The conductors for this direction must be brought back to Alma Street, and part of them as far back probably as the Borough Bridge. The station further is actually at a greater distance from the centre of the district than any one of the remaining four. Water for condensation is, of course, readily obtained, but the whole of the coal required would have to be brought in by cart. . . . Johnson Street is favourably situated in regard to the work to be done. Comparing it with Kelham Island, it is a little more central; it is equally advantageous with regard to condensation, and it may be better placed for bringing in coal if the overhead gantry can be carried out. . . . Assuming that the foundations were all good, and not requiring piling, I should on the whole prefer Johnson Street. But the advantage of one over the other is not so great that it would be worth while going into any very large expenditure in purchasing one site rather than another. A perfectly successful result should be obtained with any one. It has further been suggested to me that the tramway generating plant might be placed on a part of the land occupied by the present electric lighting station. The station is well situated in relation to the work to be done, and I understand there is water for condensation. There is also sufficient room in the existing buildings for enough machinery for present requirements. I see no objection to the plant immediately required being placed there, and to leaving the question of where a larger plant shall be fixed to be settled later."

Sunderland.—The Council has decided to send a deputation consisting of the Mayor, Tramways chairman and vice-chairman, borough engineer, and the borough electrical engineer (Mr. J. F. C. Snell) to the Continent, to obtain information respecting electric traction.

West Derbyshire Light Railway.—At a meeting of the Derbyshire County Council last week it was reported that the promoters desired to increase the width of the gauge from 4 feet to 4 feet 8½ inches. The Council decided to raise no objections, on certain conditions, among them being:—That no steam power shall be used on the line; that the length of the trains shall be restricted to two carriages, in addition to the carriage carrying the motor power.

Whitley.—A poll was taken on Saturday of the parochial electors and ratepayers of the urban district of Whitley and Monkseaton, to ascertain the feeling with regard to the proposed introduction of electric tramways. The result of the ballot was: For the tramways, 260; against, 220; majority for, 40.

TELEGRAPH AND TELEPHONE NOTES.

Australian Overland Lines.—It appears, says the *Financial News*, that the South Australian Government has decided upon the desirability of duplicating the overland telegraph by the erection of a second wire to Port Darwin. The subject has claimed attention as a result of the recent interruptions in the existing wire, and the complaints they have entailed. The double wire, when the intended addition is completed, will have a working capacity nearly four times greater than the existing single one, and this will greatly facilitate the transmission of messages and prevent a block on the line. The cable company has two cables to Port Darwin, and, as South Australia has only one wire, the cable has at present an advantage over the land line. There are over 2,000 miles to be traversed, and it is expected that the work will be completed about the end of the year. The total cost is estimated at something over £50,000. The Agent-General in London has been advised of the materials required for the work, and is now only awaiting the receipt of a cablegram to put the order in hand.

The Cuban Crisis.—It is stated that the Minister of the Colonies for Spain has approved of a contract for the laying of a telegraph cable between Cadiz and Havana *viâ* Teneriffe and Vieques, an island near Puerto Rico.

Delays in Australian Telegrams.—We reprint an extract from the *Sydney Morning Herald* of the 12th ult., which shows that the Australian public is perfectly alive to the inconvenience caused by the very frequent interruptions to the Australian landlines. We believe that the South Australian Government propose to remedy this very unsatisfactory state of affairs by putting another wire on the same poles as the present line from Adelaide to Port Darwin is carried upon. It is estimated that this proceeding will cost something over £50,000, but it seems absurd to expect that by putting additional weight on these poles they will stand any better than they do at present. It has been stated in the House of Commons that the Colonies are making no movement in favour of a cable across the Pacific, but it is difficult to understand how the public can do more than protest in the press, and how the Premiers of the Colonies can express themselves more strongly than they have done at the recent Federation Conference, where it was agreed, with regard to the Pacific cable, "That if Great Britain and Canada would contribute each one-third of the cost, the four eastern Colonies, Queensland, New South Wales, Victoria, and Tasmania, would favourably consider the proposal to provide the remaining one-third of the contribution." As regards the official notification of the delays in Australian telegrams, a correspondent in the *Sydney Daily Telegraph* writes concerning the telegraphic department of South Australia, which, he says, "sends to the Sydney office the most misleading information regarding the state of cable business. To go no further back than yesterday, the official notice read as follows:—'London, 8.28 p.m., March 2nd. Received Adelaide 7.7 a.m., March 3rd, equal to 8 7 a.m. Sydney.' Whilst the actual experience of business people was:—'London, 6.50 p.m., March 2nd. Received Sydney Telegraph Office 5.40 p.m., 3rd idem (after business hours)' or a difference of no less than 11 hours 11 minutes between official representation and actual facts, whilst for business purposes the difference was equal to 24 hours."

The extract above referred to from *Sydney Morning Herald* runs as follows (we would merely premise that "Broome" is identical with Roebuck Bay):—

"CABLE COMMUNICATION.

"*A Series of Interruptions. The Record since January.*

"The imperfections of the present means of communication between Australia and Europe have been the cause of increasing dissatisfaction among commercial classes. Local feeling on the subject was expressed on Thursday by the deputation (from the Sydney Chamber of Commerce) that waited on the Postmaster-General; and although it cannot be said that that deputation exhausted the possibilities of the subject, it brought the question into prominence, and gave the movement towards reform an impetus that it much needed. The main object of the deputation was to advocate the claims of the Pacific cable. A more general question, and one in which all sections of the public are directly interested, is that which is concerned with the reasons for the interruptions, their increasing frequency, and the possibility of an improvement in the present state of affairs. That there has been more trouble with the cable service of late than was the case formerly Mr. Cook admitted. As a well-known merchant said to a *Herald* representative yesterday, messages are delayed, and it is impossible for the person who receives them to be certain how long the delay has continued. He is unable to say whether the message was put in half an hour, an hour, or 10 hours ago. To the commercial world a doubt of this kind is often attended with serious consequences. The uncertainty is, in fact, the worst feature of the case.

"Speaking generally, it may be said that the interruptions which have occurred during the past few months have occurred on the overland service. There are practically two overland lines connecting Sydney with Europe. The bulk of the work falls upon the line between Port Darwin and Adelaide. This is the principal medium for transmission of English and Continental intelligence. There is another line which crosses the south of the continent and connects Broome in the west with Port Adelaide in the south. This line serves as a sort of second string for the line running north and south, but it is in an almost chronic state of disrepair. As far as the lines between Adelaide, Melbourne, and Sydney are concerned, there is seldom any difficulty. Occasionally, as happened two or three weeks ago, heavy rains and swollen rivers may delay communication for a day or two. But the question practically narrows itself down to the condition of the line between Adelaide and Port Darwin and that between Adelaide and Broome. It is these two which transmit foreign intelligence to the more central colonies, and it is with their efficiency, or otherwise, that the public are chiefly concerned.

"Probably only those immediately interested are aware how numerous of late have been the interruptions to the overland telegraph service. Occasionally something is heard of a deep-sea cable going wrong, but, taking the period from the present time back to the beginning of the year, it may be said that the difficulty has been entirely with the overland route. In the press, the heading 'Telegraph Interruption' has appeared with monotonous frequency. On Thursday last it was announced that the 'Port Darwin line is unworkable, and cables are being transmitted *viâ* Broome.' On the Tuesday previous, March 8th, the announcement appeared that the Port Darwin line was interrupted between Katherine and Port Darwin. On March 7th the familiar heading was again in evidence, and this time it was the Broome line that was out of order. On March 2nd there was an interruption on the Port Darwin line. On February 26th the *Herald* explained that there was no English news of the previous day, as the Port Darwin circuit was affected. An announcement of February 11th stated that the Port Darwin line was interrupted north of Woodnadatta. On February 9th came the news of another interruption to the same line; and going back to February 2nd there is still another, this time the news being accompanied by the additional intelligence that the line between Perth and Roebuck was working badly. On January 31st over 200 poles were down on the line between Overland Corner and Renmark. On January 24th an expedition had to be sent from Port Darwin to enable communication to be restored. On January 13th European messages were delayed through an interruption to some part of the overland line. In all 13 interruptions—some of them trifling, some were serious—have occurred on the overland line during the beginning of the year. The numbers are taken from announcements made in the columns of the *Sydney Morning Herald*. No official record has been kept locally, and it is possible that no mention has been made of interruptions of the more trifling kind. But enough has been said, however, to show that the representations of Thursday's deputation were well founded.

"As has already been announced, the South Australian Government has undertaken the continuation of a duplicate line between Port Darwin and Adelaide. The line will, however, for the most part be worked upon the same telegraph poles as those which support the present one, and for this reason the scheme is not received with much favour by commercial men in Sydney. Mr. H. C. Mitchell, secretary to the Chamber of Commerce, said yesterday that he was confident that nothing but the construction of the Pacific cable would satisfy local requirements. The convenience would be very great, and the saving would, he thought, be enormous. The Eastern Extension Company, while offering to lay a line from Natal to Port Darwin, made no offer to reduce the cable rates. The proposed Pacific cable would convey messages at a rate cheaper by 1s. 9d. a word than that at present in force. 'In five years' time,' said Mr. Mitchell, 'there will be four million words passing annually between here and Europe. A saving of 1s. 9d. a word means a saving on that of £360,000 a year. If the work is to be done, it should be done by the Government. The overland line may be interrupted, and the proposal of the Eastern Extension Company does not seem satisfactory. The Pacific cable would pass through British territory, and would be the cheapest in the end."

Interruption to Cape Cables.—During the present month two of the cables which form part of the main line from England to the Cape along the West Coast of Africa have been interrupted. The cable which connects Sierra Leone with Accra was interrupted on the 9th and was restored last Tuesday (19th). Another cable, which runs from Mossamedes to Cape Town was interrupted on the 14th and is not yet repaired. Thus, since the 9th of this month we have been depending for communication with the Cape on the cables along the East Coast from Aden; of which only the Mozambique-Zanzibar section is duplicated. The frequency of the interruptions to the Cape cables emphasises the necessity for laying the proposed alternative line *viâ* St. Helena and Ascension. In addition to the above we learn that another cable on the West Coast, *i.e.*, that from Mossamedes to Benguela, broke down on Wednesday.

The Privacy of Telegrams.—In reference to the order recently issued to the staffs at the various Post Offices on this very important subject, a correspondent of the *Standard* asks, What is the use of this order, when the contents of telegrams are telephoned from sub-offices to the Central Telegraph Offices in such a way that anybody in the sub-office can hear the whole contents of the telegram, together with the names of the addressee and sender? The other day he had occasion to send a telegram, and some question arising respecting it, he was catechised across the public office (then full of people) by the clerk in communication with the telegraph room. What made the circumstance the more annoying was that the message was perfectly in order. But at the busiest hour of the day the receipt of telegrams at a "first-class" provincial office was left to the care of one girl.

The Telegraph Wire Export Trade.—Quite an active trade was done in the exports of telegraph wire and apparatus connected therewith during the past month, the total value of the shipments amounting to £135,583, as compared with only £75,276 in February last, and against £139,642 in March, 1897. The total value of the exports for the first three months of the year may be considered satisfactory as it amounts to £246,788 as compared with £245,472 in the same period of last year, and only £188,302 in the first quarter of 1896.

The Telephone Service.—The St. Pancras Vestry, as the road authority for the parish, has refused to give sanction to the National Telephone Company to place their mains, pipes or wires underneath the streets of St. Pancras until the interests of the public in regard to the telephone service are duly secured by statute.

CONTRACTS OPEN AND CLOSED.

OPEN.

Aberdeen—The Council invites tenders for the supply and laying of about 10 miles of ·67 single core feeder cable, 5 miles of ·2 three-core network cable, and 3⅝ miles of arc lamp series cable. The cable is to be armoured and laid in wooden casing. Under another contract the Harbour Commissioners invite tenders for the supply and erection of 62 arc lamps and three leading lights, each consisting of four arc lamps. All lamps to be Brockie-Pell or Crompton-Pochin. Both the contracts will have to be completed by August 31st, and particulars in both cases can be obtained from the Corporation Electricity Works, Cotton Street. See our "Official Notices" this week.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Bootle.—April 25th. The Corporation wants tenders for the supply and erection of arc and incandescent lamps, lamp posts and accessories. Engineer, Mr. T. L. Miller, Liverpool. See our "Official Notices" April 15th.

Dudley and Stourbridge.—The Dudley, Stourbridge, and District (Staffs.) Electric Traction Company is inviting tenders for the erection and completion of a power station (with chimney stack), car shed, walling, &c., on a site near Dudley Road, Hart's Hill, Brierley Hill. Drawings, specification, &c., from Mr. Thomas Robinson, architect and surveyor, Victoria Chambers, Stourbridge, on deposit of £1 1s.

Edinburgh.—April 23rd. The Midlothian and Peebles Lunacy Board is inviting tenders for the installation of electric light in the Asylum at Rosslynlee, near Edinburgh, including (1) generating plant, accumulators, switchboard, &c.; (2) wiring, fittings, &c. Particulars may be obtained on application to Prof. Bailey, Heriot-Watt College, Chambers Street, Edinburgh.

Hyde.—May 5th. A Corporation Committee invites tenders for the supply and fixing of gas engine, dynamo, wires, fittings, &c., for electric lighting at the new technical school and free library. Engineers, Messrs. Lacey, Clirehugh & Sillar, 78, King Street, Manchester. See our "Official Notices" this week for particulars.

London.—May 17th. The Bethnal Green Board of Guardians invites tenders for the supply of plant, and installing the electric light at the new infirmary, Palestine Place. Plans, &c., to be obtained from the architects, Giles, Gough & Trollope, 28, Craven Street, Charing Cross, W.C. See our "Official Notices" this week for particulars.

Roumania.—April 30th. Tenders are being invited until the 30th inst. by the Roumanian Post and Telegraph Authorities in Bucharest, for the supply of 50 tons of galvanised iron wire, 10 tons of galvanised steel wire, and 5 tons of tinned copper wire. Particulars may be obtained from, and tenders to be sent to, La Direction Générale des Postes et Telegraphes, Bucharest, Roumania.

Sunderland.—April 29th. The Corporation is inviting tenders for the supply of a high-speed 225-kw. steam dynamo, and two Lancashire or Galloway boilers. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" April 15th for particulars.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

Waterloo (Lancs.).—April 26th. Tenders are invited for wiring and fitting the Town Hall for electric lighting. Particulars from Mr. F. S. Yates, surveyor to the District Council.

CLOSED.

Bootle.—The Town Council has accepted the tender of the Chloride Electrical Storage Syndicate for supplying and fixing two storage batteries at the electricity supply works for the sum of £1,079, and for the maintenance of same at £64 per annum.

Dudley and Stourbridge.—An inclusive contract for the electrical equipment of the Dudley and Stourbridge tramways has been placed with the British Thomson-Houston Company, Limited, and work will be commenced immediately.

Portsmouth.—A contract has been given to Messrs. Yates & Thom for the supply of boilers, feed pumps, mechanical stokers, coal conveyor, &c., at a cost of £7,900.

Walsall.—The Council has accepted the tender of Callender's Cable and Construction Company, Limited, for supplying and laying new feeders and relaying old ones for £1,815 odd.

FORTHCOMING EVENTS.

1898.

Friday, April 22nd, 5 p.m.—Physical Society. "On a Method of viewing Newton's Rings," by the Rev. T. C. Porter.

Monday, April 25th, at 8 p.m.—Society of Arts. Second Cantor lecture on "Sources of Commercial India-rubber," by Dr. D. Morris, C.M.G.

Tuesday, April 26th, at 8 p.m.—The Institution of Civil Engineers. Annual general meeting to receive report and to elect council and auditors.

Wednesday, April 27th, at 7.30 p.m.—Institution of Electrical Engineers. Students' meeting. Paper on "The Commercial Development of the Electric Lighting of Small Towns," by C. Milton and H. Bell.

NOTES.

Prevention of Vibration.—*Apropos* of the recently much-advocated felt mat for deadening noise on solidly laid tramways, *Cassier's Magazine* names a case where a noisy engine was completely checked of jar and tremble by bedding it in a shallow pan of hair felt placed between the stone bed and the engine frame, the pan sides preventing the lateral extension of the felt. Noise due to rigid connections may be deadened considerably in this way, vibration or sound waves being probably unable to propagate themselves between diverse materials. Resonance is the best term to employ in respect of many cases where noisy machinery is found. The same applies to the resonance of a rigid rail or tramway which it is hoped to check by the felt mat, which is made from one-third of an inch in thickness and upwards. Such deadness of sound ought, however, not to be thick, or they will yield under passing pressure, and place vehicles in the position of always running uphill, which it is the object of the rigid girder rail to prevent. Mr. Deacon, of Liverpool, professes that an elastic supported rail is productive of great saving, but he does not advance figures to show the difference in traction where a rail is rigidly supported, or has a yielding elastic support.

Some New Galvanic Cells.—Carbon electrodes immersed respectively in concentrated chlorine water and sodium thiosulphate solution, form essential features of a new cell described by H. Pauling in the *Zeitschrift fur Elektrochemie*, No. 5, page 332. The liquids are separated by a porous pot soaked in brine. During action the sulphur separates out from the thiosulphate solution. Pauling has tested this cell, and found that the electromotive force fell on short circuit, from 0·64 volt to 0·47 volt, and then remained constant for five hours, the current passing being 0·7 ampere. In another cell, which is also described by H. Pauling, the electrolyte is a concentrated solution of ferric chloride, and the electrodes are of iron and carbon respectively. The author considers that the following reactions take place in this cell:—

$$\left\{\begin{array}{l}(1)\ 3\,Fe\,Cl_3 = 3\,Fe\,Cl_2 + 3\,Cl.\\(2)\ Fe + Cl = Fe\,Cl_2.\end{array}\right.$$

The chlorine gas reconverts the ferrous chloride into ferric chloride. The principal advantages of this cell are its cheapness and freedom from odour, whilst the electromotive force is only 0·9 volt. Depolarisation is, of course, the chief difficulty, but by means of a simple mode of construction a constant flow of ferric chloride solution is maintained throughout the cell, and this is claimed to be sufficient to ensure complete depolarisation. In the same number of the *Zeitschrift*, page 383, there is a paper by F. W. Kuster on the last-mentioned cell. Kuster considers that the process which takes place in the cell is better represented by the equation

$$2\,Fe''' + Fe = 3\,Fe'',$$

the dashes indicating the number of positive charges of electricity. Since the iron is always contaminated with finely-divided carbon or iron carbide, local galvanic action must occur of the same kind as the main reaction taking place in the cell. That this is the case was proved by an experiment in which the iron plate lost 1·66 grammes in weight, whereas the loss corresponding to the quantity of electricity produced should have been 0·31 gramme. That the iron dissolves as ferrous chloride and not as ferric salt was shown by immersing the iron plate in a solution of sodium chloride and the carbon plate in a solution of ferric chloride. After allowing the current to pass for some time, the solution in the vicinity of the iron plate was found to contain ferrous salt alone without a trace of ferric iron.

Lectures, &c.—A demonstration of the application of electricity to cooking and heating purposes was given on Monday last week before the Edinburgh South Side Merchants' Association by Mr. Hugh Fleming.

On 11th inst., before the Royal Scottish Society of Arts at Edinburgh, Mr. William Shaw, Pleasance, read a paper, in which he gave a detailed description of an electric system of mechanical ventilation which he had invented.

Tramways and the Light Railways Act, 1896.—In reply to an application addressed to the Board of Trade, we have received the following important communication:—"With reference to your letter of 13th inst. on the subject of the above-named Act, I am directed by the Board of Trade to state that they have been advised by their solicitor that there is no reason why an application under the Light Railways Act, 1896, for a light railway entirely within the limits of a borough should not be entertained, provided the order is properly framed."

Appointment Open.—The Government of Lagos, West Africa, want an engineer of Government vessels (£350 per annum). Applicants must be marine engineers with a knowledge of electric lighting plant. Preference will be given to marine engineers who are now in electricity works. See our "Official Notices" this week for conditions of engagement, &c.

The Electrical Work at Newington Baths.—Messrs. Sharp & Piper, in equipping the recently opened Newington Baths with electrical plant, have completed a most interesting installation. The plant consists of a Thwaites-Crichton double 6 inches and 10 inches × 6 inches compound engine developing at 80 lbs. pressure 35 B.H.P. at 470 revolutions. This is coupled to an Easton, Anderson and Goolden dynamo (Fynn's patent), of four-pole shunt-wound type. This machine has an output of 80 amperes at 225 volts, and is fitted with shunt regulating resistance. There are 125 11-plate R type Chloride Electrical Storage Company's cells having a total capacity of 276 ampere-hours, when discharging in six hours. The battery is used mostly for the light loads. The lighting is done by arc and incandescent lamps, there being 16 32-hours 10 amperes Brockie-Pell lamps placed as follows:—Four in series in first class swimming bath, four in series in second class swimming bath, two on pavement on ornamental standards in series with two in ladies' swimming bath, and two in manure yard in series with two on brackets on outside of building. Street standards, fitted with two 32-C.P. each, to turn on after 12 at night. The incandescent lighting is done by 320 incandescent Ediswan lamps, 16 and 8 C.P., having a terminal voltage of 220. The wires and mains through basement and wash-houses, &c., are enclosed in iron armoured insulated conduits, fitted with drawing-in boxes, &c., and we must say, from our observation, that the character of the work done at the Newington Baths is certainly an argument in favour of interior conduits. The wires and mains in the dwelling portions are enclosed in casing thoroughly varnished inside and out with shellac varnish. As we have already indicated, the fittings throughout are specially designed for 220-volt work. The electrical work in the stables is interesting, because it comprises both lighting and electrical driving. There are 32 16-C.P. 220-volt lamps, arranged on special fittings, and the whole of the provender machinery is driven by electric motors. The whole of this part of the contract, including the shafting, motor, chaff cutter, corn mills, friction hoist and elevators, was supplied and fixed by Sharp & Piper, and designed by Mr. J. B. Cumberland, chief of the engineering staff of the above firm. It comprises a 12½-13 H.P. Sharp and Piper motor, 50 amperes, 220 volts, 780 revolutions, shunt-wound, and fitted with patent starting resistance, driving a 2¼ diameter shafting, which runs at 200 revolutions. To this is geared the chaff cutter, fitted with fast and loose pulleys and bell-striking gear, capable of cutting and sifting 25 cwt. of chaff per hour, the power required being seven to eight B.H.P. Then there is the oat mill, fitted with fast and loose pulleys, capable of crushing 25 bushels oats per hour, the power required in this case being four B.H.P. In addition is a bean mill, fitted with fast and loose pulleys, and capable of splitting 25 bushels of beans, peas, or maize per hour, the power required being 1½ B.H.P. There is friction hoist for raising light loads, which can be made to raise, lower, or break by means of one pull on cord running off the shaft. It is perhaps hardly necessary to say that the character of the installation is very complete, and reflects much credit upon the contractors.

Internal Resistance of Galvanic Cells.—Last year, Ernst Haagn, in the *Zeitschrift für Physikalische Chemie*, No. 23, pages 97—122, described a method for the determination of the internal resistance of cells, which is fundamentally similar to the Wheatstone bridge method for the comparison of the capacities of condensers, the known ratio of the capacities giving the ratio of the resistances. The availability of the method for various classes of cells is first proved by comparison of the results obtained with those obtained by other methods. The experiments afterwards show that the internal resistance of cells during electrolysis is quite independent of the current strength or current density. The slight variations which were found to occur are traceable to alterations in the concentration of the solutions. In the case of accumulators during discharge, the resistance at first slowly increases, the rate of increase being more rapid towards the end, whilst during the charging of the cell the reverse changes occur, the resistance at first diminishing rapidly, and afterwards more slowly. The cause of this variation is partly the change in concentration of the sulphuric acid, and partly alteration of the surface of the lead plates. Haagn has continued his researches, and has more recently turned his attention to the determination of the resistance of galvanic cells with small polarisation capacity. If the resistances in the arms of a Wheatstone bridge are R_1, R_2, R_3, and R_4 (R_3 and R_4 referring to the halves of the bridge wire), and the arms 1 and 2 contain in addition capacities, C_1 and C_2, balance is obtained when $R_1 / R_2 = R_3 / R_4$, and $R_3 / R_4 = C_2 / C_1$ simultaneously. The present method is based on this. The cell, of which the resistance (R_1 say) is to be measured, has a capacity, C_1. The measurements are made by the telephone method, and in order to get a good minimum, the arm of the bridge containing the comparison resistance, R_2, must also contain a condenser of capacity, C_2, fulfilling the requirements of the above equation. A suitable condenser may be made by immersing two aluminium plates in sulphuric acid of maximum conductivity; a current is then passed between them with an E.M.F. of about 10 volts for a minute, when the aluminium plates become polarised, so that a smaller E.M.F. than 10 volts causes no current to pass in the same direction, and this condition is retained for a considerable period. The capacity of the condenser is varied by varying the depth to which the plates are immersed in the acid. In order to prevent direct current from the cell passing through the telephone circuit, an air condenser is included in it. The measurement is made by first adjusting the bridge contact to an approximate minimum of sound in the telephone; a nearer approximation is obtained by adjusting the depth of immersion of the aluminium plates, and then the final adjustment of the bridge contact is made. The method is applicable, whether current is flowing through the cell or not.

Manchester Electric Lighting.—The Manchester Electricity Committee's estimates for the year ending March 31st, 1899, set down the estimated expenditure on revenue account at £53,829; estimated income, £66,000; balance, £12,171; out of which it is expected that £12,000 will be devoted to the relief of the rates. The capital expenditure is put down at £143,900. Last year the surplus was £14,080.

Personal.—As we go to press we hear that Mr. George White, managing director of the Bristol Tramways and Carriage Company, was yesterday (Thursday) elected president of the Bristol Stock Exchange.

Earl Russell Studying for the Bar.—It is stated in the daily papers that Earl Russell has entered his name for the Bar.

NEW COMPANIES REGISTERED.

Mansfield Motor Car Company, Limited (56,901).—Registered April 9th, with capital £5,000 in £10 shares, to carry on the business of automotor and cycle manufacturers, pneumatic tyre manufacturers, electrical, gas, and mechanical engineers, cycle manufacturers, ship and boat builders, machinists, fitters, &c. The subscribers (with 10 shares each) are:—W. J. Chadburn, Grove House, Mansfield, brewer; G. A. Fish, Nottingham Road, Mansfield, ironfounder; F. Hameyer, Nottingham Road, Mansfield, ironmonger; C. Manners, Edenbank, Mansfield, printer; F. A. Robinson, The Park, Mansfield, ironfounder; R. F. Vallance, The Ridge, Mansfield, architect; J. J. Ward, The Park, Mansfield, manufacturer. The number of directors is not to be less than three nor more than seven; the first are W. J. Chadburn, G. A. Fish, F. Hameyer, F. A. Robinson, R. F. Vallance, and J. J. Ward; qualification, £100; remuneration as fixed by the company. Registered by Jordan & Sons, Limited, 120, Chancery Lane, W.C. Registered office, Leeming Street, Mansfield.

Mexico Electric Tramways, Limited (56,932).—Registered April 13th, with capital £500,000 in £1 shares, to adopt an agreement with Wernher, Beit & Co., and to construct or purchase, equip, maintain and work any tramways, railways, telephone or telegraph lines, electric lighting and other works, &c. The subscribers (with one share each) are:—W. Martin, Avondale Road, Manor Road, Richmond, gentleman; R. W. Brown, 79, High Street, Beckenham, journalist; A. J. Swan, 124, Peckham Rye, S.E., gentleman; E. T. Rouse, 1, Avenue Gardens, Mill Hill Park, W., accountant; G. F. Barnett, 12, Weston Park, Crouch End, N., clerk; C. Field, 27, St. Margaret's Road, Brockley, S.E., clerk; A. W. Rogers, 8, Denning Road, Hampstead, N.W., clerk. The number of directors is not to be less than three nor more than nine; the subscribers are to appoint the first. Qualification, £500; remuneration, £500 per annum divisible. Registered by Ashurst & Co., 17, Throgmorton Avenue, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Eastern Telegraph Company, Limited (6,338).—This company's return, made up to February 3rd, was filed on March 9th. The capital is £4,700,000 in £10 shares, of which 469,989 have been taken up. The full amount has been called and paid.

Pontypool Electric Light and Power Company, Limited (36,109).—This company's return was filed on March 25th, when 1,143 shares were taken up out of a capital of £10,000 in £5 shares. £5 per share has been called on 669, and £4 per share on 474, and £5,241 has been paid.

Birmingham Electric Supply Company, Limited (30,296).—This company's annual return was filed on March 28th, when the capital of £200,000 in £5 shares was fully taken up. £5 per share has been called, and £199,926 10s. has been paid, leaving £73 10s. in arrears.

Peru Telephone Company, Limited (56,290).—This company's return, made up to January 14th, was filed on March 8th. 7 shares have been taken up out of a capital of £100,000 in £5 shares, but no calls have been made.

Westminster Electric Supply Corporation, Limited (27,061).—This company's annual return was filed on March 10th, when the whole capital of £399,500 in £5 shares was taken up and paid for in full.

Cuba Submarine Telegraph Company, Limited (4,710).—This company's return was filed on March 9th, when the whole capital of £220,000 in £10 shares was taken up and paid for in full.

Anglo-American Telegraph Company, Limited (2,891).—This company's return was filed on March 23rd, when the whole capital of £7,000,000 stock was fully paid up.

Charing Cross and Strand Electricity Supply Corporation, Limited (29,122).—This company's return was filed on March 24th, when 49,999 shares were taken up out of a capital of £250,000 in £5 shares. £5 per share has been called, and £249,996 paid. £1 has been paid on a forfeited share.

St. James's and Pall Mall Electric Light Company, Limited (26,015).—This company's return was filed on March 15th. The capital is £300,000 in 100 founders' shares of £1 each, and 39,980 ordinary and 20,000 preference shares of £5 each. 100 founders', 31,980 ordinary and 20,000 preference have been taken up, the full amount called, and £260,000 paid.

National Telephone Company, Limited (15,066).—This company's return was filed on April 6th. The capital is £4,000,000 in 150,000 first preference shares of £10, 150,000 second preference shares of £10, 250,000 third preference shares of £5, and 490,000 ordinary shares of £5 each. All these shares, except 5,403 ordinary have been taken up, and 28,284 third preference and 44,413 ordinary are considered as paid. The full amount has been called on the others, and £3,609,500 has been paid.

Scarborough Electric Supply Company, Limited (37,569).—This company's return was filed on March 10th. 4,000 shares have been taken up out of a capital of £50,000 in £10 shares, and £9 per share has been called. £35,967 has been paid, and £33 is in arrears.

G. R. Blot & Co., Limited (54,459).—This company's statutory return was filed on February 24th. 30,693 shares have been taken up out of a capital of £75,000 in £1 shares, of which 14,400 are considered as paid. The full amount has been called, and £16,293 received on the rest.

CITY NOTES.

The Oriental Telephone and Electric Company, Limited.

The report of the directors for the year ended December 31st, 1897, to be presented at the fourth ordinary general meeting of the company, to be held at the Cannon Street Hotel, London, on Wednesday, April 27th, 1898, at one o'clock p.m., states that the revenue account shows a balance to credit of £10,909 18s., transferred to profit and loss, and including £829 14s. 3d. brought forward from 1896, and after deduction of £2,858 8s., representing the interim dividend of 4d. per share paid on October 30th last, there remains £8,681 4s. 3d. to be dealt with. The directors recommend the appropriation of this sum as follows:—£5,716 16s. in payment of a final dividend of 8d. per share, free of income-tax, making 5 per cent. for the year; £1,000 to extinguish the balance at debit of Colombo Exchange "suspense account"; £1,000 to reserve fund; and to carry forward £964 8s. 3d. The revenues of the Indian companies continue satisfactory. The Bombay Company has paid a dividend of 6 per cent., as against 5 per cent. for 1896, and has reserved from profits of the year a further sum of Rs. 30,000, which has been deemed desirable, in consequence of the continuance of the plague in that city and the unsatisfactory outlook in connection therewith. The Telephone Company of Egypt has declared, as hitherto, a dividend of 6 per cent. on its preferred shares, and the business still continues to develop. The China and Japan Telephone Company has paid its debenture interest, and makes fair progress both at Shanghai and Hong Kong. The electric lighting branch of the Company's business, carried on at several of its stations, has paid its way for the past year, and the current year opened with a fair amount of business in hand. In accordance with the articles of association, Mr. Lloyd and Mr. Frost retire at this meeting. Mr. Lloyd offers himself for re-election; Mr. Frost does not do so. The auditors, Messrs. Deloitte, Dever, Griffiths & Co., also retire, and offer themselves for re-election.

The Great Northern Telegraph Company of Copenhagen.

The working accounts for the year 1897 states that the net receipts during 1897, including the balance brought forward from 1896, amount to £332,474 11s. 2d., exclusive of interest on the investment of the reserve and renewal fund, which has been credited direct to this fund. Deducting £39,361 2s. 3d. for interest and authorisation of debentures, and £75,000 for interim dividends (already paid), there remains a balance of £218,113 8s. 11d., which the board proposes to distribute as follows:—Extra dividend (making the total dividend for the year 10 per cent.), £75,000; reserve and renewal fund, £77,777 15s. 6d.; pension fund of the staff, £2,777 15s. 7d.; directors' remuneration, £1,500; balance to be carried forward, £61,057 17s. 10d.

Indo-European Telegraph Company.

The ordinary general meeting of this company was held on Wednesday at Winchester House, Mr. J. Herbert Tritton presiding.

The Chairman, in moving the adoption of the report, expressed regret at the death of Mr. Earle. He said Mr. T. W. Andrews had been elected to the board in Captain Earle's place. The business compared very favourably with that of last year. The revenue had increased by £7,000. They had made last year certain concessions, and as a result they had not sustained any loss. It was probable there would be an increase in expenditure during the coming year—for instance, they were going to put down another wire between Warsaw and Odessa, permission having been granted by the Russian Government. They were also making some alterations in Persia. They had adopted the automatic Wheatstone apparatus with satisfactory results. The line had been working for 30 years, and there had been great improvements, but more were possible, especially in the wild country of the Caucasus. Mr. T. W. Andrews had been all over the line, and was satisfied with its condition. Replying to a question as to what would happen in the event of a war between England and Russia, the chairman said that he could not say what might happen to them, but it was agreed that their line was neutralised.

The report was adopted.

Calcutta Tramways Company, Limited.

At the ordinary general meeting held on Tuesday at the offices, 11, Abchurch Lane, Mr. E. C. Morgan, in moving the adoption of the report, said that the negotiations proceeding with the Calcutta Corporation last year for the use of mechanical traction had not, he was sorry to say, been brought to a satisfactory conclusion. In December last a proposal was received from the Corporation, but it was of such a nature as to render its acceptance impossible. A reply had been forwarded by the directors in which they stated that if the Corporation were prepared to agree that electric traction by the overhead trolley system should be applied to the Calcutta tramways, and any extension of the present system, and to give every necessary and reasonable facility for its introduction and use, the board would be prepared to recommend the shareholders to sanction an agreement by the company with the Corporation to the following effect:—(1) That the perpetual rights of the company to the tramways under the existing concession, unless purchased by the Corporation at 140 per cent. on the capital invested, be surrendered, and that, in lieu thereof, (2) the Corporation should have the right, on giving six months' previous notice in writing to purchase the tramways at the end of 42 years from January 1st, 1901, or at the end of any 10 years thereafter, on paying the company in cash 25 years' purchase of the average profits of the undertaking during the last three years of the term; (3) that the company would take at its own charge the necessary steps for applying electric traction to the tramways without asking the Corporation for any other concession or alteration of the existing concession, and would provide all the means necessary for that purpose, and pay Rs.30,000 annually by way of track rent throughout the term of the concession. This reply of the directors had been referred by the Corporation to a committee, which, so far as the board knew, had not yet met. If the Corporation continued to let the matter drag on, the directors proposed to represent to the Lieutenant-Governor of Bengal the actual state of affairs, and ask him to bring some pressure to bear on the municipal authorities, because it was impossible for the board to keep their offer open indefinitely. In the meantime their traffic had so far improved that they would be able to go on working the line satisfactorily with horses.

Submarine Cables Trust.

The report of the trustees for the year to 15th inst., to be submitted to the annual meeting of the certificate holders to be held in London on 27th inst., states that the revenue for that period, including the balance of £159 brought from the previous accounts, amounted to £23,156. During the past year the following coupons have been met:—Due April 15th, 1897, paid 10s. balance July 15th, 1897; due October 15th, 1897, paid £3 in full on due date; due April 15th, 1898, paid £3 in full on due date. The expenses of the trust amounted to £1,150, and the payments on account of the coupons to £21,976, together £23,136, leaving a balance of £20 to be carried forward. The trustees, in accordance with reasons given in last year's report, have sold the balance of their holding (£69,200) in Anglo-American Telegraph Company, Limited, deferred stock, and by a unanimous resolution of the trustees passed at a meeting called with express notice of the object, at which all the trustees were present in person, decided to invest the proceeds of such sale in the purchase of other securities of the character mentioned in the deed of trust. The certificate holders will be asked, in accordance with the provisions of the deed of trust, to confirm the resolution of the trustees and sanction such investments.

Apostoloff Automatic Telephone Parent Syndicate.—Mr. J. W. Cohen, of 13 and 14, Abchurch Lane, E.C., the liquidator of this syndicate, has declared a first dividend at the rate of 10s. in the £ upon the amounts of the respective debts of the creditors of the company whose debts have been admitted and proved. The liquidator states that there will be more than sufficient to pay creditors 20s. in the £, which payment he hopes to complete shortly.

Rand Central Electric Works, Limited.—This company announces that warrants for the dividend at the rate of 6 per cent. per annum for the period ended December 31st last have been posted to the shareholders registered in the books of the company as on March 31st.

Stock Exchange Notices.—The Committee has been requested to allow Chelsea Electricity Supply Company, Limited—Further issue of 8,000 ordinary shares, Nos. 32,501 to 40,500, to be quoted in the Official List.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending April 15th, 1898, were £3,278 4s. 4d.; corresponding period, 1897, £2,219 7s. 7d.; increase, £1,058 16s. 9d.

The City and South London Railway Company.—The receipts for the week ending April 17th, 1898, were £945; week ending April 18th, 1897, £845; increase, £100; total receipts for half-year, 1898, £16,771; corresponding period, 1897, £16,684; increase, £87.

The Cuba Submarine Telegraph Company.—The receipts for the month of December were £4,595, as compared with £3,818 in the corresponding month of last year.

The Dover Corporation Electric Tramways.—The receipts for the week ending April 16th, 1898, £180 7s.; total receipts to April 16th, 1898, £1,695 4s. 2d.

The Dublin United Tramways Company.—The receipts for week ending Friday, April 15th, 1898, were £3,338 9s. 2d.; corresponding week last year, £2,640 9s. 9d.; increase, £697 19s. 5d.; passengers carried, 588,181; corresponding week last year, 456,784; aggregate to date, £40,629 4s. 7d.; aggregate to date last year, £37,726 4s. 7d.; increase to date, £2,903; mileage open, 34 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending April 17th, 1898, amounted to £1,736; corresponding week last year, £1,478; increase, £258. 1898, includes Easter Monday. 1897, includes Good Friday and Easter Sunday.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending April 15th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company Limited, were £2,030.

SOME RECENT IMPROVEMENTS IN ACCUMULATORS AND THEIR APPLICATION TO TRACTION ON COMMON ROADS.*

By J. T. NIBLETT.

(*Concluded from page* 522.)

Probably no individual type of secondary cell will be found to answer for the very varied and ever-increasing purposes to which this class of apparatus is now being applied, and it follows that some form of specialisation must occur.

For central electric light stations, or for such work as levelling up the loads on electric tramways, where moderately constant work is required, a battery whose weight is large, or whose bulk is great, may be safely used. For self-contained electric light installations, weight and space occupied by the battery is of some moment; and where intermittent charging only is resorted to, absence of local action is desirable. The battery, under these circumstances, may have to stand idle for considerable periods, and it would not do for it to lose its charge while thus waiting. For traction purposes, where charging each day, or even several times per day, may be practised, local action is not such an objection, and the loss sustained thereby may be neglected. For some forms of vehicles, such as broughams, dog-carts, tricyles, and the like, which may be only occasionally required, and may have considerable waits between the periods of use—waits which may extend over days and even weeks—the absence of local action is essential. A fifth class of apparatus in which storage batteries are now playing a most important part is that of self-contained portable electric lamps, so largely used for medical and other purposes. In this case absence of local action, lightness, and compactness, together with great mechanical strength, is absolutely essential. In many cases such lamps are required to hold their current for many months, and this can only be obtained where there is little or no local action. Again, as the plates used in these small batteries are of small dimensions, the form of construction may be such as is not permissible in any other class of apparatus.

"Local action," it may be explained, is the term given by electricians to that frittering away of energy which frequently occurs while a cell is at rest. This wasting is experienced in nearly all forms of primary cells, and in many types of secondary cells. In the case of secondary cells it is due to the establishment of voltaic couples between the metal support and molecules of lead salt when in the presence of sulphuric acid and water. This troublesome complaint leads to the destruction of the peroxide and the formation of sulphate of lead, and it not only reduces the capacity of the cell, but it frequently leads to its ruin. In the Planté cell, with its large metal surface and thin layer of active material, local action is far more prevalent than in the Faure, with its comparatively smooth and small metal surface and thick masses of lead oxide.

To accurately test a storage cell is no easy matter, and unless great care is exercised very fictitious results may be obtained. A laboratory test as a preliminary may be very well, but for practical results such tests should not be relied upon. Testing under actual working conditions, and for an extended period, is the only reliable means of ascertaining the capabilities of cells intended for traction work.

To obtain a capacity test by discharging through a constant resistance, noting the fall of current and potential, is quite easy of manipulation, and is much used when comparative tests only are required. A more reliable method, however, is to discharge at a constant current, stopping when a prescribed fall of potential occurs. For traction work, where a uniform output for a given number of hours is required, it is very much the best plan to take the capacity of the cell in terms of watt-hours. Under these circumstances the discharging rate in watts must be kept constant. Testing for local action, noting the effect of high rates of charge and discharge, are more serious matters, and require careful manipulation.

The internal resistance of a cell depends upon the total active surface area of the opposing plates, the nature of the electrolyte and its condition and temperature, and the distance between the plates.

There are many methods for determining the internal resistance of batteries. If the cells be as nearly as possible of the same dimensions, capacity, and state of charge, then two cells may be placed in opposition (poles of like polarity joined together) and their joint resistance may be measured by the ordinary Wheatstone bridge method. If the cells be exactly similar, then one-half the resistance indicated will represent the resistance of each cell.

A far more reliable and accurate means of ascertaining the internal resistance of cells is the differential method, as expressed by the following formula:—

* Abstract of paper read before the Self-Propelled Traffic Association, Liverpool Centre, on March 29th.

$$r = \frac{D - D'}{D} R$$

where r is the resistance required, D and D′ are the values of deflections obtained on a high-resistance sensitive galvanometer, and R expresses the value of a small but known resistance, used as a shunt.

When making tests by this method, a high-resistance potential galvanometer should be used, and one whose scale readings are either of uniform value, or whose tangents are strictly proportional to the angle of the deflections. To determine r we have to obtain a deflection, D, when the cell is on open circuit, and then obtain another reading, D′, when the cell is shunted by R, then by the formula given the internal resistance may be ascertained. The shunt resistance, R, should be small in comparison with the galvanometer coils. Good results may be obtained if the resistance of the galvanometer is, say, 5,000 ohms, and the shunt not more than 1 to 5 ohms.

The total current, or energy capacity, of a storage cell is the maximum amount of current or electrical energy which it is capable of storing, without reference to any loss that may occur by it being allowed to remain idle, nor does it take into account the rate or manner of its discharge.

The working current, or energy capacity, is that amount of current, or electrical energy, which can be obtained from the cell at any specified rate of discharge. When estimating this, the discharge is always stopped as soon as the cell ceases to do useful work. The working capacity of storage cells may vary between very wide limits.

The absolute current, or energy efficiency, of an accumulator cell is the ratio between that amount of current or energy put into it and that obtained by a total discharge, without reference either to its rate of charge or discharge, or to the time allowed to elapse between these operations.

The working current, or energy efficiency, of a storage cell is the ratio between the value of the current or energy expended in the charging operation, and that obtained when the cell is discharged at any specified rate.

In a lead storage cell, if the surface and quantity of active material be accurately proportioned, and if the discharge be commenced immediately after the termination of the charge, then a current efficiency of as much as 98 per cent. may be obtained, provided the rate of discharge is low and well regulated. In practice it is found that low rates of discharge are not economical, and as the current efficiency always decreases as the discharge rate increases, it is found that the normal current efficiency seldom exceeds 90 per cent., and averages about 85 per cent.

As the normal discharging electromotive force of a lead secondary cell never exceeds 2 volts, and as an electromotive force of from 2·4 to 2·5 volts is required at its poles to overcome both its opposing electromotive force and its internal resistance, there is clearly an initial loss of 20 per cent. between the energy required to charge it, and that given out during its discharge. The normal discharging potential seldom exceeds 2 volts, and as this pressure is continually being reduced as the rate of discharge increases, it follows that an energy efficiency of 80 per cent. can never be realised. As a matter of fact, a maximum of 75, and a mean of 60 per cent., is the usual energy efficiency of lead-sulphuric-acid storage cells.

What the ordinary commercial man will be most interested in are tests which give him reliable information at to the cost of the up-keep and life of the battery; also data as to the initial cost, and as to the mode of it doing its work. Such information cannot be obtained in a laboratory, and has to be obtained by actual trials.

We have already shown that no one type of cell is capable of doing all the very varied kinds of work accumulators are now called upon to do. Before building up a battery, it is, therefore, wise to ascertain definitely the class of work it is intended to do, and construct accordingly.

Perhaps a short description of one or two of the present applications of secondary batteries for propelling motor cars will best serve to show the usual method of practically dealing with them.

In this country, the vehicles put upon the London roads by the London Electrical Cab Company may be looked upon as a pioneer enterprise, and its development will be watched with the closest interest by all those concerned.

The battery used is a special Faure-King type, and is supplied and maintained under contract by the E.P.S. Company. The plates used are thin, and to prevent the active material being "washed" out, the surfaces are covered with a layer of silicated asbestos held in position by thin sheets of perforated vulcanite. The whole of the cells are mounted in a tray, which is slung underneath the cab by four suspending links. These links are supported by springs under compression, and, as an extra safeguard against vibration, the ordinary carriage springs again support the battery tray. The total weight of the battery is 14 cwt. The total weight of the complete vehicle, including driver and its full complement of passengers, is approximately 30 cwt.

The battery consists of 40 cells, and, as previously stated, it weighs complete about 14 cwt. The capacity of each cell is 170 ampere-hours at a normal discharging rate of 30 amperes. The electrical pressure at the battery terminals is 80 volts. Thus the battery has a storage capacity of 13,600 watt-hours at a discharging rate of 2,400 watts, or about 3¼ electrical H.P. When fully charged the battery is said to be able to run the cab a distance of 50 miles over the ordinary London streets. The mean current drawn from the battery when on a level road is 30 amperes, on rougher road from 40 to 45 amperes is required, while climbing steep gradients the cells are called upon to give as much as 120 amperes. The motor, although constructed to give a normal output of 3 H.P., is capable of a maximum of 4 H.P. without unduly heating, so that a margin of 25 per cent. is obtained for eventualities.

In New York some electric hansom cabs have recently been put on the roads. The cabs are made by the Electric Carriage and Waggon Company. In some respects they resemble our London hansoms, but the vehicles are fitted with four wheels instead of two. The back wheels are used for steering and the front for driving. The chief feature of this cab is that two motors are used, one for each of the driving wheels. By employing two motors, various variations of speed can, of course, be obtained by running them in parallel or series; and by having each wheel under separate control, quicker turning power of the vehicle can probably be obtained. This is doubtless the object the designers of the New York hansoms had in view, although it is very problematic if any very real advantage is gained by such an arrangement, unless it be used in heavy vehicles such as coal lorries.

The New York cabs are said to weigh 3,000 lbs. Each motor develops 1½ H.P. with 75 volts, and at a speed of 800 revolutions per minute. This represents a speed of 8 miles per hour for the vehicle. The battery used consists of 44 cells placed in trays containing 11 cells in each. The four sections are placed in a receptacle in the rear of the vehicle. No loose terminals are used, contact between the sections and other parts being established by means of plates and contact springs. Each cell contains three plates of the chloride form, and they have a useful capacity of 100 ampere-hours when discharged at 21 amperes—the normal rate. The whole battery weighs 900 lbs. Speeds varying from 4 to 15 miles per hour can, it is said, be obtained with varying battery discharges of from 12½ to 40 amperes.

L'Electrique Société Anonyme of Brussels have recently introduced an electrically propelled dog-cart. In this vehicle, and according to the usual practice, the battery cells are placed underneath the seats. 48 cells of the Planté type, having a capacity of about 75 amperes, are used. The total weight of the battery is 850 lbs. The motor is wound with the coils of the fields and armature in series, and it weighs about 260 lbs. A speed of 1,750 revolutions per minute is attained with a battery discharge of 21 amperes. The motor is connected to the driving wheels by reducing gear and chain bands, while differential movements of the driving wheels are obtained by the use of an intermediate clutch.

The dog-cart has four wheels, and is made to seat four passengers, including the driver. The carriage, including batteries, motor, and gearing, weighs, complete, about 2,500 lbs. The maximum speed is 10 miles per hour, and at this rate it is stated a distance of from 40 to 50 miles can be travelled with one charge of the battery.

As a means of regulating speed in a self-contained motor car, actuated by batteries, two methods are at present in vogue. The first is by splitting up the battery into sections by a suitable commutating arrangement, thereby putting the sections either in series or parallel, as required. The objection that may be raised to this plan is that the cells may be unequally discharged. A more practical method, and one adopted on the London cabs as explained, is using the battery as a complete unit, and obtaining the various speeds by commutating the coils in the fields and armatures of the motor. It is possible that some method may be adopted, by which the motor may be run at constant speed, while the speed variations in the car are obtained by suitable gearing. According to present practice the motor, when starting the vehicle, is running slowly, and therefore in its most inefficient condition. If the constant speed idea were utilised, the motor might be of smaller power, and it could also be run at a higher and more uniform efficiency.

For the Paris electric cabs Messrs. De Puydt & Poncin, of Birkenhead, are supplying some special motors, which appear to compare favourably with those used in our London cabs. It is stated that these motors, which weigh only about 170 lbs., will develop 8·5 H.P. for 20 minutes, or 4·5 H.P. for continuous running, without any undue heating or sparking. The normal speed is given as 1,700 revolutions per minute, and a commercial efficiency of 81 per cent. is said to be obtained.

As regards the prevailing method of connecting the motors to the driving wheels by the system of gearing, probably with our present knowledge it is the best that can be done. Some way of dispensing with gear and running direct will probably be devised. If this could be done, not only would it lead to great economy in working, but it would greatly add to the comfort of the passengers. When riding, for instance, in one of the London electric cabs, in addition to the hum of the motor, which is not at all unpleasant, one's ears are assailed by the clanking and rattling of the gearing and chain. If direct running or some more silent method of gearing could be devised, it would be a desirable improvement. Improvements in the wheel tyres will doubtless be made, and such improvements would tend to reduce road friction, and thereby save power or give increased speed. They would also reduce the depreciation in the working parts and give the battery a better chance.

Methods of electric locomotion on common roads present enormous possibilities. Electrically-propelled omnibuses, broughams, dog-carts, and light parcel delivery vans may now be seen running along our thoroughfares. There is no reason why the same plan should not be adopted for driving vehicles for the cartage of goods generally. In the latter case appearance need not be studied to such an extent as in the passenger-carrying conveyances; therefore, in this case the electrical engineer would have a freer hand, and better results might be anticipated.

Methods of recharging will have to be seriously considered. There seems no reason why, in all our large towns, charging centres should not be established. The ordinary cab is stationary a great part of the day, and there seems no valid reason why the charging operation should not be rendered so simple that a cabman of ordinary intelligence could easily perform it. With an "in-and-out" electricity meter placed on the vehicle in a convenient position on the battery circuit, the driver could see at a glance how much energy had been put in and taken out of his battery; therefore, would know when a recharge is required; also, when charging, by reference to the meter, he could see when his battery is satisfied. Such a measuring instrument, with the small range required, need not be an expensive addition. A supply system, worked on the penny-in-the-slot principle, could easily be arranged. The battery, of course, would not be removed, but would be connected up to the source by suitable flexible mains. Under these conditions the driver could buy his supply of electricity much in the same way as a carman can now buy fodder for his horses.

The form of battery required for driving a self-contained motor car over common roads may need to be of a different nature to that required in cars running on a permanent way, where the tractive force remains more nearly constant, and where there is less jolting and vibration. Possibly some form of mechanically solid cell with a Faure type negative and a Planté type positive element will fulfil the requirements.

As to the probabilities of the self-contained electric motor car comparing favourably with horse haulage, this will entirely depend upon its economic aspect. However great the convenience of electric haulage, however great its reliability, ease of manipulation, sanitary aspect, and general convenience, the question as to whether it is best or not has still to be satisfactorily answered. In its present experimental stage trustworthy figures of the daily or weekly cost of up-keep cannot be expected. It is only by taking the average expenses incurred during months or years that anything like an accurate estimate can be arrived at. The initial cost and cost of maintenance of the batteries employed will, we believe, be the controlling factor. Whatever turn the idea of electrically propelled motor cars may take, it must necessarily always involve the use of some apparatus for storing and giving out electrical energy.

The modern secondary battery leaves very much to be desired, but still there are several very good batteries for this purpose obtainable, and these may serve to tide the electric traction man over the period intervening before the advent of the ideal cell which we all wish to see.

ELECTRIC LIGHTING OF MAIL COACHES.

Some interesting particulars have been published concerning the electric lighting of German mail coaches. The *Elektrotechnische Zeitschrift*, which discusses the subject in a recent editorial, states that the 15-volt lamps employed for this purpose are of 12 candle-power and are replaced by others after being in service for 200 hours, notwithstanding the fact that the filaments are still intact. The glass bulbs are tolerably larger in order to delay the blackening of the bulbs as much as possible. As the lamps are arranged in suitable positions before the Post Office officials, a greater illumination of the working places is obtained than with intensive gas burners suspended from the roof behind the sorters.

In the case of the 12-metre mail coaches a battery of 32 cells of the Boese type is used, whilst the coaches 10 metres long are equipped with 16 cells arranged in four boxes. The weight of the 16 cell battery, which has a capacity of 120 ampere-hours, is 184 kilogrammes; but in a newer type with the number of plates reduced from 9 to 7 per cell, the weight has been diminished to 172 kilogrammes.

At the present time the re-charging of the batteries is effected at 18 depôts, and three further charging stations are now being erected. Where the railway administration possesses a charging station of its own, the batteries are connected in series of 16 cells, or from boxes to omnibus bars between which there exists a pressure of 45 volts. If the current is obtained from municipal supply works, the pressure as a general rule ranges from 100 to 110 volts, and in some cases, as at Breslau, it amounts to 220 volts. In these instances a lot of useful energy would be dissipated in resistances unless a larger number of cells were simultaneously charged in series. The batteries delivered at a charging station are, however, not all in the same condition, and for that matter it would be impracticable to select and group them according to their electrical condition. As a result the inconvenience arises that highly exhausted batteries do not receive a sufficient re-charge, whilst those slightly exhausted receive too much; hence the life of the plates is injuriously affected.

In order to overcome this difficulty, Post-Inspector Argrath has suggested a method whereby each battery, where the pressure between the bus bars at a charging station is too high for the purpose, only receives a charge of current at a pressure of about 45 volts, or at that pressure required by the condition of the battery. This object is attained with a current at a pressure of 100 volts by the employment of a middle bus bar between which and the outer bars the batteries are connected in a manner similar to the Edison three-wire system. If the number of batteries on both sides of the middle bar is the same and the batteries are all in the same condition, only about 5 volts has to be absorbed in each charging conductor by the rheostats, which must be used in any case for each battery. Should, however, these conditions not be fulfilled, the pressure on one side of the middle bar will be higher than that on the other unless a special means of artificial compensation is provided. This is now attained by the use of a main rheostat which can be arranged on one or the other side of the system. This rheostat is placed parallel to the batteries on the side of higher pressure, and so arranged that the requisite compensation is effected. When the current available has a pressure of 200 volts, it is provided that the above arrangement shall be doubled.

It has been possible to ascertain some figures concerning the cost of lighting 627 mail coaches in this manner from nine charging stations, which have been in operation for over a year. After providing 4 per cent. for interest on capital and 10 per cent. for redemption (20 per cent. for the batteries), the lamp hour with a 12 candle-power lamp works out at 3·52 pfennige (·42d.) This compares with 4·53 pfennige (·54d.) in the case of gas lighting, showing a difference of nearly one pfennig in favour of electrical illumination.

ELECTRICITY IN CHEMICAL WORKS.

Although power in chemical works does not occupy so important a position as it does in other industries, for instance in the textile industry, where the whole of the transformation is effected by mechanical means, it, nevertheless, plays an important part in numerous subsidiary operations, such as grinding, pulverising, pumping, compressing air or other gases, actuating cranes, hauling, &c. And so great is the competition in all chemical manufactures, that it becomes a matter of prime importance to determine what shall be used as a source of energy, whether steam, gas, electricity, or water. At a recent meeting of the Manchester Section of the Society of Chemical Industry, Dr. Bowman examined this question to some extent, but we do not think that he has dealt with the subject so exhaustively as it deserves. He has much to say regarding the use of steam, and gives some very interesting figures respecting the efficiency of this agent. The efficiency of the gas engine is also considered briefly, and data are given, but electricity is dismissed as impracticable, and those who read the paper are not likely to be convinced because the statement is merely supported by Dr. Bowman's opinion. If the paper were to be a useful contribution to an important subject, comparisons between gas, steam, water, and electricity should be properly drawn, data should be given for each source of power, which should be entirely comparable. This Dr. Bowman has failed to do entirely, and the matter is in the same position as it was before he touched it.

Of course, it is advisable to avoid mechanical operations as much as possible in chemical works, and when they are necessary the machinery should be simple. Chemical works abound in dust, dirt, gases, and liquids which injure the machinery, and we agree with Dr. Bowman that it is advisable to use the very simplest forms of engine which can stand the wear and tear to which they have to be subjected. Then again, chemical works usually cover a large area of ground, and operations are rarely simultaneous, and the general practice is to rely upon small independent engines—a very bad plan indeed, for even under the best conditions the steam engine is a wasteful machine. In large chemical works power has to be distributed over miles of pipes exposed to the condensing action of the air, which of itself accounts for a very large percentage of inefficiency. Indeed, Dr. Bowman himself admits a doubt whether, in many of the small engines, more than 5 per cent. of the power originally in the fuel is actually used. In addition to all this, steam is not a good vehicle for obtaining power, because it can never be a perfect gas unless absolutely dry, and the moment it begins to expand—which it must do if worked economically—it ceases to be a dry gas.

Although these considerations seem to point directly to electrical distribution as the most economical method of working a chemical factory, Dr. Bowman contends that it is almost impossible, for dust and gases have a marked effect on conducting wires and electric motors. He says that lead-covered wires, even with a coating outside, are eaten through in a short time, and except where motors can be enclosed in special rooms or boxes, and conducting wires kept out of reach of corrosion, electric distribution of power is not suitable for chemical works. It seems to us that this form of distributing energy should not be so jauntily dismissed. It is quite true that there are many difficulties in the way; a manufacturer does not like to risk having his installation worn out by corrosion shortly after he has laid it down. But have we probed all the possibilities? We wonder in how many instances electric distribution has been tried with such disastrous consequences as Dr. Bowman seems to imply would necessarily follow. Surely it is possible to place the generating plant in some part of the works, which, as Dr. Bowman says, are always large, where it can be safe from corrosive gases; or the construction of a special building, with double doors and windows, ought not to be impossible. If either of these two courses can be successfully observed, then the problem of protecting the wires ought not to be insurmountable, whilst the motors themselves could surely be enclosed in special rooms or boxes. We do not think that Dr. Bowman has made out a bad case against electric distribution in chemical works, for he has simply dismissed it with a meagre statement of difficulties and a strong statement of his own opinion.

On the other hand, he concludes his paper with a remark that electric distribution can best be applied in chemical works to lighting. He says that at least twice the quantity of light can be obtained by the arc lamp than by burning gas or even Wells's light, and, finally, he says that to compete with steam as the motive power, electricity must be supplied at not more than ½d. per Board of Trade unit, or half this cost to compete with gas. These latter, however, are statements which are entirely unsupported by comparative data, and we are invited to accept Dr. Bowman's opinion. Thoughtful people will require a good deal more than that, and we hope that the attention of electrical engineers will be aroused by these statements, and that some comparative data may be obtained from an actually working installation.

As regards electro-chemical processes, the conditions are somewhat different from those obtaining in chemical works generally; but we shall await with interest Dr. Bowman's promised paper on the subject. We hope that it will be more copiously illustrated with facts than his present paper.

ELECTROLYTIC TREATMENT OF SLIMES.

If we were asked what among the applications of electricity is the one which seems the most remarkable, there would be a majority in favour of wireless telegraphy, which, however, has not yet come into general practice, and is only just emerging from the experimental stage.

The admirers of X rays, and those of the utilisation of the Niagara Falls energy, would be numerous; but for an electro-chemist, and especially an electro-metallurgist, the solution of the problem of the economic extraction of gold from slimes, that clayey mass through which no solution can percolate, looks as if it were most decidedly the greatest achievement accomplished in the electrical world.

Mr. Charles Butters in his valedictory address to the Chemical and Metallurgical Society of South Africa, of which he is the president, described the treatment of the slimes, in which, up to the present, large treasures were buried and considered as lost for ever.

Ten years ago, the great question was to extract the gold from the heaps of tailings which were lying as barren sands. To-day, it is the turn of the slimes, with this difference, that gold can be recovered from tailing solutions by means of zinc, although not so well as by the electric current, while the precipitation of gold from an extremely weak cyanide solution is quite an easy operation by electrolysis, but cannot be effected by zinc shavings.

This question is of so much importance to the mining industry that it marks an epoch in the metallurgical world that is well worthy of consideration.

It was only the production of such gold-bearing material as tailings, and the enormous quantities in which they were produced that brought the necessity of the treatment of tailings before the public in a very marked degree; and in the same manner the enormous production of slimes, their storage and value, demanded an economic method of treatment.

It was found that if they were allowed to be deposited in dams for a comparatively short time, even for a few days, decomposition of the pyrites took place, and the question of their treatment directly as received from the mill thus became a subject for study. These researches have successfully resulted in the working out of a practical method which consists essentially in the coagulation of the slimes in battery water, by means of lime, their concentration by spitzkasten, and final settlement in continuous overflow vats or pits. The coagulation of the particles in clayey soils in agricultural operations by the addition of lime has long been known and practised, and the use of lime for the flocculation and precipitation of the slimes suspended in battery pulp is but another adaptation of the same principle.

General Features of the Slimes Problem.

"In slimes, says Mr. Butters, we found a substance which could not be backed, or through which the solution would not percolate, but which we were obliged to wash per decantation. With decantation, the washing of the material takes place by dilution, one wash does not displace another wash, but simply mixes with it; and since the amount of solution or wash which this clayey mixture retains is from 40 to 50 per cent., the amount of dilution necessary to extract a satisfactory percentage of the gold necessitates the use as washes of from 6 to 8 tons of liquid per ton of slimes treated. Consequently, in sand treatment, where 4 dwts. are extracted from 1 ton of sand, with 2 tons of solution, the average value of the solution is 2 dwts.; while in slimes treatment, if 4 dwts. are extracted from 1 ton of slimes, the average value of the solution would be 12 grains. In the case of the sand, the value of the first solution leached off might easily be 6 dwts., while with slimes, the first solution would probably not be over 1 dwt. The result is, that in the latter case you have a very large volume of much diluted solution to deal with, and at the same time the slimes retain a moisture nearly their own weight of solution. In order, therefore, that slimes may be economically treated, it is necessary to use a very dilute solution of cyanide, so that too much cyanide may not be lost with the residues when discharged, and that too much may not be decomposed during treatment. How to obtain gold from this solution presents an entirely new problem to the metallurgist. Dilute solutions containing from 0·01 to 0·001 per cent. of cyanide, and from 6 to 24 grains of gold per ton, had not hitherto been successfully handled."

The Solution of the Gold.

"The dissolving of the gold in fresh slimes is a comparatively simple matter in comparison with the dissolving of the gold in accumulated slimes. In fresh slimes, there are usually very few reducing or oxygen-consuming compounds, while in accumulated slimes there can be various substances which will absorb oxygen; and if we wish the cyanide gold-dissolving solution to act, oxygen must be present. In old slimes, decomposing organic matter, arising from different sources, as well as the various products of the decomposition of pyrites, are always present; all these substances have, in common, the property of absorbing oxygen in a more or less degree. Therefore, during the operation of dissolving the gold in old slimes, oxygen must be constantly supplied.

The principal of oxidation of the reducing substances in slimes by means of aeration, was put into practical use by Mr. W. A. Caldecott, who has given the reasons that render this operation specially necessary in the treatment of accumulated or acid slimes. This operation was first carried out at the Robinson slimes plant by the introduction of atmospheric air through a perforated pipe in the bottom of the vat containing the charge of pulp undergoing agitation. After preliminary oxidation of the pulp had taken place, in order to lessen cyanide consumption, cyanide was added, and aeration continued. It was found that the gold dissolved as readily by this method as in the case of fresh slimes."

The Precipitation of the Gold.

In the foregoing operations the ordinary methods of metallurgy have been reversed. In every other metallurgical operation, successive concentration is the means by which we finally obtain the metal for which we are working; but in this case we pursue the opposite course. The final operation of winning the gold takes place from a grade of material worth less per ton than was the material with which we started. We have simply changed the physical conditions of the gold from the state of a solid into that of a liquid, and it is with this diluted liquid that we have now to deal. Precipitations of metals from solutions present many curious and interesting problems, and one of these is, that with the same re-agents, it is very much more difficult to produce perfect precipitation from a very dilute solution than from a concentrated solution.

In electrolytic precipitation we have a different set of laws governing the electro-deposition of metals from those which operate in chemical precipitation. In the course of our experiments on the precipitation of dilute cyanide liquors, we have tried many methods of precipitating solutions containing 6 to 12 grains of gold per ton, but failed completely with such dilute liquor; whereas the same methods acted perfectly on 5 dwts. or 10 dwts. solution. With a solution of gold down to 6 dwts. per ton, which is about one part in 100,000, it would be natural to think if it was one part in 100,000, or one part in a million, or one part in 10 millions, there would not be a very great difference in the resistance of such very minute proportions of dissolved gold to precipitation, whether by electromotive force or by chemical reaction; but the difference between the action of a liquid containing 6 dwts. per ton and one carrying 6 grains per ton is most marked, both in chemical precipitation and in electrolytic deposition. In general, we have found that we could effect the precipitation of the gold in these dilute solutions best, and most economically, by means of electrolysis.

The principal points in electrolytic precipitation that it is desirable to study are the amount of current per square foot of anode and cathode, and the time the current is exerted, taken in conjunction with the value of the solution. One of the first points requisite in the electrolytic deposition of gold is that the liquor shall contain no solid matter; that is to say, that it will be absolutely clear.

The liquor from accumulated slimes contains a considerable amount of iron and lime salts in solution, and the settlement of the fine clayey particles is retarded. This may, possibly, also be due to the organic matter which it contains.

Other substances in the liquid which affect the surface of the cathode are those salts which are in solution upon entering the box, and are there deposited on the large surface exposed, or are electrolysed. Lime, which has been used for settlement, and also to neutralise acidity, is in the form of carbonate of lime, sulphate of lime, or hydrate of lime. This precipitates partly as carbonate and partly as sulphate upon the anodes and cathodes, more especially on the former, and is precipitated by means of the electrolytic current. Then there are the products of the decomposition itself, which (in the case of iron salts resulting from the decomposition of the pyrites in the ore) are separated in the form of Prussian blue and hydrate of iron. These, again, are the products of the decomposition of the anode plates.

The clearness of the solution depends largely on the solution of the anodes. The iron plate anode in use to-day in the Siemens and Halske boxes, with properly proportioned current, is a very perfect anode, easy to be obtained in any quantity, and as easily manipulated and secured in the boxes. With a current density as low as 0·03 or 0·04 ampere per square foot, very little decomposition of the iron anode takes place. An anode $\frac{3}{16}$ths of an inch in thickness and with a current density of 0·035 ampere per square foot, should last for five years, and possibly much longer. There seems to be a limit of current density up to which an iron anode will show very little corrosion; but beyond that point, oxidation seems to take place more rapidly than the proportionate rise of current density would indicate. Where the division and tension of the current has been very carefully studied and regulated, very little decomposition of the anode need take place.

With the peroxide of lead anode, which was discovered by Mr. Emile Andreoli in the early part of 1895, practically no corrosion of the anode takes place, and although, up to now, this anode has only been used in a small way, one is confident that its introduction into this country on a large scale would prove satisfactory. With perfectly filtered conditions, and with peroxide of lead anode working with fresh slimes, and by watching carefully the amount of lime added to the slimes, there should be very little trouble in maintaining a perfectly clear anode surface for the plating of the gold.

The subject of the production of suitable anodes for precipitation of gold from cyanide solutions is probably not exhausted, but the field has been very thoroughly explored by able electricians and chemists, and beyond the two anodes mentioned, we do not know of any that will fulfil the required conditions. The anode has attracted a good deal of study, but the subject of the cathode is not less interesting and important. Many substances have been tried, which have performed their functions more or less completely. Lead has been used in thick plates, in thin sheets, in ribbons or strips, and in the form of shavings, while zinc has been used in the form of amalgamated plates and as shavings; amalgamated copper plates have similarly been tried, together with iron plates and various other forms of iron; and the same with mercury. Zinc, copper and iron, in various forms have been utilised by Mr. Andreoli for this purpose. Mercury is in use in the United States in the Pelatan-Clerici process; on these fields, at present, lead strips and lead shavings are in use, and zinc shavings are used by Mr. Bettel at the Comet. Each of these various cathodes have their peculiar advantages. Lead strips are used everywhere in the plants using the Siemens process except at the Central works, where part of the boxes are charged with lead shavings.

We may look upon the slimes treatment as it has been developed in this country by the members of this society as a new metallurgical process, which will be adopted all over the world, and we think that its main features will be practically retained. The use of lime for settlement, the use of spitzkasten for collecting, tanks for "natural settlement," dissolving the gold by means of agitation or centrifugal pumps, the decantation of the liquid, and the precipitation by electrolytic method, are, probably, permanent features, which in detail may be modified to some extent, but which will remain with us.

SUBMARINE TORPEDO BOATS.

A paper dealing with the subject of torpedo boats and their influence on torpedo boat architecture, by Captain W. H. Jaques, was presented at the recent conference of the Institution of Naval Architects. The author, after referring to the four preliminary submarine boats built in the United States under the direction of Mr. John P. Holland, proceeded to describe the *Plunger* and the *Holland*, which are now receiving considerable attention in that country.

The boat constructed by the Holland Company for the United States Navy Department was named the *Plunger* by the Department, and was launched August 7th of last year at the constructor's yard in Baltimore. She is the fifth one designed by Mr. Holland, and is 84 feet long, of circular section, 11 feet 6 inches diameter, surface displacement 149 tons, submerged displacement 165 tons, with a reserve buoyancy of about a quarter of a ton. The guaranteed speed is 15 knots on the surface and 14 knots with her steam machinery while awash, with 1 foot of the turret above the water. Her totally submerged electrically running speed must be 8 knots for six hours.

There is a turret amidship with 4 inches of protection and a superstructure for a fair water. Two down-haul screws have been added, although they are not considered by Mr. Holland a requisite of the system. There are two openings in the nose-piece through which service-torpedoes are to be discharged. In addition to hand-gear for horizontal steering and diving, there are automatic devices for maintaining submergence at predetermined depths. A camera lucida has also been fitted. The hull has been constructed to admit a submergence of 75 feet. Some of the water-tight compartments serve as water-tanks; others contain oil fuel; others are employed for compensating discharged weights. A special device compensates for the oil consumed. There are four rudders, two for steering horizontally and two vertically, controlled by automatic devices. For running on the surface or awash, steam generated by petroleum is employed, while electricity from storage batteries is used under water. There is one water-tube boiler of the Mosher type of 3,000 square feet heating surface, fitted with a system of oil fuel capable of consuming 2,000 lbs. of oil per hour. There are two main, vertical, triple-expansion steam engines of 600 H.P. each, and one auxiliary of the same type of 300 H.P. The electric machinery is composed of one main motor of 70 H.P. for propelling the boat when submerged, operating either the side or centre shaft, or used as a dynamo for recharging batteries. There are additional electric motors for operating down-haul screws and performing other services as required. Air for tank and ventilation service is supplied from commercial reservoirs. There are special fittings for closing smoke pipe and air ducts quickly before submerging, and the tank operations are very simply controlled by Kingston and compressed air reducing valves. The *Plunger* has three propellers (in addition to the down-haul screws), any one, or all of which can be operated by either steam or electrical machinery.

The author then referred to the *Holland*, a smaller and similar type of boat, and proceeded to suggest the possibilities of such craft to take the place of second-class torpedo boats on battleships, and of semi-submerged boats of almost any dimensions, having armour enough above water to afford ample protection, at the same time protecting all the rest by water. In conclusion, he pointed out that the great need of the hour for harbour and coast defence is a small torpedo boat that can be submerged, having within it a storage battery of sufficient power to give it a submerged range of a few hours, with 9 or 10 knots surface speed, and from 6 to 8 knots submerged.

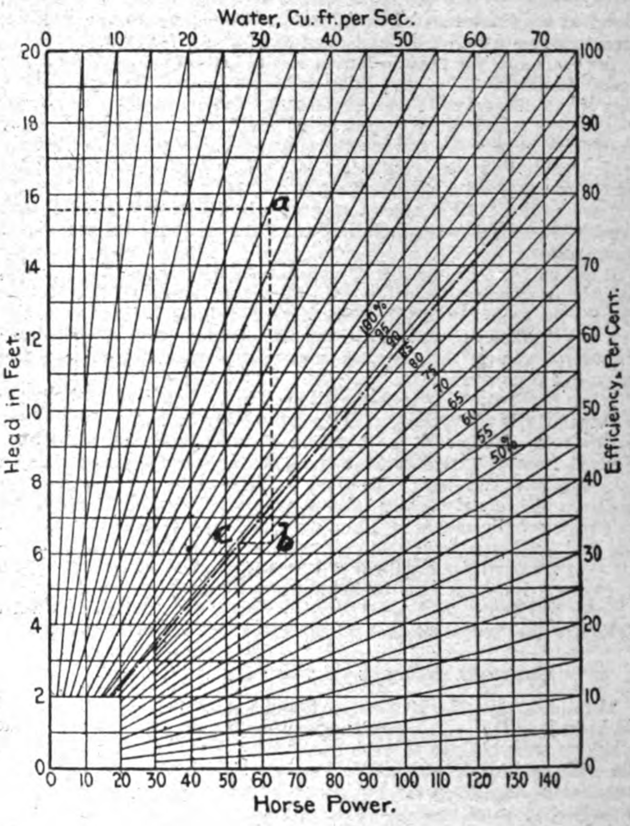
WATER POWER DIAGRAM.

The accompanying diagram, for which we are indebted to the *Electrical Engineer* of New York, is due to Mr. O. H. Landreth. It is a graphical representation of the formula, H.P. $= \frac{\text{H Q D E}}{500}$, where H is the effective head in feet, Q is the quantity of water in cubic feet per second, D is the weight of a cubic foot of water $= 62{\cdot}4$ lbs., and E is the percentage of efficiency of the wheel.

There are two sets of radiating lines from the left lower corner of the diagram. Those which pass to the top line are lines of supply; those to the right hand vertical line are efficiency lines, except the dotted line near the 90, which is a conversion line for horse-power. To use the diagram there is assumed as an example a head of 15·6 feet, at which a supply of 40 cubic feet per second is used in a wheel of 75 per cent. efficiency.

The following is the mode of using the dotted line showing the procedure: From the left vertical scale of head in feet, viz., at 15·6, draw a horizontal to touch the inclined line from the 40 cubic feet division on the top scale. From this point of intersection, *a*, drop a vertical to the inclined line from the 75 per cent. division of the efficiency scale. From this second point, *b*, draw a horizontal to the conversion line. From this final intersection, *c*, a vertical line to the lower scale shows the horse-power, 53·2.

The conversion line is drawn at such an angle from the vertical as makes the tangent $= \frac{1}{2}(0{\cdot}1134)\ 75\,\frac{v}{h}$ where v and h are the numerical values of the vertical scale of head and the horizontal scale of



quantity, the $\frac{1}{2}$ being introduced to make the scale of horse-power half the scale of the upper line of quantity, and the decimal 0·1134 being the coefficient in the formula H.P. = 0·1134 H Q E for horse-power on the basis of the weight 62·4 lbs. per cubic foot. For amounts of head and volume beyond the range of the scale, the figures may be used as though of tenfold value, or to any convenient other multiple, the final reading being similarly multiplied.

CARBON BRUSH-HOLDERS.

By ERNEST KILBURN SCOTT.

Part I.

Although Prof. Forbes first suggested using a block of fine grained carbon on dynamo commutators so long ago as 1885, practically nothing was done to develop the idea until about 1892. Since then, however, the carbon brush has rapidly pushed its way into favour until it threatens to oust the metal brush out of the field altogether.

As the published information on the subject is somewhat meagre, the writer proposes, in the following article, to give a few of the rules which govern the application of carbon brushes, and also to describe some of the leading types.

One point on which there is a lack of definite information is:—How many amperes per square inch of area of contact on the commutator should be allowed for carbon brushes? So far as the writer's experience goes, 40 amperes per square inch is a good average, but some makers employ as low as

25 amperes per square inch of area of contact, whilst others allow as much as 60 amperes per square inch. A good deal depends on the size of the machine, the density being usually lower in a small machine because it may be convenient to use standard sizes of carbons. On the large generators for the Waterloo and City Railway, for example, giving 450 amperes at 550 volts, a quite sparkless collection is obtained by five carbon brushes, each with an area of contact on the commutator of 2 inches long by 1 wide. This gives

$$\frac{450}{5 \times 2 \times 1} = 45 \text{ amperes per square inch of contact.}$$

The ordinary 25 horse-power tramcar motor geared at 4·8 to 1 to a 33 inches tramway wheel, usually takes 15 amperes, but it may be suddenly called upon for five times that amount. The brush has an area of $2\frac{1}{2}$ inches by $\frac{1}{2}$ inch. In the more recent motors there are two carbons, each $1\frac{1}{4}$ inches by $\frac{1}{2}$ inch, or a total of $1\frac{1}{4}$ square inches, and we see, therefore, that the current density is usually somewhere about $\frac{15}{1{\cdot}25} = 12$ amperes per square inch, but it may rise on an emergency to 60 amperes per square inch. No doubt there is sparking at the high loads, but the results taken over a long period are undoubtedly much better than if metal brushes were to be employed for the purpose, even if they could be got to work well with the armatures running both ways.

It is interesting to compare the above with what is allowed for ordinary gauze brushes:—On a large 180-kilowatt dynamo giving 1,500 amperes at 350 revolutions per minute and with a commutator 12 inches in diameter, the current was collected by 12 brushes each 2 inches by $\frac{5}{16}$ inch on face. They were arranged in three sets of four in each set and a space of about $\frac{1}{8}$ inch was left between adjacent brushes.

The contact density works out at $\frac{1{,}500}{3 \times 4 \times 2 \times \frac{5}{16}} = 200$ amperes per square inch. Again, a multipolar machine with series armature has five brushes, each 2 inches by $\frac{3}{4}$ inch, (1 inch face) to collect 1,150 amperes, $\frac{1{,}150}{5 \times 2 \times 1} = 115$ amperes per square inch.

With reference to the actual conductivity of the carbon itself, this will vary with the quality. The Carré brushes, made from lampblack, naturally give the highest conductivity, but they are expensive, and a commoner quality made from petroleum coke, tar, and plumbago, in about the proportions of 70, 20, and 10 parts, is now most generally used. The plumbago acts as a kind of lubricant.

Good conducting carbon specially supplied for the purpose will easily carry 60 to 70 amperes per square inch of cross section without getting unduly hot, but, of course, the current density may be higher in small section carbons than in those of large section, on account of the proportion of the cooling surface to the area being so much greater in the first case. The curve given in fig. 1 shows how the temperature varies

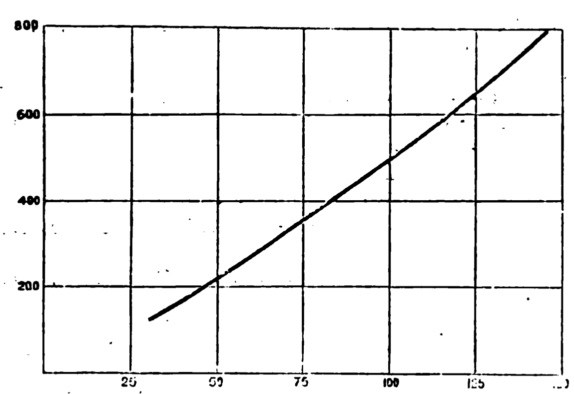


Fig. 1.—Curve showing the Heating of Carbon Brush pressed on to a Copper Plate.

with the current for a carbon block 1 inch square. In actual running it should be mentioned that the carbons are kept cool by the draught of air, and owing to the loose carbon dust the contact resistance is improved.

This matter of conductivity does not enter into the question so much with those brush-holders giving a metal support to the carbon to within, say, $\frac{1}{4}$ inch of the commutator; but where there is considerable overhang, as in the heavy Siemens type, conductivity becomes important. In fact, one objection to the use of carbon brushes on large dynamos, especially if they must pass a strict guarantee clause for efficiency, is that there may be an extra loss of 1 or 2 per cent. due to

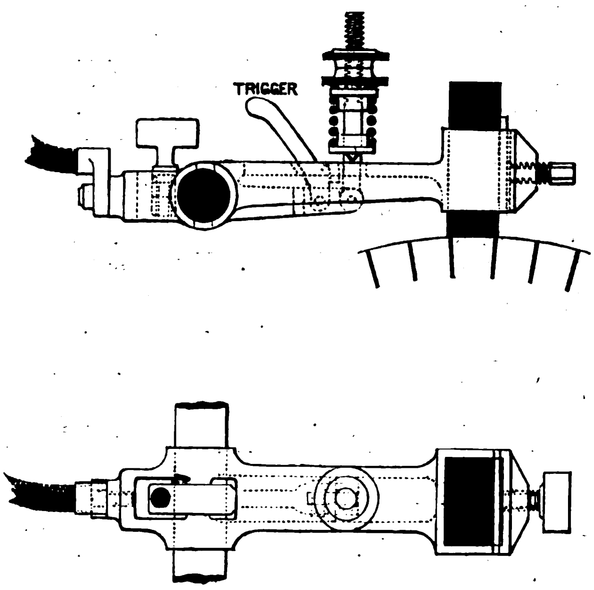

Fig. 2.—Plan.
Greenwood & Batley's Carbon Brush-Holder.

the brushes themselves. For example, the dynamos for the Leeds tramways were specified to have carbon brushes. The guarantee test for efficiency was made with metal brushes, with the result that Messrs. Greenwood & Batley, Limited, earned a good bonus, whereas if the carbon brushes had been used they would have only just scraped through. Fig. 2 shows the type of brush-holder (made of aluminium) in use on these machines, and it may be mentioned that the collection is as nearly perfect as possible, there isn't a sign of a spark however the load may vary.

One of the earliest recognitions of the fact that the use of carbon helped to stop sparking was made by Messrs. Crompton & Co., Limited, on some large machines which they supplied for aluminium reduction. The current taken off the commutator was considerable, and in order to reduce the

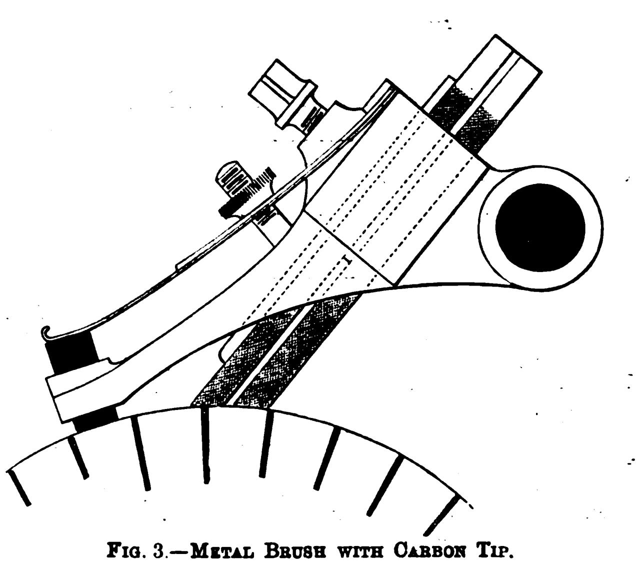

Fig. 3.—Metal Brush with Carbon Tip.

sparking as much as possible the ordinary metal brushes were fitted with carbon tips. Since then this method has been adopted on many other machines, especially where there were great variations in the load as well as large currents to deal with. A simple method of carrying the carbon block is shown in fig. 3. Arc lamp carbon may be used for the purpose, or the little dovetail blocks clamped to the end of a flat spring.

Before going on to describe the various types of brush-holders it would perhaps be as well to enquire into the reasons why the mere substitution of a block of carbon instead of a metal brush improves the commutation. In order to do this properly, it will be necessary to consider for a moment the various causes of sparking. For, although armature reaction is the fundamental cause, there are other reasons, such as the impedance of the coil under short circuit, the time interval, and the thickness of the brush, which effect the question to a greater or less degree.

In the single core continuous current transformer the armature coils connected up to one commutator are paralleled by another set connected to the other commutator, and thus the magnetic effect of one is neutralised by that of the other. In other words, there is very little armature reaction and practically no lead to the brushes. Yet those who have worked these machines know that sparking is not necessarily eliminated.*

There is Messrs. Mavor and Coulson's combination of an auxiliary pole and the Sayer's reversing coils, also Messrs. P. R. Jackson's development of the latter. The partial reduction of the cross magnetising effect by an exaggerated chord winding as described in Mr. Mordey's paper on "Dynamos," and the thorough lamination of the poles (at right angles to the lamination of the armature core), as suggested by the writer, see *Proceedings of Institution of Electrical Engineers*, Vol. xxvi., page 598. Partial lamination of the field poles and shaping the poles away at the horns which tend to be strengthened by the cross magnetism, is, perhaps, the simplest method of reducing the lead.

All these arrangements are good as far as they go, but there are other causes of sparking which require to be attacked from the entirely external standpoint of the brushes themselves.

Any device which makes good commutation possible with a considerable lead on light loads, means that the machine can be successfully operated with little or no change of lead under varying loads.

Now, experiment has shown that this may be effected by placing an extra resistance in the circuit of the short-circuited coil. With a metal brush this can be effected by making it in several sections with a high resistance coil of small area (platinoid wire) between each. The heat waste and sparking caused by the difference of potential between adjacent segments respectively in contact between the advance and hinder sections of the brush is thus prevented.

(*To be continued.*)

* Dynamos have been designed (Prof. Ryan) on the lines of a continuous current transformer with the second or neutralising coils wound in slots in the pole faces. As these slots were filled with copper they added considerably to the reluctance of the magnetic circuit, and it was therefore proposed to make the conductors of slabs of wrought-iron insulated from, but bolted to, the poles. The writer went into this with Mr. Mordey in 1893, but came to the conclusion that the cost of machining, insulating, and connecting up at the ends was too stiff a price to pay for the somewhat doubtful advantage of eliminating the lead of the brushes.

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. THOMPSON & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

8,019. "Improvements in or relating to alternating motors." A. J. BOULT. (O. Patin.) Dated April 4th.

8,024. "Improvements in means or apparatus for electro-plating." H. V. R. READ and N. G. THOMPSON. Dated April 4th.

8,037. "Improvements in the manufacture of the peroxide elements of secondary batteries." D. G. FITZ-GERALD. Dated April 4th.

8,043. "Improvements in sockets or holders for incandescent electric lamps." J. W. MACKENZIE. (Allegmeine Electricitats-Gesellschaft, Germany.) Dated April 4th.

8,054. "Improved means for fixing or fitting incandescent electric lamps into lanterns." J. MOORES and H. O. FARRELL. Dated April 5th.

8,059. "Improvements in apparatus for lighting miners' safety lamps by electricity." B. D. WILLIAMS. Dated April 5th.

8,070. "Improvements in electric trolly wire section insulators." W. WOOD. Dated April 5th.

8,085. "Incandescent electric light decorations." A. A. POLLOCK. Dated April 5th. (*Complete.*)

8,097. "A medical electric generator or hot-air bath for the application of heat to the human body." A. E. GREVILLE. Dated April 5th. (*Complete.*)

8,104. "Improvements in electrical measuring instruments." F. M. BENNIT. Dated April 5th.

8,140. "Improvements in switches for electric circuits." G. WRIGHT. Dated April 5th. (Date applied for under Patents, &c., Act, 1883, Section 103, September 18th, 1897, being date of application in United States.)

8,142. "Improvements in systems of electrical distribution." B. G LAMME. Dated April 5th. (Date applied for under Patents, &c., Act, 1883, Section 103, September 18th, 1897, being date of application in United States.)

8,149. "Improvements in electric welding machines." C. NIELSON. Dated April 5th.

8,179. "Improvements in and connected with means for electrically lighting railway carriages." E. DICK. Dated April 6th.

8,192. "Improvements in electrical connections, switches, and terminals." R. F. HALL. Dated April 6th.

8,202. "Apparatus for quickly and tightly closing, and quickly opening portable electric batteries." S. F. WALKER. Dated April 6th.

8,222. "Improvements in clutches and brakes for arc electric lamps." G. BYNG and A. E. ANGOLD. Dated April 6th.

8,233. "Improvements relating to electric tram and like cars." J. T. HIMMEGER and J. CROWLEY. Dated April 6th.

8,262. "An improved controlling device for electric motor vehicles and the like." G. H. RAYNER. (H. Leitner, France.) Dated April 6th.

8,273. "Improvements in and connected with electric bells." H. OPPENHEIMER. Dated April 7th.

8,274. "Improvements in and connected with electric bells." H. OPPENHEIMER. Dated April 7th.

8,275. "Improvements in and connected with annunciator movements." H. OPPENHEIMER. (Actien-Gesellschaft Mix & Genest, Germany.) Dated April 7th.

8 276. "Improvements in and connected with primary batteries." H. OPPENHEIMER. Dated April 7th.

8,277. "Improvements in and connected with keys or switches for multiple switchboards." H. OPPENHEIMER. (Actien-Gesellschaft Mix & Genest, Germany). Dated April 7th.

8,278. "Improved fuse box for electric light cables requiring resin, oil, or other compounds as an insulating material at terminal joints, &c." D. S. STRANG. Dated April 7th.

8,298. "Electro-photo-telegraph." A. BEIN and J. BREUER. Dated April 7th.

8,301. "Improvements in the construction of Morse's registering telegraphic instruments." E. DUCRETET. Dated April 7th. (*Complete.*)

8 314. "Improved electric pile." G. ROSSET and J. ROSSET. Dated April 7th.

8,319. "Improvements in electrodes, and in the method employed for producing them." K. KREBS. Dated April 7th.

8,328. "Improvements in or relating to electric arc lamps." A. ROSS. Dated April 7th.

8,348. "Improvements in electrical measuring and indicating instruments." A. C. HEAP. Dated April 7th.

8,371. "Improvements in electro-magnets." M. BOUCHET. Dated April 7th.

8,374. "Improvements in arc lamps." G. C. FRICKER. Dated April 7th.

8,391. "Improvements in high-tension transformers and induction coils for Röntgen ray work, and for other purposes." A. L. DAVIS. Dated April 9th.

8,393. "Improvements in electric arc lamps." H. V. JAMES. Dated April 9th.

8,398. "Improvements in electric motors." P. S. SWAN. Dated April 9th.

8,441. "Electric recording system." C. L. JAEGER. Dated April 9th. (*Complete.*)

8,442. "Improvements in electric meters, cores, and circuit controllers." W. D. MARKS. Dated April 9th. (Date applied for under Patents, &c., Act 1883, Sec. 103, September 10th, 1897, being date of application in United States) (*Complete.*)

8,477. "Improved electric accumulators." B. A. BOUVIER and G L. AUGIERAS. Dated April 9th.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

THE SHIFTING SITE OF NATIONAL INDUSTRIAL SUPREMACY.

THE aspects of national industrial supremacy in the iron trade have been ably dealt with of late in the *Engineering Magazine* by Mr. Jeans, who now again writes under the above title, and argues the question of cheap and dear labour. Mr. Jeans has left over this article until he could, in some measure, estimate the result of the strike, and he is optimistic on the prospect. He endorses our already expressed opinion, that if the result of the strike be to put a stop to the bad and dishonest conditions which have been prevailing, there is much brighter prospect for British industry. Great Britain, says Mr. Jeans, has suffered more loss of prestige to her industrial character from the bad side of trades unionism than from any other cause. Mr. Jeans has otherwise a high estimate of British labour—its skill, doggedness and capacity to produce good work, and no Englishman need be afraid of comparison with Continental products.

A factor in industrial supremacy is a large home demand. This it is has built up trade for the United States. Home demand brings works into existence, and these expand, and finally are able to produce for outside. The absence of home trade has kept unprogressive countries in a backward condition as regards metallurgy. For example, take Russia, with a population in 1880 of 100 millions, and a pig-iron manufacture of only 465,000 tons, of finished iron 292,000, and of steel 307,000, whereas undeveloped America produced four million tons of pig and three million of finished, or partly finished, products. America was progressive, and has now obtained the first place in iron production, though still second in production per head of population, and very low down in production per area. Mr. Jeans is of opinion, and he claims that his opinion is based on experience, that no country possesses such resources as to give it a supremacy in so widely diffused an industry as iron and steel making for a very long time. The ore and coal deposits of New South Wales are so great as to afford the expectation of production as cheaply as in any other country. Then there are the resources of British India, of China, Siberia, Japan. In India especially the coal and iron resources are great and are widely spread. In Spain there are good prospects, and the newer Spanish ironworks are well equipped, and there are the conditions in embryo that would enable pig to be made as low as 28s. per ton—practically the cheapest price in Europe. Russia is now progressing, and the demand in Siberia may become great now that railway facilities are provided. The total iron production of the world, which was not five million tons in 1850, grew to 12 million tons in 1870, and then in 1880 to 18, and now to 32 millions. It will be 46 millions in 1916, and 60 millions in the lifetime of most young engineers now living, if the present rate of growth be continued.

Where can anyone at present see the source of the extra 50 million tons of ore to provide for the demand in 36 years hence? Great Britain certainly cannot hope to do more than put out her present annual 15 millions of tons. Germany is in no better case. France has stuck for many years at 3½ millions, despite the large deposits of the Meurthe-et-Moselle district. That country, apparently, must be first which can put out the biggest weight of ore. But it is not materials alone which tell. Much depends on the character of the people. A skilled and industrious population is necessary, such as found in Great Britain or the United States, and rarely in semi-civilised countries like Russia, or in fallen-back nations like Spain. The unquestioned efficiency of the British workman—when he chooses—may in the future be found allied with the willingness of the American, and show itself in the running of plant for all it is worth. If so, the change will greatly modify the present conditions. In the best American works it may be assumed there is now little or no reserve of force. In Great Britain we have a reserve of *30 to 60 per cent.*—the italics are ours.

If Mr. Jeans be right, and he only voices our own ideas, the geographical and climatic advantages of Great Britain must tell powerfully in the future as in the past. Already a few of our leading works, Barrow, Dowlais, Bolckow, Vaughan & Co., now compare favourably with any in America as to costs, and the old country has plenty of "kick" still left, and one of the surprises of the future may be a resurrection of British supremacy on a scale quite undreamed of. John Bull is so very pessimistic—he does not magnify his powers or achievements, and when it is considered that Great Britain has everything but ores, and they can be so readily and cheaply imported, it is unlikely that she will suffer eclipse.

Lately, conditions have not been fair. Germany and America have kept up home prices by pools and syndicates, and dumped surplus production into neutral markets at prices only possible under the pooling conditions at home. In fact, the German and American public have been really presenting iron to foreigners in the way France and Germany present sugar.

The near future, probably everywhere, will bring the legislative cost of production a little higher. Already this is 1s. 3d. to 1s. 6d. per ton in England, and it is considerable in Germany. It is likely to increase in America as greater care of life increases. The United States also are not likely to be so free of war burdens, or Europe maybe will drop some of her crushing load by federation. With a quarrelsome America the Continent of Europe might find it necessary to federate for its existence, and America has already evinced strong desires to go outside her own territory and drop the Munroe doctrine of non-meddlesomeness.

The present Spanish imbroglio seems likely to result in heavy war expenditure in America, demanding taxes which will even up costs of production and place American industry under charges more approaching to those borne by others. Such would seem to be the outcome of the note struck by Mr. Jeans in his article, for already he states few of the leading American works have been of late making large profits. One notable exception remains, which we take to be the Carnegie Company, and this has made handsome profits on account of efficiency of administration and singleness of purpose rarely equalled in manufacturing annals.

The Belleville Boiler at Sea.

At the time of the much lauded trials of H.M.S. *Powerful* we ventured to doubt the propriety of such an expensive and serious experiment. Hints as to the fearsome coal consumption of this fine ship do not tend to re-assure us. A paper just presented to the Institution of Engineers and Shipbuilders of Scotland by a Russian engineer detailing his experience on board the ss. *Kherson* adds further testimony to the inadequacy of the circulation in Belleville boilers. In the *Kherson* there are 24 boilers placed back to back athwartships—this position, to our mind, being specially suited to put a check on proper circulation. In each boiler are eight elements of 20 4½-inch tubes each, the lowest tubes ⅜-inch, the two next $\frac{5}{16}$, and the top two rows ¼ thick. When first tried the port side boilers did not work so well as those on the starboard, the bottom box joints to feed collectors leaking. When the trial was over it was found the ship listed 10½° to the starboard. At a second mooring trial the list was 5° and reversed, and the same faults were repeated, but also on the opposite side, and the faults were less pronounced, owing, perhaps, to less list and a shorter run. The faults developed consisted of the bending down of the tubes from 1 inch to 1½ inches. Throughout the voyage faults always occurred on the side opposite to that towards which the ship listed, and a point of peculiar interest was that previously bent tubes tended to become straight, and some even bent upwards, as, indeed, is the normal tendency of the lower tubes of Belleville boilers. Mr. Gretchin attributes, we think rightly, the trouble to the list causing the odd rows of tubes to become horizontal if the list is 2½°, and to incline the wrong way when the list exceeds this amount. Mr. Gretchin's experience points to the need of very skilful firing of fires 3 to 4 inches thick, and he details the system of routine working, continuous repairs at sea and in port, and, altogether, his paper is lively reading for anyone who knows even a little of life at sea, and can picture the succession of bent tubes, leaks, split welds, the rattling of non-return valves as the ship rolled as if to prove the need of these in the mud boxes. Nothing that has yet come to light concerning the Belleville boiler has tended to re-assure us as to its suitability for steam raising in defence of the empire.

Permanent Indicator Rigs.—The *Street Railway Review* describes a convenient permanent indicator rigging which gives a thoroughly perfect movement. It consists of a shaft parallel with the piston rod, and supported in bearings bolted to the underside of the upper guide. The shaft is sufficiently to one side to clear the crosshead, yet close to the guide frame, to allow free access to the gland, &c. To the shaft is fixed a brass strip, so curved as to form a portion of a high pitched helix. This is engaged by a fork belted to the crosshead. The fork carries rollers. A movement of the crosshead of 60 inches gives the shaft, by engagement of the fork and helix, a rotation of something less than 60°. Motion is carried by means of cranks and connecting rod from the shaft to a second shaft, carried in brackets on the side of the cylinder. Small cord wheels on this second shaft carry the cords to the paper barrel. We think we have somewhere seen a similar arrangement carried out by means of a slightly twisted square bar, such as is used in the valve gear of a fire engine. Any device to be successful at high speeds needs to provide for the shortest possible cords, and should be of great rigidity compared with its weight, or at least its moment.

"FREE" AND "EASY" PAYMENT SYSTEMS OF HOUSE WIRING.

By V. ZINGLER, A.I.E.E.

(*Concluded from page* 533.)

Now there is no doubt that Mr. Rider has only put forward this ingenious scheme with the idea of enabling the Corporation to increase their electricity supply, and so to benefit the public not only by the general distribution at cheaper rates of a healthy illuminant, but also by saving their pockets from the heavy initial outlay otherwise involved by the adoption of the electric light. It is questionable, however, whether the scheme will commend itself in its financial aspects to students of scientific economy.

It is a curious medley of municipal socialism and reactionary individualism. Much as we all desire to see the general application of electricity either by private or by municipal enterprise, it is doubtful whether such a scheme as this should not be considered as dangerous — alike from the nature of the thing and the abuses it may bring forth. For what does it amount to? It is a scheme by which a municipality—a public body—takes upon itself the compound function of money lending and the support of one-man businesses. And what can it lead to? Nothing but bribery and corruption. What is to prevent councillors from having interests in the wiring firms thus supported, or from being themselves in receipt of "relief" on account of such work done for them, with the accompanying possibilities of fraud, commission, &c., which it is better not to enter into?

Consider the litigation which the Corporations will get into over clause (*a*)! Suppose that the satisfaction of the consumer does not correspond with that of the borough electrical engineer, and that the consumer refuses to pay anything further. Also, to whom will the installation belong during the period from completion to payment on the part of the Corporation? Who is to adjudicate upon extras, such a favourite item in a wiring contractor's bill? No doubt these are only minor points, and could be duly allowed for in any agreement; but the broad principle of the thing remains the same. We have not got so far in our social conditions that the community should be called upon to pay the debts of one of its items, or to suffer loss through the defaulting of a member.

It may be argued that there is no difference between this scheme and the Corporation wiring the man's house themselves, as in any case they spend the ratepayers' money. But there is a difference between paying a man's debts in money and in kind; if the consumer absconds or declares himself bankrupt, the money is as good as lost, as it does not follow that another consumer will always take the same house at once, or, having done so, will use the electric light; and he could not be compelled to do so, as the agreement would only be between the original tenant and the Corporation; whereas, if the Corporation wired the house themselves, they could come to terms with the landlord, so that their ultimate payment, with interest, would be assured.

These remarks are merely looking at the question from the standpoint of the community, and, apart from the fact that altruism does not flourish sufficiently among us that we should have a rabid desire to advance each other money *ad lib.* (for where electric light trades have this advantage others will also require it), it is questionable whether such powers could be exercised by a corporation without the permission of Parliament, or whether Parliament would give that permission.

Mr. Rider summarises the advantages of his scheme from the standpoints of Corporation, consumer and contractor, as follows:—

To the Corporation the advantages would be—

(*a*) The accession of a large number of consumers who would otherwise not be able to afford to adopt the electric light.

(*b*) The excellent control the Corporation would be able to exercise over the wiring of the premises, and the consequent raising of the standard of work.

To the consumer the advantages would be—

(*c*) The adoption of electricity as an illuminant without any heavy initial outlay.

(*d*) No extra price for current, as in the free wiring scheme.

(*e*) The cessation of all payments for wiring after a certain time, when the work would become the property of the consumer.

(*f*) The guarantee of first-class work, under the direct control of the Corporation.

To the contractor the advantages would be—

(*g*) A large increase of work in wiring premises.

(*h*) The certainty of payment on the satisfactory completion of the work.

Let us just consider these:—

(*a*) is no doubt the best advantage that the scheme has to offer. It may, however, be asked, are there many consumers who, if they could not afford to pay £100 down, would readily assent to a quarterly tax of over £12 for 21 months for the sole object of afterwards owning certain fixtures in a house which does not belong to them?

(*b*) If the control were to be greater than that adopted now, the Corporation would have to engage a larger staff. Besides, the controller would always be subject to being squared, or to getting on too friendly relations with contractors, as often happens now.

(*c*) The same remarks apply to this as to (*a*).

(*d*) This will be dealt with afterwards.

(*e*) Dealt with under (*a*).

(*f*) Dealt with under (*b*).

(*g*) Excellent for the wiring companies, subject to the scheme becoming popular with the public.

(*h*) Also good for the contractor, if no legal difficulties such as have been suggested before intervene.

We may now consider the scheme of the Free Wiring Company in conjunction with that of Mr. Rider's, in the relative positions of their advantages to the consumer, *i.e.*, to his pocket; for, after all, this is what the average man considers, and rightly enough, before all. And this comes in special relation to (*d*).

The consumers catered for under either of these schemes are those whose incomes are from £500 downwards, and who could not afford to pay £100 (or a proportional amount as their income decreases) in cash down for electric light. To these people—and they form the great majority of possible consumers—the question of the general application of the electric light and the consequent reduction in the charge per unit or in the parish rates, is as nothing compared with the sudden expenditure of one-fifth of their income. No doubt they would be glad to have the rates reduced, but not by the offer of such a sacrifice. What such a man has to consider then, under these alternative schemes, is this: Assume, for convenience, that he has 100 lights to be wired for at £1 each, consuming 18 units each per annum. Under Mr. Rider's scheme he will pay £100 + 5 per cent. = £105, in eight quarterly instalments of £13 2s. 6d. each, spread over 21 months. As Mr. Rider points out, this is equivalent to getting credit for the full amount of £105 for $10\frac{1}{2}$ months, or at the rate of about $5\frac{3}{4}$ per cent. per annum. He will thus not only lose his interest on the £100 he spends, but he has to pay an additional 5 per cent. for the loan. His consumption per quarter will be, at 6d. per unit,

$$\frac{18 \times 100}{4} \times 6 = £11\ 5s.$$

Of course he may not burn anything like this, but the figures may be taken for purposes of comparison.

Now, if he takes up the scheme of the Free Wiring Company, he will have to add one-sixth to this latter sum, assuming that the charge is 1d. extra per unit consumed.

This will make his quarterly bill for current £13 2s. 6d., or, curiously enough, just equal to what he would be paying off quarterly under Mr. Rider's scheme for nearly two years, to obtain certain fixtures as his own property which are of no more value to him than the water-pipes in his house.

The sum he pays under the Free Wiring Company's scheme per quarter is £1 17s. 6d., or at the rate of $7\frac{1}{2}$ per cent. per annum.

To sum up, under the one scheme he will be paying £24 7s. 6d. per quarter for two years, and £11 5s. per quarter afterwards, and own certain fixtures in, probably, another man's house, which would not realise anything; to this would be added legal proceedings if he got into arrears. On the other hand, he would pay £13 2s. 6d. per quarter as long as he liked, with no disabilities attached except the cutting off of the light if he failed to pay.

It is for Corporations anxious to take up a scheme of this sort to consider human nature first, and to ask themselves which scheme they would prefer if they were in the position of this man.

As the writer is not aware whether Mr. Rider's scheme has been adopted at Plymouth or elsewhere, no figures as to its operation can be given; but there is no doubt that the scheme of the Free Wiring Company is being taken up by many supply companies and corporations. It must be evident that it is of great assistance to the supply companies and corporations for increasing their load; in fact, this is so to such an extent that some of them have decided to charge the consumer nothing for the hire of the wires and fittings—presumably instead of reducing the cost of the unit as the load increases. If the thousands of small houses in the suburbs which are without the electric light are considered, the possibilities of any scheme of this sort are immense; and that it is not only the small consumers who sometimes take advantage of it is shown by the fact that in one district worked on this scheme and started contemporaneously with the supply authority, considerably over one half of the consumers have been "free wired," and these used over 80 per cent. of the total current supplied.

Under this system the consumer has the option after five years of purchasing the installation on payment of the original cost plus 20 per cent., and less $1\frac{1}{2}$ per cent. per annum from the date of installation for depreciation. It is not probable, however, that many consumers would avail themselves of this. Certainly, 20 per cent. seems a large profit, and $1\frac{1}{2}$ per cent. a small depreciation after five years, and after paying $7\frac{1}{2}$ per cent. interest.

But the system has this advantage—that the landlord does not in any way become responsible for the defaulting of any tenant, as the wires and fittings remain the property of the company, who can remove them if payment is not forthcoming. They are, however, bound to make good any damage caused by this removal.

In conclusion, it may be pointed out that when the gas companies saw their lighting business threatened by the introduction of the electric light, they applied themselves to encouraging gas cooking and heating by letting out stoves, &c., on hire for a very moderate sum. That there is a demand for these is shown by the fact that the gas companies' profits have not decreased, despite the great progress made by the electric light. As borough engineers and others are always grumbling at the great valley in their load curve, because most of their machines have to stand idle during the daytime, it is curious that no effort is made, either by the supply authorities, or some company, to let out on hire electrical cooking and heating apparatus, not to speak of motors. Owing to their cleanliness and economy in heat, there would no doubt be a ready demand for them, and the item of wiring would be extremely small.

THE MECHANISM OF ELECTRICAL CONDUCTION.*

We print in another column of the present issue (page 596) the latter part of an interesting and suggestive paper recently read by Mr. Reginald A. Fessenden before the American Institute of Electrical Engineers. The paper consists of two parts; the first, highly speculative, discusses the mode by which electricity is conveyed through solids, liquids, and gases, and supports the general view that all conduction is essentially convective, if the circumstances of the constitution of materials, solid or fluid, which determine whether they are conductors or insulators, are considered. We confess we do not follow throughout the reasoning of this part of the paper, but some account of its argument may induce our readers to refer, perhaps more intelligently than ourselves, to the original. The second part of the paper deals with the properties of insulating substances used in engineering practice, and appears to us of so much practical interest that we print it *in extenso*. That many of Mr. Fessenden's views admit of much controversy does not detract from their interest.

The author begins by drawing a careful distinction between the two qualities necessary to an insulator, viz., non-conductivity and dielectric strength; to both which qualities, he complains, the term resistance has been indiscriminately applied. He points out that water is, so far as the latter quality is concerned, at least as good an insulator as India-rubber, and, in another section of the paper, that only its enormous solvent power prevents its being a good non-conductor.

The paper then considers the mechanism of conduction in four sections: conduction by convection, conduction in solids, fluids, and gases.

Liquid insulators, even very perfect non-conductors, will conduct by convection, and this may cause serious leakage in high potential distribution. Convection is not recognised as occurring in solids, but is well marked in gases, vapours, and fluids. The mechanism of convection is the repulsion from a charged body of other bodies which have been in contact with it, which move away carrying with them part of its charge. Now, small bodies charged from another, comparatively large and smooth, are not repelled from but attracted to it; and though it is stated that the relation between the size of the particle, the voltage, and the radius of the charged conductor, when the particle after touching the conductor is neither attracted nor repelled, can be obtained by the method of images, no numerical results are given, for which omission the author apologises. Leakage between conductors in a liquid insulator, so far as it is due to convection, is caused by a motion of a portion of the oil as a whole, and not of its individual particles. Leakage by convection in a liquid insulator can be prevented in three ways:

"1. By using oil of great viscosity, in which case, however, we lose the chief advantage of oil insulation, *i.e.*, its ability to re-insulate quickly after a discharge."

"2. By putting pure dry cellulose in some form or other between the charged surfaces loosely, so that the oil can filter through it easily and any air escape readily, but sufficiently close to prevent any rapid flow. Pure cellulose has the great advantage that when well boiled in the oil it has approximately the same specific conductive capacity as the oil. No varnish or shellac should be used in the oil for reasons given later."

"3. By dissolving a solid, non-dissociating substance in the oil in such excess that it crystallises out at ordinary temperatures and forms with the oil a soft gelatinous mass, not fluid, but yet capable of allowing the oil to ooze through its substance. This has many of the disadvantages of 1, but it has one advantage, in that the substance chosen may be one, like paraffin, having a large specific heat of liquefaction, and consequently an overload will not raise the temperature of the oil above a fixed point till the paraffin is all melted."

No rapid movement of the liquid can occur in any of these arrangements, and the convection currents must be very small. It is further pointed out that the well known discharging effect of points is due not only to the great density of the charge at places of large curvature, but largely to the fact that very small particles are repelled from points, and can move rapidly away, carrying their charges, while they would not be repelled at all from rounded knobs or surfaces of small curvature.

In relation to the conductivity of solids, the author refers to a relation between the properties of a metal which he discovered and announced in 1892.

The conductivity of a pure metal is proportional to

$$\sqrt{\frac{\text{elasticity}}{\text{density}}} \div \text{valency}:$$

or in other words, the product of the conductivity of a pure metal and its valency is proportional to the speed at which it conducts sound. In evidence of this law figures are given of 10 other metals referred to silver, but they closely satisfy the formula in only three cases, viz., gold, aluminium, and cadmium; the values in those cases being as follows:—

* "Insulation and Conduction." A paper read by Mr. Reginald A. Fessenden before the American Institute of Electrical Engineers, New York, March 23rd, 1898.

Metal.	Atom. Vol.	Atom. Wt.	Valency.	R. calculated.	R. observed.
Silver ...	10·2	108	1	100	100
Gold ...	10·2	197	1	135	137
Aluminium	10·5	27	3	152	159
Cadmium	13	112·2	4	456	450

In other cases there are discrepancies from 13 to 83 per cent. The worst case is that of iron, in which the calculated resistivity is 480, and the observed 646. Iron is taken to be octovalent, and if tetravalent the figure would be only 240, but Mr. Fessenden observes that "the magnetic metals, as iron and platinum, are very difficult to obtain pure. Their true resistance is, therefore, at present doubtful." The values attributed to the valencies of the metals seem somewhat arbitrary, and upon this point the author, referring to a diagram, in which, by the way, cadmium is assigned a valency 2, writes: "But there is no very definite rule. Among the univalent elements some unite with bivalent atoms, as does copper, and in general all that can be said is, that a certain valency holds generally and not in general. Consequently when we find that by taking a group of metals having very closely the same value of Young's modulus, as, for instance, gold, silver, and aluminium, their conductivities are, within the limits of errors of observation, proportional to the velocity of sound ÷ valency: and that in any of the group of metals having the same valency, the conductivity is directly proportional to the velocity of sound, within experimental errors, we are to a certain extent justified in making a choice of valencies when this is needed."

If this law be established it points clearly to convection as the mode of conduction in solids. To quote again:—"This formula throws a certain light on the nature of conductivity in solids, and why some solids are insulators. For the formula $\sqrt{\frac{\text{elasticity}}{\text{density}}}$ is the same as that for velocity of sound in a body. Now, in the convective discharge, the electricity was handed on with the same velocity as that with which the particles moved. In fluids, as we shall see, the electricity is handed on with the velocity with which the ions move. In both cases the electricity travels along on the particles of matter." A long quotation from Prof. Lodge follows indicating that this idea was well founded in his mind 10 years ago, and it is suggested that had he known of a formula subsequently discovered by Mr. Fessenden, and published in the *Electrical World* (New York), August 22nd, 1891, his views would have been much strengthened.

"The formula refered to is:

$$\text{Young's modulus} = \frac{78 \times 10^{12}}{(\text{atom. vol.})^2}$$

"Hence it is possible to predetermine the velocity of sound in wires by the formula:

$$\text{Velocity in cms. per sec.} = \frac{883 \times 10^4}{\text{atom. vol.} \times \sqrt{\text{density}}},$$

"and the electric resistivity is given roughly by:

$$\text{Resistivity} = 45 \times 10^{-9} \times \text{atom. vol.} \times \sqrt{\text{density}} \times \text{valency}.$$

"This formula possesses a general interest, inasmuch as it would seem that while the strain in the dielectric is propagated with the velocity of light, *i.e.*, $\sqrt{\kappa\,\mu}$, the actual electricity in the wire were handed on with the velocity of sound, and is proportional to $\sqrt{\frac{\kappa}{\mu}}$."

Mr. Fessenden thus arrives at the general conclusion that metals probably conduct by handing on charges to one another as they meet or collide in the course of their natural vibrations, and that the rate at which charges can be passed through their substance, *i.e.*, their conductivity, is proportional to the number of collisions in a given time, and inversely to the valency. The action of a high valency in reducing the conductivity of the metal is not very clear, but we understand that Mr. Fessenden looks on a high valency as involving small freedom of motion among the molecules, and so fewer collisions. An ingenious mechanical arrangement of balls carried on stretched strings is described, which would behave analogously to the author's conception of a conductor.

We find it difficult to follow the writer in his discussion of the molecular qualities necessary to produce solid dielectrics. He points out from a table of the elements constructed on Mendeléeff's principle that, as we proceed from the highly conducting metals used in commerce towards those of lower rows and higher valencies the substances get more crystalline, highly polymerised, and capable of existing in allotropic forms, and adds a number of general considerations on the effect of highly complex structure on the transmission of vibration. He concludes that for solid insulators we require "substances which are strongly linked together, of great density, and of small modulus of elasticity." In considering the conductivity of liquids the results arrived at by a number of well-known physicists are briefly stated, the condition that determines whether a given solution is an electrolyte or an insulator being the attraction of the molecules of the solvent for the ions of the solute. If this attraction is sufficiently great to overcome the cohesion of the molecule of the solute, and break it up into ions, the liquid is an electrolyte, but if not it remains an insulator. To quote Mr. Fessenden:—

"The conductivity of a solution is thus dependent upon the following:

"1. How powerful the attraction of the molecules of the solvent is for the ions of the solute, for on this depends how much of the solute is disassociated, *i.e.*, how many ions are set free to carry the current.

"2. How fast the ions move.

"3. What the valency of the ions is.

"In designing insulations the first is the important point, for from it we see that two good insulators mixed do not necessarily make a good insulator. A solid may dissolve in one substance and be an insulator in solution, but in another solvent may conduct quite well.

"This is what makes the chief difference between fluid insulators, for practically all the fluids which are not simple elements, like mercury, have very high ohmic resistance, and all have practically about the same dielectric strength. The ohmic resistance of pure water is, according to Kohlrausch and Heydweiller, about 1 megohm per cubic centimetre, consequently on account of its non-inflammability and great specific heat, its great heat of vaporisation and low boiling point, it would be a very valuable insulator for some types of apparatus were it not for the fact that it dissolves almost everything in slight proportions and splits them up into ions. Varnished paper will dissolve in some high resistance oils, forming a conducting solution."

In treating conductivity in gases, Mr. Fessenden adds little to what he has already said. Looking on all conduction as essentially convective, calling it electrolytic when the charges are conveyed by disassociated ions, he has no doubt that conduction by gas is usually electrolytic, but thinks it may take place by convection, using the word in the usual sense, in the arc and in the vacuum tube. "As regards the electrolytic discharge, this can only take place when the gas is disassociated by heat or by a strong slope of potential."

Our copy of this paper is an advance proof kindly sent to us from America.

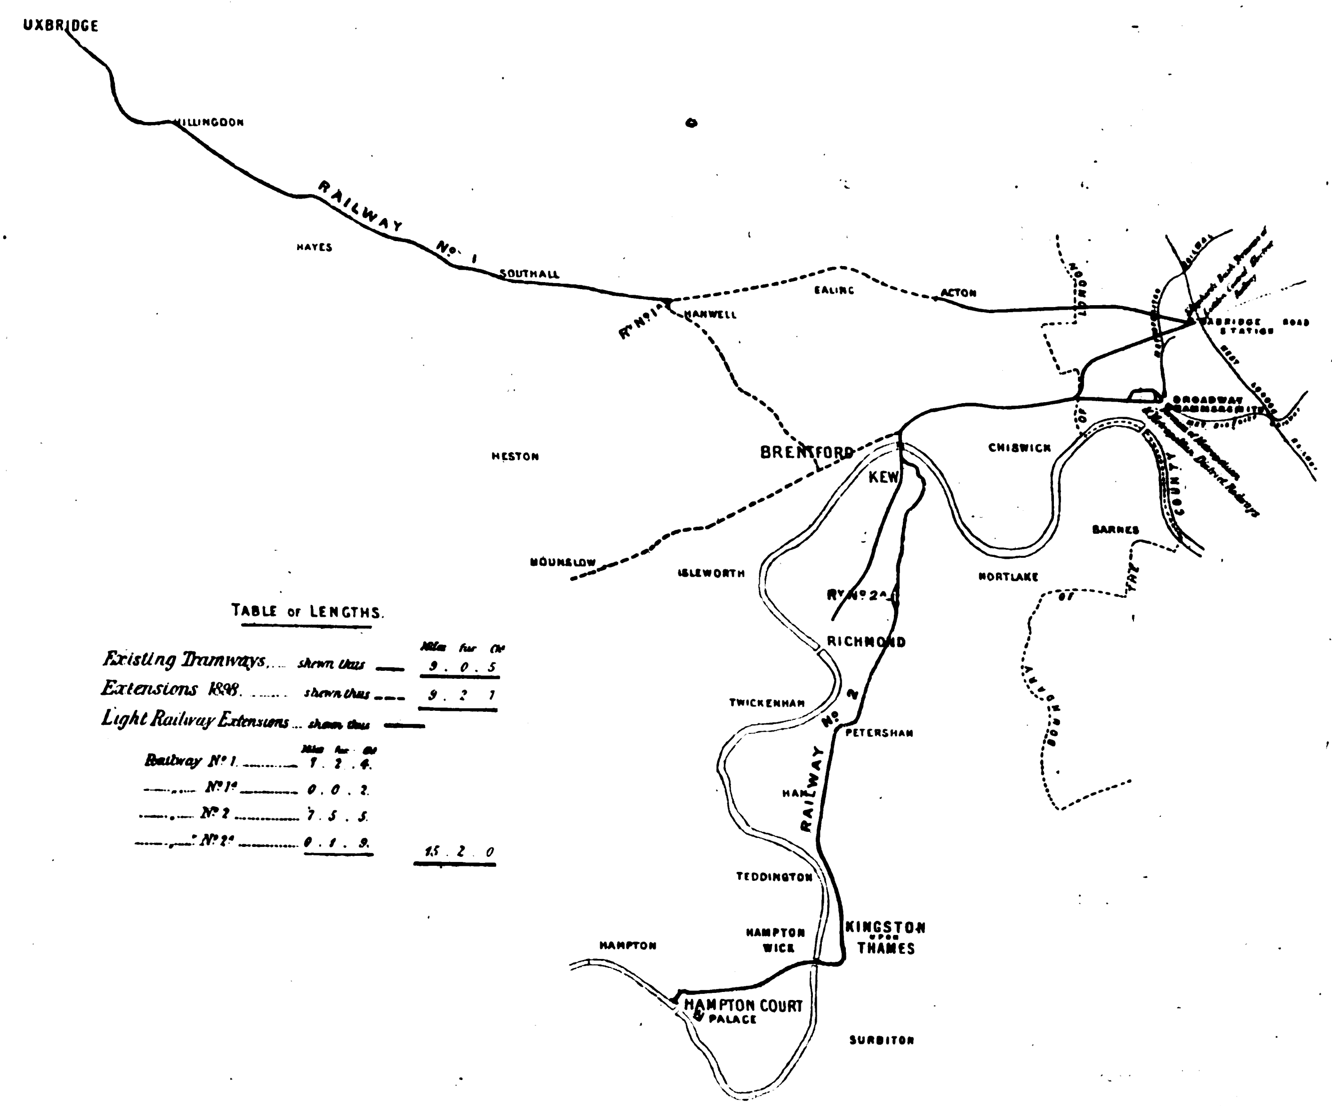
A GREAT SCHEME OF ELECTRIC TRAMWAYS.

The most ambitious scheme of electric tramways ever promulgated in this country is one that will provide a quick service of electric cars between Uxbridge Road Station and Uxbridge on the one hand, and Hammersmith Broadway and Hampton Court on the other hand. The proposed routes are clearly shown in the annexed map, from which it will be seen that the scheme embraces the equipment of existing horse lines with electrical plant and extensions into new districts. The present tramways are owned by the London United Tramways Company, of which Mr. Clifton Robinson is the engineer and managing director. It is perhaps hardly necessary to say that Mr. Robinson has been, and is, associated with most of the electric tramways that have been laid down in this country, so he may be said to be well fitted to fight the cause of electric tramways in West London. For there has been a battle royal waged round electric tramways in the two parishes of Ealing and Chiswick; indeed, so high did local feeling run that the elections of the Chiswick and Ealing District Councils, which took place some two or three weeks ago, were fought on the question of permitting or preventing the admission of electric traction into the districts. The result of the elections was a signal victory for those candidates who sought the suffrages of the electors on the grounds that it was desirable to permit the tramways company to introduce electrical working on to that part of the system which passed through the district. The result of this appeal to the ratepayers is distinctively interesting, because it reveals in the clearest possible manner the attitude of the public on the subject of electric tramways, despite the insidious attacks and unfair arguments of its opponents.

The existing lines of the London United Tramways Company are nearly nine miles in length, and the system com-

districts which appear to offer greater prospects for the successful working of electric tramways than the neighbourhood west of Hammersmith. The thoroughfares are wide and the population is exceedingly dense (in numbers). A well-equipped tramway system would prove a real blessing to the inhabitants and would, moreover, open up the country beyond Ealing and Hanwell which would be advantageous to property owners and residents alike. We have never seen a better equipped horse line than the system of the London United Tramways, the horses are excellent specimens and the track is kept in a highly perfect state; it needs only electricity to make it an ideal system.

It is not only, however, the inhabitants along the proposed route that will benefit from the efforts of the London United Tramways to introduce electrical working, for they are successful in inducing Parliament to grant them powers, they will have broken down the barriers that have hitherto prevented the introduction of electric tramways into London.



prises lines from Hammersmith Broadway to Kew Bridge, Uxbridge Road Station to Acton, Goldhawk Road connecting Uxbridge Road with Hammersmith and Kew Green to Richmond. The Bill, which is now before Parliament seeks to extend the Acton line to Hanwell, and the Kew Bridge line to Hounslow, connection being made between Hanwell and Brentford.

Mr. Clifton Robinson is not, however, satisfied with this very considerable extension, because he is seeking on behalf of the company powers under the Light Railways Act to carry the system to Uxbridge on the one side and Hampton Court on the other, as shown in the map. Although the scheme is meeting with much favour from inhabitants, local authorities are inclined to resist the invasion of electric tramways, and no doubt a big fight will ensue. Some days ago we had the privilege of inspecting the present tramways systems and passing over considerable portions of the proposed route, and we must confess that we have visited no

THE NATIONAL TELEPHONE COMPANY'S STAFF DINNER.

For the fifth time the members of the staff of the National Telephone Company have met and dined together. The event took place at the Trocadero Restaurant last Friday evening, and when we say that it was as successful as former gatherings we are according it great praise.

This annual meeting of the staff of the Telephone Company is an imposing, and at the same time, an interesting ceremony, because it may be regarded as the only occasion in the year that permits a representative gathering of the engineers and managers responsible for the telephone system of the country. It also furnishes an excellent opportunity for letting a little daylight into the arguments levelled against the existence of the Telephone Company.

A noticeable negative feature of the dinner was the absence of Post Office officials, so we may take it that the ardent and disagreeable reformer, who last year made their presence at the annual dinner the subject of a Parliamentary heckle, has achieved his purpose. The directorate of the company was strongly represented, though the absence of the president, Mr. J. Staats Forbes, was regrettable. Lord Harris and Sir James Ferguson were there, while Prof. Hughes, Mr. Henry Edmunds and Mr. Gustav Byng were among the principal guests.

It was a dinner of few toasts, and was, perhaps, no worse for that. Mr. Gaine, the general manager, in proposing the National Telephone Company, spoke of its healthy condition. During the past year they had opened 90 new exchanges, and had increased their subscribers by 12,000, after allowing for those who ceased to be subscribers. They had been very active during the past year in laying lines underground. The great municipalities had recognised the commercial advantages of this means of communication, and had recognised that it was advisable in the public interest to make arrangements with the Telephone Company. The consequence had been that they were enabled to make great strides in all the large English towns in placing wires underground, and bringing the plant into efficient condition. He denied that the service was an inefficient one. Where facilities had been afforded the National Telephone service would compare favourably with that in any part of the world. Mr. Gaine, in speaking of the telegraph and telephone services, pointed out that by means of the latter, 480 millions of effective messages were sent last year, while the telegraph system sent 73 millions. Then the speaker passed on to consider the telephone systems of other countries, though he did not attach very much importance to the figures. Germany, with a population of 52 millions, had 107,000 subscribers; while England, with a population of between 38 and 39 millions, had 106,000 subscribers, that is, there was one subscriber in every 300; in Germany, 1 in 400; in France, where there were 30,000 subscribers, 1 in 1,200; in Austria, 1 in 1,500; in Belgium, 1 in 680; and in Holland, 1 in 1,000. He was not going to trench on political affairs, but it had been proved by experience that competition in their business was an impossibility, the system should be under one control and that an Imperial one; it always had been a monopoly and always would be.

Lord Harris in responding on behalf of the company compared face to face conversations with the telephone. If they saw a friend across the street engaged with someone else, or if they called at his office when he was engaged, they had to wait till he was disengaged. The same thing applied to the telephone service. If a subscriber used the telephone to a very great extent, the real remedy was to have more instruments. All they asked for was fair justice; they sought a fair inquiry, and they did not fear the result if the judges would hear not merely those who condemned them, but those impartial critics who were judges of the difficulties of telephony.

The toast of the guests was responded to by Sir James Ferguson, and shortly afterwards the gathering dispersed.

THE EXTENSION OF THE PARSONS TURBINE PATENT.

The steam turbine is so very new an application of the direct action of steam, that we think every one will concur in the extension of the patent for a further term of five years. Now that the turbine has established itself as an economical steam engine and has, in the "Turbinia," given the world a taste of its qualities, we think the patentees will be able to look after themselves fairly well during the period of extension. Undoubtedly engineers have required a good deal of bringing round to the side of the turbine, and we believe they were at one time equally sceptical in regard to that other direct user of steam—the injector. Like the steam turbine the injector has a peculiarly economical side. Excepting so far as it has to lift its water supply we cannot see how the injector spends any heat excepting only what it loses by radiation, for all the steam it uses is returned to the boiler whence it came either as heat or in the form of motion of the water jet, which becomes converted into heat by friction with the water in the boiler. In the steam turbine a loss common to all heat engines of cylinder type is entirely avoided. We refer to the loss due to the phenomena of cylinder condensation and re-evaporation. These arise from the varying temperature of the working fluid, be this steam or the products of exploded gas, and the endeavour of the cylinder to approximate its temperature to that of the fluid in contact with it. The cylinder metal is in a continual state of change of temperature, and this is a condition which is universally conceded to be extremely inimical to the possibility of economical working. In the steam turbine, however, the working fluid flows in a steady stream through the various passages. True it falls steadily in pressure as it passes from disc to disc, and its temperature continuously falls also as it progresses towards the exhaust outlet. But at any one portion of the turbine passages the steam which passes that portion always presents itself at one steady temperature, and as this steam passes forward to other portions of the turbine passages, 1 inch, 2 inches, 7 inches or 2 feet distant, it will still encounter surfaces at each portion of its route which are at its own temperature. There is no interchange of heat between the turbine and the fluid passing through it unless it be the small amount required to make up any slight radiation losses. The steam will lose some heat by conversion into work, and to such extent will become moist, but the moisture will not be re-evaporated by the metal of the turbine; it will simply be carried along with the steam, and to some extent will retard the flow of this steam, and generally it will, we should say, act prejudicially, but only in a mechanical sense, and even this slight condensation will be prevented by a little initial superheat sufficient to provide the heat which disappears, or a portion of it. Indeed, the free expansion of the steam itself which probably occurs without performance of work will be effective to some degree in making good the heat which is changed into work. The enormous velocity of steam and the difficulty in applying such velocities to direct driven mechanism have been against the success of the direct use of steam. These difficulties have been very well overcome in the Parsons turbine, and such as they are, they are counterbalanced by the entire abolition of that *bête noir* of the reciprocating engine, loss by cylinder condensation—a loss which, though by some considered to be over-estimated and to be partially debited to leakages, is nevertheless a very serious item. The turbine, like the dynamo, can laugh at balancing troubles. If only made well and balanced, as pulleys are balanced, it ought to run without vibration at the highest speeds. With five years for further effort in front of them, we hope to see greater improvements still effected in the economy of the steam turbine by its makers.

THE PURIFICATION OF SEWAGE EFFLUENT BY ELECTROZONE.

We have been favoured with a pamphlet, "The Sterilisation of Sewage Effluents and Purification of Water Supplies by the Electrozone Process," containing reports made by Prof. Henry Robinson, Prof. A. A. Kanthack, and Dr. Samuel Rideal. The introduction of this pamphlet begins as follows:—"Under the patents owned by the British Electrozone Corporation, by the application of a current of electricity to sea water, or to an artificial salt solution, a steriliser, deodorant and purifier, called Electrozone, is obtained."

Electrozone is then no longer what a well-known Q.C. said in 1896 before the Board of Trade, something in which "there is neither electricity nor ozone."

We are not told what these patents are, nor what sort of electrolytic plant was erected near the outfall at Maidenhead in December, 1897. What strikes us *primâ facie* is that the conclusions of these reports are much more favourable to this electrolytic disinfectant than the previous reports made during the last few years by specialists and scientists on the same disinfectant.

We must be pardoned if we declare that we do not merely see in this the question of the deodorising and sterilising power of an hypochlorite of sodium produced by electrolysis. The discussion of the bacteriological reports of Messrs. Robinson, Kanthack and Rideal on the germicidal properties of chlorine is not in our province; the main point which interests us is the production of the chlorine, and, to a certain extent, we should be justified in complaining of the reticence of the experts on the electrolytical question.

"As regards the efficiency of production of chlorine (expressed in grains of chlorine per Board of Trade unit), says Prof. H. Robinson, I have carefully analysed the figures contained in the daily reports from Maidenhead, and have made special trials with a view to ascertain the best conditions of working such as I could obtain from plant of a more permanent type than that now in use. Upwards of 3,000 grains of chlorine can be produced per Board of Trade unit in regular working with the existing plant, but I have obtained efficiencies, even with this plant, for short periods as high as 4,939, 4,813, 3,784, 3,538, 3,430, 3,420, 3,230, &c., and I am confident that much higher efficiencies than have hitherto been obtained in continuous working can be obtained in permanent works where the detailed arrangements of the plant and of the working are properly considered.

"In my estimates of the costs of the electrozone system, given hereafter, I have adopted only 3,500 as the efficiency to be relied upon in properly equipped plants for permanent work."

We do not in the least deny the disinfecting properties of electrozone; the whole affair is a question of £ s. d., but once more we must protest against the misleading name of Electrozone; it is simply ridiculous. "Electrozone" made by chemical means is Eau de Labarraque, hypochlorite of sodium or potassium; made by electricity, it is the Hermite electrolytic hypochlorite.

We must defer giving our opinion until we know something more about the electrolytic installation, the voltage, the amperage, the nature of the electrodes, the density of the electrolyte, &c. How much chlorine is produced with different densities of electrolytes? What is the yield of chlorine per kilowatt when the electrolyte used is sea water, and when the density of the liquid is 5, 10 or 15° B? This is rather important, as when tons of chloride of sodium solution are run into the sewage effluent, there is an enormous quantity of salt lost, owing to the considerable proportion of undecomposed salt.

We are decidedly partisans of the electrolytic production of chlorine for the purification of sewage. Whether it will be by the Webster, the Hargreaves, the "Electrozone," or any other process, is rather immaterial to us. In this respect we are like Iago, who does not care "whether he kills Cassio or Cassio him, or each do kill the other."

Provided we have plenty of chlorine at a low price, we are satisfied. Will it be the chlorine of the Electrozone that will solve this problem? This remains to be proved. And it is not out of place to ask what has been done by the American Electrozone Company during the last three years? Has it sterilised the effluents of Philadelphia, Boston, Chicago? We remember having read some very promising American reports on the purification of sewage by Electrozone. Is it possible that this work of sanitation has been discontinued, and if so, why?

We should like to see that the disinfecting liquid formed by the electric current is a great and indisputable success.

But although Messrs. Robinson, Kanthack, and Rideal may be very good electro-chemists, and know how to get the highest yield of chlorine from an electrolysed chloride of sodium solution, we are very desirous to be enabled to investigate the electrolytic method adopted by the British Electrozone Corporation and its superiority over other electrolytic processes.

We ought to have, for instance, one or two reports prepared by electro-chemists of high standing who would tell us how much chlorine is produced in a continuous process for a given expenditure of electrical energy in sea water or other cheap chloride solution. In plain words, we want to know the cost of chlorine per kilo.

There has been a good deal of controversy on the quantity of chlorine produced per ampere-hour, since the publication of the report, by some known experts, who stated that 1·45 grammes of chlorine was produced by 1 ampere-hour and 5 volts, equivalent to 80 kilos of chlorine per 272,300 watts. Prof. Robinson says that he can get 3,500 grains per kilowatt. This would make 226·64 grammes per kilowatt; and in round figures 272 kilowatts would give only 41 kilos 646 grammes, about half of what the Hermite experts, Raoul Pictet and others found.

We are the more inclined to insist on this, as Dr. Samuel Rideal himself, one of the scientists who report on this Electrozone process, does not seem to find that the electrolytic work is either admirable or perfect, since he says: "I estimate that the amount of available chlorine in the form of Electrozone could be obtained from a much smaller quantity of salt, whilst the power and labour would not materially differ."

We are asking in 1898 almost the same questions which Dr. Rideal asked in February, 1894, in a letter to *Industries and Iron*, in which he said:

"When we come to consider the behaviour of chlorine as a bactericide, the case is entirely different, as, without doubt, in order that it may be an effectual germ destroyer, sufficient of this element must be present over and above that required for the oxidation of the products of decomposition. It is very doubtful if the oxidising value of the Hermite liquor is sufficient to perform both these functions, and the adverse report on the sterilisation of the sewage at Havre points to the soundness of this conclusion."

"When information is forthcoming as to the actual quantity of salt electrolysed in the water, and the amount recommended for treating a given quantity of sewage, it will be easy to see whether the inventors of this process have made due allowance for the oxidation of the organic compounds which are associated with the bacteria whose destruction is aimed at."

His conclusion, then, was that it was desirable to obtain the following data:—

"1. The quantity of sea water electrolysed, and the efficiency of the electrolysis, *i.e.*, what percentage of the salt in the water is dissociated.

"2. The quantity of sewage treated, and the amount of chlorine required to oxidise it.

"3. The surface of metal exposed to the action of the electrolysed sea water, its rate of flow over it, and the loss of free chlorine in the passage of the water from the electrolyser to the sewage."

THE WAYS OF MUNICIPALITIES.

The electrical industry of this country is affected far more than it should be by the moods and fancies of Town and District Councillors, Vestrymen, and others. The scientific knowledge of these local dignitaries is seldom so accurate or extensive as it needs to be to make fair and reasonable criticism possible. The sum total of the knowledge of which they are possessed is, in nine cases out of ten, information read in some quasi-scientific publication specially intended for their edification, or in a daily or weekly newspaper. Of course there are exceptions, for in certain boroughs—few and far between—there are chairmen and members of electric lighting committees whose methods of dealing with electrical matters might be assimilated by the many councillors who have more delight in a heated squabble or a paltry quibble than a legitimate and reasonable discussion.

This is one of the evils attending the municipalisation of electrical undertakings, and as one occasionally sees how disastrous are the effects of the municipal magnate's ignorance upon the settlement of a question of this character—often delaying the carrying out of electrical works for several years, or tying the hands of those managing existing plants in an unreasonable manner, and hampering them in the fulfilment of their duties—then it is that one is convinced that the evil is of no mean proportions, but represents a state of things requiring to be grappled with.

To convince councillors that they don't know of what they talk is no easy matter, to instruct them were a better manner of dealing with them. If matters are to be satisfactorily settled, the municipal man must keep silence on points with which he is incapable of dealing. Otherwise there will be repetitions of the blind leading the blind with the usual result.

To merely state half the truth may sometimes do more harm than a downright falsehood, and the question of half truths is making itself felt in certain parts of the country at the present moment where electrical schemes are being considered. Some councillors having made up their minds to oppose a scheme make a practice of bringing forward facts and figures showing that similar undertakings have been failures in other towns, but they fail to mention or to take into account in any way the more numerous instances of successful and profitable operation which would far outbalance the quoted failures—if they are genuine failures.

The municipal mind is not beyond reproach. There is even now such a thing as unfairness and corruption in English municipal life. But that it should have touched electrical work is a matter to be deeply deplored. That contractors or promoters should lend themselves to practices making municipal corruption possible comes to us as a surprise, and calls for a complete exposure.

Our contemporary *London* has been waging a righteous war in the camp of the Hackney Vestry, and has also been making certain investigations which do not redound to the credit of Fulham. In regard to Hackney, it will be remembered that for several years past there has been trouble *re* the electric lighting question, and the chairman of the Electric Lighting Committee seems now to have a burning desire that the Vestry should hand its provisional order to a private company upon certain conditions, and insert in the agreement a clause of early purchase if desirable. He considers that loss is certain, and we remember being present at a meeting of the Vestry a few months ago when this gentleman brought forward some figures of municipal plants which he said had resulted in a loss. His statements showed that he had inquired into the electric lighting question less than an electric lighting committee chairman should do, for he quoted as losses plants which are earning a profit. The Vestry consequently invited offers from companies willing to purchase the powers, and one of the offers sent in has been seen by *London*, and is quoted from at length. Curiously enough, the electrical engineer of the very successful municipal electrical works at Brighton—who, as most of our readers have heard, is now connected also with the British Thomson-Houston Company—champions the cause of the company, if *London's* statements be correct, by trying to dissuade the Hackney Vestry from doing exactly what he has been enabled to do with so great success at Brighton. It appears that Mr. Wright says that it would be an almost inevitable loss due to mistakes of policy and system during the first risky years of such a business. We quote: "The serious nature of this risk may be judged from the fact that all the following municipalities who put down their own plant made last year in their electricity departments very considerable losses, which in nearly all cases had to be made good by the ratepayers," this statement being followed by names of 26 towns. Our contemporary's reply to this is worth quoting here:—

The list of places has been ingeniously selected. They either refer to works newly started or to places which have committed mistakes which a town now starting would avoid. Islington, for instance, had only a loss last year of £318, which is more than wiped out by the profit of the first quarter of this year. Mr. Wright ingeniously omits Hampstead, which in the second year of its enterprise had a surplus profit of £1,832. The loss in St. Pancras was incidental to the expansion of the undertaking. The profit in the previous year was £1,200, and on the whole of St. Pancras this enterprise has been profitable. The loss in Aberdeen was trifling, and in the previous year there was a profit of £435. Scotch towns do not seek to make a profit on such undertakings. The loss in Leicester was only £265, in Bolton it was £101, in Hanley £188, and in other towns the amounts were not "very considerable." But we decline to consider the deficits in the light of losses at all, as out of the gross profits the municipalities pay not only interest on the capital invested but set aside annual sums for depreciation of sinking fund. Judged by the same standard as companies would be, we find that the return per cent. on capital invested was as follows:—

St. Pancras	5·25	Dewsbury	7·21
Islington	3·60	Dublin	4·95
Brighton	6·83	Hanley	3·26
Bedford	3·74	Leicester	4·66
Bolton	5·51	&c. &c.	
Cardiff	3·64		

Only in three places which Mr. Wright mentions was there an actual loss. Mr. Wright could have very easily selected a list which would have been convincing to the people of Hackney. He could, for instance, have cited Tunbridge Wells, which in the first year of its enterprise had a return of 11 per cent. on its capital and a surplus profit of £887, and other places where the first and second years have turned out profitable, and where the profits on the third year wiped out all the small deficits. Mr. Wright could have gone further, and shown how the municipal works in Brighton which he manages make a profit of £6,000 a year; how Bradford brings a return of nearly 12 per cent. on the capital invested; that Manchester made a profit of £17,000 last year, Edinburgh a profit of £3,400, and so on. Nor is it right to make comparisons with other places where the production of electricity is not mixed up with the disposal of dust, as is contemplated in Hackney. This entirely introduces a new condition of things, with possibilities of enormous economies, as Shoreditch is already demonstrating.

Our contemporary challenges Mr. Wright to deny that the return per cent. of gross profit on capital invested is not on the average higher in the case of municipal electricity works than for private undertakings.

There have been all sorts of charges flying about Hackney in respect of this electric lighting affair since the offers were invited. The committee are charged with being "treated" in a variety of ways, but by whom is a question not yet cleared up. It has even been said that a cheque for £400 was paid to one vestryman and smaller cheques to others. But by whom? That is the question. If by any of the parties anxious to secure the provisional order then there is room for an immediate inquiry to be instituted. For the present, without actual evidence, we cannot bring ourselves to the belief that such a state of corruption and bribery exists in connection with electrical affairs. We do not like to think it possible, bad as the appearances are.

To turn to another matter in connection with the municipal man and electrical works. There have been in progress for some months past, two schemes having for their object the distribution of electric power over large areas at cheap rates. The scheme of the Midland Electric Corporation for Power Distribution takes in the towns of Wolverhampton, Coseley, Wednesbury, West Bromwich, Dudley, Oldbury, and a number of other places in that neighbourhood; but this company has been hindered by several of the municipal authorities. The West Bromwich Council had a discussion regarding it, and in regard to the financial side of the question one of the councillors brought forward some figures as the result of the working of nine companies, from which it is shown that the revenue of these companies was £527,938, and the cost of working £262,390, leaving a profit of £265,508, and that after setting aside £78,999 for depreciation they had distributed in dividends £179,507. These facts, taken in this way, are misleading as applied to the case of a town like West Bromwich, especially as bearing on the proposal that the Town Council should generate a supply of electric current themselves. To make the profits appear too great is a weakness of many who are enthusiastic for municipalisation, in the same way as to magnify losses is a means adopted by those championing the cause of private enterprise. Mr. Allbright, one of the promoters of the scheme, writing to the local press on the subject, points out that an analysis, not of nine companies, working under most favourable conditions, but of the accounts of all the Corporation-managed supply works in the Kingdom should be made.

He suggests that it is not fair to pick out say nine of the best and largest electric lighting undertakings working in localities where the consumption is very great, and where the price which can be obtained for electricity is still very considerable, and then on these figures to assume that such a town as West Bromwich can produce results of approximately the same description, or that such figures can even be taken as a basis on which to form a reliable opinion.

Figures can be made to prove anything, either for the purpose of municipalities or companies, and the municipal mind is powerfully influenced by them. But whoever produces them should first be assured of their accuracy, and no cooking should be resorted to for the sake of proving a case where an industry of this kind is affected.

As showing the unreasonableness of the Wednesbury Corporation in respect of this Midland power scheme, we may mention that after the promoters had been for many months negotiating, the Council at the last moment decided by a majority of eight votes to five to apply for an electric lighting provisional order in opposition to the company. The Council is acting within its legal rights, but whether the Wednesbury Council can do as well for itself as the company could by putting down its immense scheme—which would, of course, result in very low costs of generation and distribution—is questionable. However, municipalities have, in some parts of the country, treated companies in a merciless manner, for after securing powers they have often refrained from carrying them into effect, as the recent *Times* correspondence, reproduced in our issue of April 15th, goes to prove. We may, perhaps, just mention in connection with this power scheme a parallel case where gas interests were involved. There was formerly in the South Staffordshire district, a large gas company covering much the same area as the Midland Electric Corporation now proposes to do, and this gas company also supplied Birmingham. When Birmingham determined to go in for its own gas, some of the smaller authorities thought they would do likewise, and they set up their own plants in order to make a profit. Two of these authorities, at any rate, are now charging their ratepayers 4d. per 1,000 feet more, or about 12 per cent., above what they could have been charged by a large company. As these authorities, we believe, make some profit, it is seen that by their action they are not only keeping their ratepayers out of the advantage they might enjoy, but they are actually spoiling the use of gas in favour of the local rates, besides this the local authorities have incurred debts in each case of probably over £50,000. In the face of these facts, Wednesbury, a town of 24,000 inhabitants, has decided to oppose the Midland Electric Corporation and go in for its own installation, although the whole of the town is practically taken up with works, and there is very little outlook from an ordinary lighting point of view.

ACCUMULATOR ELECTRIC TRAMWAYS.

A DEPUTATION of the Blackpool Corporation, together with their electrical and tramway engineer, have issued an interesting report upon what they saw and heard on a tour through those Continental cities which have added electric tramways to their other means of locomotion.

Whether these trips in search of useful knowledge really have any influence in the decision of the questions regarding the systems to be adopted is very doubtful; at any rate, in one case, an important Yorkshire city corporation hurriedly settled the contracts for an American system of overhead trolley traction, and then sent out a deputation on a Continental tour, with their electrical engineer. Adopting a system first, and then making the grand tour, saves all bother in making reports and comparisons.

In the case of Blackpool, however, a really instructive report has been issued, with an earnest endeavour to arrive at facts regarding the results of actual practice on the Continent with the four systems of electric traction on tramways. They examined the overhead trolley, the conduit, the combined trolley and accumulator, and the accumulator systems.

Blackpool was a pioneer town in electric traction, and there the failings of the conduit system were laid bare. The deputation started out to ascertain the results of practice in accumulator traction, and it is from that point of view the report is interesting. Although it is not to be accepted as a correct comparison, nor its conclusions as authoritative, yet the information it gives is valuable so far as it goes.

They find that many disadvantages which were discovered in early accumulator systems have been entirely overcome, that the system is quite practicable, and has some advantages peculiar to itself; and the only reason why they cannot adopt it is one of expense. An accumulator system, to be worked successfully, costs much more in capital outlay and in maintenance than a trolley system, but not quite so much as the Blackpool deputation estimates.

The members do not take account of recent improvements in accumulators whereby an output of energy of 13 watt-hours per pound of battery has been reached; that is, nearly double the output of cells used for traction on the Continent. It may be said that these results require confirmation in practice before being considered, but still they show that the cost of battery traction (and that is its chief drawback) is being considerably lessened.

Then in calculating out the relative costs, no allowance is made for the fact that a battery charging plant costs less on capital outlay and in maintenance, and works at much higher efficiencies than a trolley traction power plant.

In the trolley system the power factor is very low, with the battery method it can be made over 90 per cent., while in the case of the trolley it is under 40 per cent.

The dynamos and engines in a trolley plant require to be large enough for the maximum current while running most of the time under half load, and the whole question has not by any means been decided by the report of the Blackpool Corporation deputation. The cost of current at a battery charging station properly laid out would be less than the cost of current from a trolley station, and still less than that from an electric light plant.

At present, of course, the accumulator electric tramways are in their development stage, while the trolley is in its fully matured state, so that corporations are not inclined to undertake much in the nature of experiments; but all the same accumulators go on improving, and we hope in the near future to find this system an active competitor with the successful trolley system.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

ON Thursday evening last week the Institution of Electrical Engineers met to resume the discussion on Mr. Robert Hammond's paper: "The Cost of Generation and Distribution of Electrical Energy."

Mr. Preece being unable to be present, sent a written communication thanking the author for his excellent paper. Prof. Kennedy opened the resumed discussion by expressing his intention of, as time was short, not wasting any time in flattery. His succeeding remarks showed, however, that he fully appreciated the value of the paper. He endorsed Mr. Crompton's opinions, and thought that to those who are dealing with the question of costs everyday, figures tell a great deal, and are readily capable of interpretation. An immense number of points might be dealt with, and things said, but he preferred to confine himself to one or two matters of some importance.

He did not regard with favour the method of arriving at *ideal costs** by taking the best figures from different stations, as we do not know how or why the various items are co-related. It is impossible to get the very best results for them all in any one works. Again, the table (No. XII.) showing load factor and units used in distribution, tells more distinctly than any other how complex the problem is; different systems astoundingly far apart, give more or less the same result. He hoped the uncomfortable person who thought he had discovered the *best* way of distributing electrical energy by a particular system, was dead and buried, as anyone who thought there was one, and only one, way of running a station, might learn something from a perusal of the figures in the table cited.

It would be foolish to deny that load factor is a very important matter, but he would not put it so high as Mr. Hammond does. Of course, if one could manage to get a nice comfortable rectangle it would be a boon, but the fact should be faced that apparently we shall always get a peak. Even if one could aim at a load diagram giving a rectangle, the rectangle in summer would enclose a much smaller area than in winter. Take the two Newcastle Companies, for example, with widely different load factors; it is a remarkable thing that the costs are practically the same, and the coal item is even higher for the company with the larger load factor. Many other features as striking as that might be cited.

Comparing the Charing Cross and Westminster Com-

* See page 305, No. 134, Vol. xxvii. of the *Journal of the Institution of Electrical Engineers*, or page 59 of the paper in proof.

panies, the costs are practically of the same order, and there is nothing to indicate that the difference in load factors affects the results at all proportional to what one would suppose. One might draw a curve from left to right horizontally or diagonally on Diagram III., showing units per 8-C.P. lamp per annum, and works' cost, and base almost any argument upon it, the conclusion being that the whole problem is so complicated in electricity supply that individual differences do not affect the result sufficiently to leave their mark. If the author had done nothing else, this deduction from his paper would have been valuable.

The engineer factor is a very big factor indeed, but can't be put on a curve. Prof. Kennedy does not suggest that the form on Table XVII. (p. 342 of the *Journal*) is any better than any other, but it is conveniently sub-divided to show the whereabouts of the remainder, after units sold to consumers, which should be known to the engineer in charge. When he had added up the losses and the quantity sold, a balance with the amount said to be generated should be obtained. He did know that in some cases the balance was struck within 1½ to 2 per cent. of the whole, and believed it was very much worth everyone's while to know it. Many items fall *pro rata* as the units increase, but stations are not working quite comfortably when up to ·4d. per unit has to be paid to the parish authorities.

Mr. Raworth first referred to the paper as a magnificent result of Mr. Hammond's labour on behalf of all those who had to do with electricity supply, and remarked briefly upon its bearing on the schemes for general supply of electric power over large areas. The personal element tells at once in a station. Thus, at Huddersfield, the item of oil, waste, &c., had been reduced to an infinitesimal 0·02d., and the most curious thing in the world is that this station is equipped with open type engines, which certainly do throw the oil about. Compare this remarkably low figure with stations at the end of the list, and it is found that several are using up to 0·40d., or 20 times the cost of oil, &c., at Huddersfield, while many stations spend actually less on coal than these latter do for oil, &c.

Coming to staff and management, it is apparent that London companies are much more liberal than municipalities. Some companies, such as the City of London, will never be able to show any record figures, as owing to the day load being variable, due to clouds passing over, a large staff, and many boilers under steam are the rule. The moment a man becomes financially interested in an electricity supply company he cannot be happy while the sun shines, and positively gloats over a fog. Prof. Kennedy, Mr. Raworth thought, was right, as works cost is not much improved by load factor. The effect is marked only when the increase of load factor is large enough. Thus the total cost of production in a certain works where a steady demand existed for 24 hours daily was 0·28d. per unit.

Mr. Shoolbred explained at length the use and effect on cost of batteries in low pressure stations, and thought they had a specially important bearing on financial results, in addition to simplifying regulation and acting as a reserve. He fancied that an electricity supply system ought not to differ from other supplies (gas and water), and cited the saying of gas engineers, that until storage is used electricity supply cannot be on a par with gas supply. Particulars of the load curves and cost of production at Birkenhead and Bradford were given, and it was shown that with small loads batteries are of great utility, but diminish in value as the load rises.

Mr. Patchell agreed that "salaries" ought logically to go into *generation* costs. He believed the statement of Mr. Arthur Wright that at Brighton the "charge is 1½d. per unit for all consumption beyond the average of one hour per day" was a most unhappy statement. So many people stopping short at the word "consumption." Mr. Patchell is by no means the only one who has found a wide-spread belief in this direction. He characterised *ideal costs* as "crazy patchwork." One station with 380 kw. installed and maximum load of 190 kw. is referred to in the table, and such should have practically no repairs. The Charing Cross Company found their theatre load lead to sudden calls upon the plant owing to rehearsals, and necessitated considerable stand-by machinery, thus affecting steam used and boiler losses. He wished he could get a huge, big, thumping battery, and rely on it. The speaker then drew attention to the care that must be taken if accurate results of *units generated* are desired, and thought stress should only be put on *units sold*. He noted that the sudden rise in "rents, rates, &c.," item synchronised with the new assessment in London.

Mr. Addenbrooke pointed out that the "load-factor" did not take into account how the units were generated before or after the time of maximum load: the rest of the load will vary with the breadth of maximum load in two load curves having the same maximum and factor. He elaborated this point by showing how the costs are affected by varying qualities, and mentioned that an article from his pen had appeared in the ELECTRICAL REVIEW some 18 months or two years ago bearing on the matters under discussion.

It was noteworthy that at this point the statement was made, that although Mr. Wright had in a bold way called attention to the incidence of works' cost, the matter was perhaps being pushed a little too far, and people were penalised who wanted to use the current for a short time. We have had indications that a feeling is gradually growing that the present Brighton scale is not perhaps quite fair to the short-hour consumer when the supply is under the control of the municipality, although perfectly logical from the works engineer's point of view.

Mr. A. J. Lawson showed that the interest, &c., on capital on London stations as an average represented (taking 50s. per lamp for the capital expenditure) 3d. per unit, and that, therefore, a unit could not be sold for much less than 4d. He next indicated that the heavy salaries and management charges in London tend to prevent very low prices in the metropolis, and deplored the multiplication of generating stations by every little local authority. He found that the day load caused by the trams at Dover reduced the works' cost 1d. per unit. Regularity of supply is not peculiar to continuous or alternating supply, while the loss is only slightly different. In the case of two stations he had to do with :—

RICHMOND.	WANDSWORTH AND ST. LUKE'S.
Direct current loss was 10 per cent. only. Economy in small stations of batteries very great, as one shift of men suffices.	Magnetising loss on the alternating system did not exceed 15 per cent., owing to care taken in switching off idle transformers.

Mr. Sayer proceeded to explain how losses could be separated and classified in direct current and alternating current stations. The load factor he thought was controlled by the tariff. At Bournemouth—

1895.	1896.	1897.
8d. per unit.	7d. with rebate.	7d. with rebate.
7·1 per cent. load factor	11·2 per cent.	12 65 per cent.

Expensive coal might be cheaper than low price coal. The calorific value is not much guide, as the hydrogen calories are practically useless in a boiler furnace. Mr. Sayer's remarks are worthy of attention when the authorised report of the discussion reaches our readers.

Mr. Gadsby gave an equation representing the price he thought a corporation ought to charge for supply, say, to trams or similar load:

$$y = \cdot 002\,x + 100$$

where y = £ monthly paid for current

and x = units taken monthly.

Mr. Cowan believed that the mean radius of supply from mean centre of supply influences the cost of supply, and briefly discussed the incidence of distance to which units are distributed upon works' cost.

After Mr. J. W. Swan had contributed to the discussion, Mr. Hammond replied. His principal points were: the Board of Trade should amend its form so as to give us all the facts and actual figures; no difference should be made between companies and corporations; the form should embrace schedule of losses and statement of units, which should be made an integral part of the accounts. No works has reached finality in capital expenditure. Mr. Hammond rather set himself to press home the objects of his paper than to meet critical remarks, as time did not permit a full reply.

The meeting then adjourned the formal and proceeded to the informal discussion.

ELECTRICAL ENERGY (GENERATING STATIONS AND SUPPLY).

Viscount Cross presided on Thursday last week over the first sitting of the joint committee of the House of Lords and Commons appointed to inquire into the above subject. At the commencement of the proceedings a large number of applications were made by gentlemen representing companies, local bodies, &c., asking to be allowed to be heard before the Committee by counsel.

The Chairman said the Committee would consider that question later on in the day.

Sir Courtenay Boyle, in reply to the chairman, said he was the permanent secretary of the Board of Trade. The number of orders which had been granted since the year 1888 for electric lighting was 316, and at the present time there were 274 still in force. The total number of electric lighting licenses in the same period was 25.

How many of them exist at the present time?—Only three. Witness said that they took the period since 1888, because the Act of that year extended the tenure to 42 years, during which the local authorities could purchase the undertakings.

Although the particular Act refers to electric lighting only, there is no limitation in the Act?—No, but the procedure under Electric Lighting Acts has always been for the provision of energy for electric lighting purposes, but that energy could be used for lighting, telephoning, for propelling vehicles, or for cooking, or other purposes.

As regards powers of compulsory purchase of land?—The Board of Trade have no power under the Electric Lighting Act to authorise by order the acquisition of land for such purposes otherwise than by agreement. As a consequence of that, no lands are scheduled in the orders. The fact is, the undertakers get their land by private agreement.

I presume you have acted upon the general principle that electrical works, *primâ facie*, ought to be conducted without causing a nuisance?—The Board of Trade have always had that in view, but, of course, it is very difficult to avoid vibration, smells, &c.

As to compulsory powers of purchase, what are the sort of considerations that arise?—The first consideration is, is it desirable that there should be large generating stations, and that is a point upon which I have very little doubt the Committee will have a great deal of expert evidence. From one point of view there are great advantages in a few large generating stations supplying energy in large quantities under specially guarded circumstances and conditions, but if that is done the generating stations must, in the nature of things, be outside the area of supply of the various undertakers. Consequently there would arise the necessity for more frequently breaking up the streets. At present you have the generating stations of the undertakers in the area of supply, and they break up the streets. In London, as a general rule, there are two undertakers in every parish who supply electricity. If, in addition, you have a generating station outside the area of supply, you will get another party breaking up the streets. On the other hand, the difficulty of acquiring sites is unquestionable. Undertakers find it very difficult to acquire sites for generating stations. Generating stations must be an inconvenience, but they need not necessarily be a nuisance.

Undertakers are prohibited from supplying energy or erecting works beyond the area of their supply?—If they do so there is power to revoke the order.

But there is nothing to prevent their erecting generating stations outside their area, provided they can get leave?—The local authorities in some instances have given undertakers power to break up streets outside their own areas. The law officers have advised the Board of Trade that such a proceeding is *ultra vires*.

If you have generating stations outside the area of supply, there is a difficulty when the question of purchase by the local authorities comes to be considered. That is a very great difficulty, and undoubtedly there must be some inconvenience caused.

What is the period of purchase generally?—Forty-two years, as a rule. It is variable, however, by provisional order.

On the question as to what pressure should be allowed, the Witness said that no doubt the Committee would have witnesses before them who would say that it was just as easy to convey electrical energy at a very high pressure as at a low pressure, but perhaps they might hear from others that electric energy was like a wild beast in a cage, always trying to get out. For ordinary purposes, 3,000 volts might be considered high pressure, but the Board of Trade had given power in certain cases to a higher pressure than that.

About the telephone and telegraph systems; are you afraid they might be injuriously affected by high pressure mains?—Well, there is no doubt that high pressure currents, if there is anything like leakage, are a considerable danger to the telephone and telegraph systems, and there is considerable danger caused by leakage from high pressure mains. Sir Courtenay Boyle then referred to the Bill of the General Power Distributing Company, and of an application which had been made for a provisional order for the supply of electric energy in a large area in the Midlands from a generating station situated at Wolverhampton, and said there were many important questions which would have to be considered before those powers were granted.

None of the companies have a monopoly?—Oh no. They have no monopoly, and it is contended by the promoters of this Bill that if they get the powers they seek, they will be able to supply electrical energy for the use of mines, factories and lighting purposes at a very low price. The Witness, continuing, said he was unable at that moment to give the Committee accurate information as regarded the generating systems of America and Germany; but he would take care to give the Committee information on that point at a later stage. It would be very difficult to apply the principle of purchase by local authorities to such a case as the General Power Company; in fact he did not see how it could possibly be done.

By Lord Knutsford: He would not give local authorities power to compulsorily purchase works outside their own area.

Replying to Mr. Kimber, Witness said that if generating stations were a long distance from the area of supply, the voltage power allowed must be higher than if the station was in the area.

And in consequence of that, the interference with other electrical industries, such as telephones, telegraphs, electric tramways, &c. would tend to be very serious?—My own opinion is that it would tend to increase the risk of interference; but there are many electrical experts who do not think so.

Lord Balcarres: What was the reason which led the Board of Trade to allow two competing companies in every district in London?—Witness replied that that was really the result of a compromise, arrived at after a very long and elaborate inquiry in 1889, which was held with a view of determining whether competition in London should be allowed, or whether companies should be granted a monopoly. It was held as a compromise that it was desirable to grant two companies power over the same area.

And that gives a certain amount of competition?—Yes.

Is there any parish in which there are more than two companies?—Yes; there is a parish not far from here in which there are three, but there is no parish in which there are four.

Lord Morley, Chairman of Committees of the House of Lords, was next examined as to the procedure relating to the granting of provisional orders. He said that, except as regarded tramways, the Electric Lighting Acts made no distinction between light and power. All companies applying for a provisional order must be limited companies incorporated under Act of Parliament. He said that Parliament was very jealous in respect to giving compulsory powers of purchase for any purpose, and the cases in which such powers had been given were generally under the Public Health Act, where it was clearly shown that the powers would be for the advantage of the public.

Would you be against granting compulsory powers simply to a limited company?—I don't like to go quite so far as that, but it is worth while the Committee considering whether the rule should be broken. It is an important rule, and I don't think it ought to be broken without the very clearest necessity being shown for it.

If compulsory powers are to be given, there are two ways to do it; either to come to Parliament, or to give the Board of Trade authority in the matter. Which process would you agree to?—I have rather a difficulty in answering that question. On the one hand I am extremely anxious not to break down the existing system, which has worked extremely well up to the present time by provisional order; and on the other hand I am reluctant that Parliament should give up its powers. It has been suggested that it might be possible, where companies require compulsory power, that they might come to Parliament first, and then go to the Board of Trade; but I think that would be too expensive and cumbrous.

Lord Knutsford: On the whole you are in favour of compulsory powers being granted only to companies that are incorporated?—Generally that is my opinion.

Of course companies cannot be incorporated under a provisional order, and therefore parties applying for a provisional order must be incorporated to meet your views?—Yes. Continuing, the Witness said that that delegation of compulsory power to the Board of Trade would throw a lot of extra work upon the department, and would introduce a new element of contention when provisional orders were asked for.

By the Chairman: It seems to me a very common sense point of view that it is desirable to get these large generating stations out of the large centres of population, the same way as gasworks are; but there are difficulties in the way.

By Mr. Kimber: He was not prepared to say that he would recommend the insertion of a "nuisance" clause if compulsory powers were granted, but he thought the Committee might very well consider how far these generating stations could be worked without creating a nuisance.

Lord Balcarres: With regard to the difficulty of purchase at the end of 42 years—is it at all likely that a local authority would wish to buy mains without plant, or plant without mains?—I should imagine not.

Need we take that into consideration when coming to a decision as to whether outside generating stations should be allowed or not?—Well, I believe thus far all the generating stations are within the area of supply.

Mr. Kimber: Excepting Deptford.

Lord Balcarres: But in the event of this General Power Distributing Company and this provisional order for the Midlands being passed, there would be two fresh cases in which a great central station will supply energy from points at from 12 to 26 miles distant?—That is so.

In considering this scheme, do you consider it necessary that we should contemplate that at the end of 25 or 30 years the local authorities would wish to buy bits of plant?—Of course it would be absurd for the local authorities to buy bits of plant.

By Lord Knutsford: It was quite possible they might wish to buy pipes in their own district, and have powers over them.

Mr. Chandos Leigh, Q.C., the speaker's counsel, was then briefly examined, and said that, generally speaking, he endorsed what the two previous witnesses had said.

The Committee then consulted in private for some time, and on the re-admission of the public the Chairman said the Committee had been considering the course of procedure in the matter. He wanted to call attention very specially to the exact order of reference, which was as follows:—To consider and report: (1) Whether, notwithstanding the provisions of Section 12 (1) of the Electric Lighting Act, 1882, powers should be given in any cases for acquiring land compulsorily for generating stations; and if so, under what conditions as respects liability for nuisance, notices to surrounding owners, and otherwise. (2) Whether compulsory powers of acquiring land for generating stations, if proper to be given in any case, should be given where the proposed site is not within the area of supply. (3) Whether, in case of a generating station, however acquired, not being situate within the area of supply, power should be given for the breaking up of the streets between the generating station and the boundary of the area of supply. (4) Whether powers should be given in any case for the supply of electrical energy over an area including districts of numerous local authorities, involving plant of exceptional dimensions and high voltage; and, if such powers may properly be given, whether any, and what, conditions should be imposed—(a) With respect to system and plant, and to the construction and location of generating stations, in view of the powers of purchase conferred upon local authorities by Sections 2 and 3 of the Electric Lighting Act, 1888; (b) with respect to the relations of the promoters to other undertakers and to local authorities within parts of the area. (5) Under what conditions (if any) ought powers to be conferred upon promoters seeking to supply electrical energy to other undertakers and not directly to consumers. The Committee had determined not to travel out of that record by one single inch, and they would have nothing to do with particular Bills which were before Parliament at the present moment, as they were only there to discuss questions of general principle. They had also decided that all applicants who desired to be heard should send in their applications in writing, stating the particular points upon which they wished to be heard, and the names of the witnesses they wished to bring. As regarded counsel, the Committee would only hear one counsel upon one particular head, and the parties interested must agree among themselves as to the witnesses they wished to produce and as to the counsel.

After another adjournment, representations were made to the Committee by counsel and Parliamentary agents on behalf of the parties interested in the inquiry as to the matters desired to be raised from the points of view of various electric lighting companies and local authorities.

The Committee adjourned until Monday.

Lord Cross presided on Monday over the second sitting of the Joint Committee.

Mr. Frank King, engineer-in-chief to the Chelsea Electric Supply Company, was examined on the first head of the reference, and said that in 1895 his company acquired the reversion of a certain lease. A portion of the ground was covered by houses and shops, and in the area was a row of houses known as Steer's Buildings, and a stone-yard belonging to the Vestry. The total area of the site was 65,700 square feet. There were certain unexpired leases on the land. The London County Council authorised them to build on the site, and there was partly built a generating station thereon. The station had been constructed so as to be economical to themselves and innocuous to other people. One of the principal features to consider in making a generating station was the minimum plant required. They could put on 1 square foot of land generating plant which would light 7½ lamps at an ordinary equivalent of 8 candle-power. The houses on the site were of a very small class and in very bad order. They had a chimney 100 feet in height and one 150 feet high. The result was that the air was very much clearer than it used to be. The Alpha Place station was approved by the London County Council two years ago, and they commenced the erection of works immediately. They found great difficulty in getting the site cleared, and they had to pay extraordinary prices to get them out in anything like time, and the result was that they had been delayed very considerably while they were under statutory obligations to supply the demands of the district. In one case they had to pay £600 for a little fried-fish shop which was not worth £100. It took six months for them to safely erect a chimney shaft, and it took them at least 18 months to complete a generating station. The result was that if they were delayed six months they found they could not meet the demand. They desired to extend the station, and they had to acquire a cottage worth about £150, but the vendor wanted them to buy other property at a cost of £39,000. It was obvious that if they were to meet the growing demands of electric light, their plant must be commenced at the earliest possible moment. They had machinery ordered now, but no place to put it in. They could get on if they could get a portion of the Vestry yard, but the Vestry would not listen to any negotiations whatever. If they got the whole of the site, its capacity would be about 150,000 lamps. They believed that the area under their provisional order would absorb 750,000 lamps, and their present accommodation, adding the stations together, was for about 400,000 lamps. It was only possible for nuisance to arise from vibration or smoke and steam. For the purpose of obviating the first, they had twice substituted machinery, and they had now an engine which was absolutely free from vibration. They had eight engines at work at present, representing over 2,000 horse-power, and on examination in the adjoining house, they had failed to find any vibration. With respect to smoke, they burned the best smokeless Welsh coal that money could buy. They were watched very assiduously by the Vestry, and never received any complaint at all. They failed to find any condensed moisture in the neighbourhood. They did not intend to build any shafts less than 150 feet in height.

In answer to Mr. Coward, representing various Corporations, Witness said he had no objection to Corporations having similar compulsory powers to the companies.

Mr. Coward: You are seeking here compulsory powers. Do you see any objection to local authorities having notice of your seeking compulsory functions, and to them being heard if they think fit in the interest of the ratepayers?—I can understand that in the case of a new company; but in the case of an old company, I think it would hamper them.

By Lord Knutsford: The engine he referred to as being free from vibration was Willans. It was largely used by other companies. The man who wanted to sell them his property complained of the vibration.

By Mr. Kimber: There would be no objection to having the construction of the chimneys supervised so as to avoid smoke nuisance whatever the coal used was.

Mr. Kimber: Are you prepared to say as an expert that adjoining properties would not be affected by the vibration or smoke?—I am not prepared to say that.

The Chairman: Have you considered whether the action of your company would in any way interfere with the telegraph or telephone?—It would not.

Mr. J. I. Courtenay, chairman of the Chelsea Electric Supply Company, was next called, and, in reply to Mr. Coward, said he saw no reason why local authorities should not have the right to be heard before the companies got compulsory powers.

The Chairman said that was a matter of policy for the Committee to consider.

Mr. Sydney Morse, solicitor for the Chelsea Electric Supply Company, chairman of the Electrical Trade Section of the London Chamber of Commerce, and member of the Council of the Institute of Electrical Engineers, gave evidence regarding the standing orders of the Houses of Parliament before the change in 1893 and after. In a number of electrical railways Bills a clause was inserted with respect to generating stations. There would be great difficulty in incorporating electric light companies, because incorporated companies could only borrow to a certain extent, whereas the majority of the electric light undertakings had, under Stock Exchange rules, borrowed considerably in excess of the standing orders.

Answering Lord Balcarres, Witness said progress had been made to prevent nuisance arising from generating stations, but, of course, an engineer might not consider a thing a nuisance which a householder would.

Mr. Albert Gay, engineer to the Islington Vestry, said his Vestry had experienced some slight difficulty in regard to their generating station for the want of compulsory powers. They selected a site for the station which was bounded on two sides by a railway, but on one side there were several small houses they endeavoured to buy, but found a certain life interest in two of the houses which prevented them being sold.

This concluded the evidence on the first head of the reference, except that Sir Frederick Bramwell may be called. The Committee then proceeded to deal with the next two heads of the reference, dealing with generating stations outside the area of supply for the power of breaking up the streets.

Mr. Eustace Balfour said he was chairman of the St. James's and Pall Mall Electric Lighting Company, which started in 1888. He was also the chairman of the Central Electric Supply Company, which had a scheme before Parliament that session. It was proposed to acquire a site and supply electric current both to the St. James's and Pall Mall Company and the Westminster Company. The St. James's Company had had to pay very heavily for sites, and he did not know where it was possible to acquire a new site in the area. They had two stations, and there was no railway or canal convenience for bringing coal. Their coal consumption roughly came to about 200 tons a week. To get a generating station outside the area they would have to get compulsory powers to lay mains or else get the consent of the local authorities. It would, however, only mean the laying down once of a trunk main. The Central Company proposed to acquire a station in the parish of Marylebone which would furnish current to St. James's and Westminster. The demand for electric current was largely in excess of anticipation.

By Mr. Coward: The power sought to be acquired would enable the undertakers to break up the streets without the consent of the local authority, but considering the small amount of interference required, he did not think there should be any objection. He was not aware that in Manchester all the mains under the streets were acquired by the Corporation for the purpose of obtaining proper control over the streets. He was prepared to agree to a reasonable clause in conjunction with the local authorities. He would have no objection to paying a moderate rent for the use of the streets.

By Mr. Stevens: He did not know how far the principle of the General Company supplying other undertakers had gone, but if the St. James's Company had a breakdown, they would go at once to the London Company for a supply of current. The Central Company did not intend to supply the public.

Examined by Earl Spencer: The rapid growth of the use of electricity had forced them into having a central company to supply electricity to other companies.

By Mr. Kimber: In saying there would be one trunk line, he took it that they would keep others out; but still, if there was a rival the breaking up of the streets would not be what it is now.

Replying to Lord Knutsford, Witness said the Central Company had arranged to supply two companies, but they did not ask for a monopoly.

By Lord Cross: He agreed that England was behind other countries in electrical progress, and the compulsory purchase by the local authorities in 42 years had crushed many earlier attempts. He had not worked the figures out to see if it would pay to form a great central supply station to supply electricity for 50 miles round, but if it would he thought it would be a good thing.

Prof. Kennedy, F.R.S., engineer-in-chief to the Westminster Electric Lighting Company and joint engineer of the Central Supply Company, which had a Bill in Parliament to obtain compulsory powers, said that in two years' time the St. James's and Pall Mall Company and the Westminster Company would be at the end of their tether in supplying current. His company worked very smoothly with the local authorities.

Replying to Mr. Kimber, Witness said they hoped in the future to be able to supply current even cheaper. What they wanted ...

was power to be able to continue to fulfil their statutory obligations. The average price the Westminster Company charged to the consumer was 5½d. per unit. The cost of production was about 3d. per unit. He thought the only company that produced more cheaply was the Pall Mall Company. The Central Supply Company was promoted by the Westminster Company and the St. James's Company to obtain energy cheaper if possible.

By Sir Leonard Lyell: The mains they proposed laying down would not require to come up for 30 years.

By Mr. Ashton: The longer the distance away the generating station was the higher voltage would be required, but there had been no accident in London yet. The highest voltage in London was 10,000, and they only proposed to have 2,000.

Mr. Dobson, engineer to the St. James's and Pall Mall Electric Light Company, said they had had considerable difficulty in getting sites for stations in the area. They could put in enough plant in their present stations to carry them through two more winters; they would require 2½ miles of mains to connect their station with the proposed station of the Central Supply Company, and those mains could be carried through by streets.

Mr. Moss recalled, produced a copy of the Bill of the Brompton and Piccadilly Railway Act, showing a generating station to be outside the district served. The station of the Strand Company was in Lambeth, and originally at Bournemouth, the site was outside the area of supply. It was a common thing for companies to cover several areas. He thought it would be impossible to turn electric lighting companies into incorporated bodies, for all electric lighting companies were limited liability companies.

CORRESPONDENCE.

Re-winding Field Coils of Dynamo.

I have a two-pole dynamo coupled to Willans GG engine, wound to give 115 volts and 275 amperes. With my load this is attained at a speed of 350. I wish to re-wind the field coils to get 135 volts and 275 amperes at 400 revolutions. Present coils are wound with No. 8 B.W.G. wire, covered to 5 B.W.G. They heat badly at 115 volts. There are 82 coils of wire outside, measuring around outside 6 feet 7½ inches, and the depth of the windings is $2\frac{13}{16}$ inches. The inside of the coil frame is 1 foot 10½ inches by 10½ inches. What diameter of wire, covered and uncovered, should I use for the new winding, and what will be the approximate length on each pole?

Subscriber.

[There is, evidently, not enough wire on the field-magnet, and probably no room for more. To get 135 volts the speed would require to be raised to 415, and No. 10 B.W.G. wire used on shunt laying on as much as space will allow. More specific instructions had better be obtained from the makers of the dynamo.—Eds. Elec. Rev.]

Jerry Wiring.

As a wireman of about 17 years' experience, during which time I have been engaged on bell, telephone, and telegraph wiring, arc and incandescent lighting (both alternating and continuous), transmission of power, accumulator and tramway work, and also in connection with electro-chemistry, I think I may speak with some authority on this matter, and I can assure Mr. Jeckell that the jerry wiring fiend still flourishes in other places besides South Shields, in spite of regulations and testing sets. I have known personally of tests made which never reached beyond the first group of branch cut-outs, these being placed close to the ceiling and the fuses left out, and the testing inspector contenting himself with the assurance of the man in charge that all fuses were in. Turning in another direction, I once worked for a firm in this town for nearly four years, and carried out many fairly large installations for them. A slack time came and every man in the shop, except myself, was discharged for want of work. I was promised by the senior partner, in the presence of the only other partner, that if I would stand by them they would find me as much work as they possibly could during the slack time, and send me out in charge of the first decent job they got. This was about Christmas. About April I discovered accidently that they had on at a popular watering place, a job of 300 incandescents and eight arcs, and that they had about 10 men on it, all working overtime, while I and my family were scraping along as best we could on about three days per week. On reminding the firm of their promise to me, I was very coolly informed that I had not been, and could not be sent to the job, as I was too expensive, as these fellows were working for 6½d. per hour, while I wanted 8d., and asked for no expenses, whereas I had always had from the firm 14s. per week without any demur. You will see, therefore, that on a 50 hours' week, as we worked, these fellows each cost £1 0s. 3d. per week less than I did. But were they wiremen? To my own personal knowledge four of them had never done an inch of wiring in their lives, having been for a short time previously labouring for wiremen, one of them having been an outside telephone labourer. Now what can you expect under these circumstances but jerry wiring of the worst possible kind? When the better class of contractors combine with consulting engineers and insurance companies to induce the Board of Trade to oust the jerry wiremen and the jerry contractor from the business by establishing a scheme of compulsory registration for wiremen and persons in charge of jobs or electrical departments, each having to pass a practical examination before being registered and receiving his certificate, then we may kill jerry wiring, but all the exposures in the world will not do it, as they will still revert to their old tricks in dark places, such as false roofs, &c.

Wireman.

Back E.M.F.

Will you please advise me whether the method I adopt for determination of the back electromotive force (B.E.M.F.) of an electrolytic bath is correct.

At a slow speed I get at the brushes 84 volts (E) and 143 amperes (C). At an increased speed I get 116 volts (E + e) and 249 amperes (C + c).

Difference in reading 32 volts (e) and 106 amperes (c).

$$\text{The B.E.M.F.} = (E - e) - \left(e\,\frac{C - c}{c}\right) = 40{\cdot}9 \text{ volts.}$$

If this is correct, is the actual electromotive force generated in the dynamo at full speed 116 + 40·9 = 156·9 and the electrical horse-power $\frac{156{\cdot}9 + 249}{746}$?

E. D.

Steam Relief Valves.

Several serious accidents have recently taken place owing to water in engine cylinders. The small steam space in many water-tube boilers has, in some instances, contributed to this.

In the description of electric works in your columns, I have not found reference to precautions against such accidents. It appears to be admitted that ordinary relief valves cannot get rid of any serious rush of water. What are the best means to adopt? Is a large steam separator sufficient to hold, on an emergency, the water due to bad priming, or due to a burst or failure of another engine? If so, what are the proportions?

Colonial.

[Our descriptions may not perhaps make special reference to the means for overcoming the effects of priming, because these appliances are by no means general. At the same time, we have referred to such means in other articles—one recently in which we discussed the recent breakdown at Yarmouth. It is hardly possible to say how big a separator should be, but we incline to the use of a separator of the pot or U type between the boiler and engines, and we are also of opinion that engine steam pipes should branch from the top of a steam main, not from its side or bottom. We certainly would not trust to cylinder relief valves for relief of priming due to overfilling of boiler. With the steam pipes arranged as above, the steam main ought to be well drained at its lower end, and such abominations as ring mains ought not to be allowed with their multiplicity of valves and connections, which introduce far more complication and risk of accident than is likely to occur with a well-designed steam main.—Eds. Elec. Rev.]

Shoreditch Destructor.

I have been very much interested in reading the report of a deputation from Tunbridge Wells to Shoreditch. Please read enclosed copy; can you give any explanation of the very extraordinary fact that the great fun of the whole affair, "thermal storage," finds no place in the said report, also that the financial statement is now "expected" to be issued in June next—if I remember right it was to have been at the end of March—and further, that no particulars of cost, &c., for comparison could be obtained, &c.

Power.

[From the cutting enclosed the report appears to be that of a deputation from Maidstone.—Eds. Elec. Rev.]

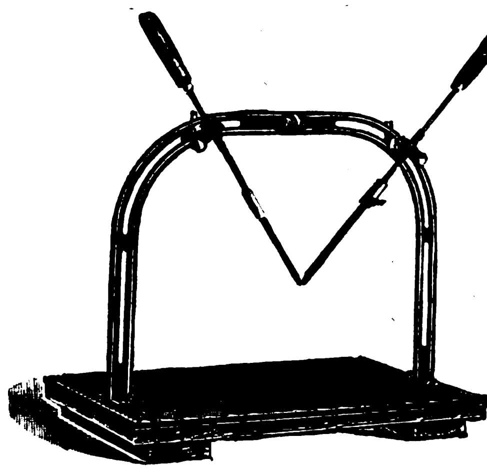
An Improved Electric Furnace, Welding, or Brazing Machine.—The investigations and experiments by M. Moissan, Prof. Roberts-Austen and others, as to the behaviour of metals, alloys, ores, and other materials when subjected to the intense heat of the electric arc, together with the practical use of electric furnaces for the reduction of ores, notably those of aluminium and others of a refractory nature, have resulted in the desire of other investigators to enter the same field and rendered the subject of some importance in technical education. The want of efficient apparatus at a low cost for the purpose of experiment and illustration has hitherto resulted in the operator manufacturing his own out of materials at his command. To meet the demands for such apparatus, the following—originally designed some years ago by Mr. W. Clark Fisher for private use—has been placed upon the market by Mr. R. W. Paul, of Hatton Garden. In the design it was sought to provide an instrument alike suitable for furnace, crucible, open hearth, welding, brazing, and hard soldering, &c., for which purpose it was desirable that the carbons should be capable of universal movement admitting of their being placed at any angle in any plane. In order to achieve this, as shown by the illustration, the framework supporting the carbon holders consists of a slotted arch of metal cast in two halves mounted upon a fire-resisting and insulating base and efficiently insulated from each other at the top where they are bolted together. The carbon holders have a swivel action fitted with thumbscrews so that they may be clamped in any position, the swivel action is attached to an insulated bolt which passes through the slots in the framework and allows of adjustment to any height. Each carbon holder having an action



entirely independent and thoroughly insulated from each other and the framework, it is easily seen that they may be arranged as in the illustration for crucible, welding, or brazing work at a suitable angle, or both placed horizontally, or one horizontal and the other vertical, &c., for furnace work, and to suit requirements. The apparatus at present is made in two sizes, one for 10 to 15 amperes at 50 to 100 volts, the other 60 to 80 amperes at 50 to 100 volts.

Chain Gear Catalogue.—We are in receipt of an advanced copy of the chain gear catalogue of Mr. Hans Renold, of Manchester, who has made chain gears a specialty, and by his peculiar system of chain has overcome the objections which formerly obtained on account of wear, which varied the pitch of the chain. In Mr. Renold's chain the variation of pitch due to wear of the pins corrects itself by the assumption by the chain of a larger radius of revolution, and the design of the links is such that they enter and leave a wheel without rubbing friction. Mr. Renold claims to be able to run these chains up to a velocity of 1,600 feet per minute, at which speeds the chain is no more noisy than a leather belt. Like many other mechanical appliances, the chain has fallen into perhaps undeserved disuse on account of its bad construction. Mr. Renold aims to make a chain perfect, and expects thereby to make it satisfactory, and from all we hear is doing well, and producing good and reliable chains equal to claim.

Change of Address.—Messrs. Allingham & Fennell, electrical engineers, have removed from 27, Bower Road, Victoria Park, to Harrow Green, Leytonstone, N.E.

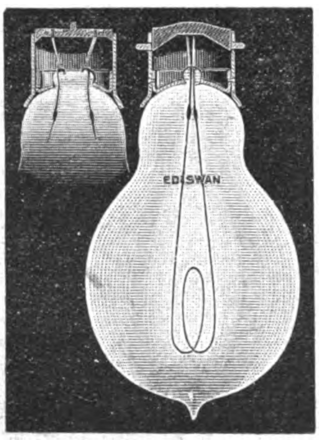
Church Lighting.—Messrs. Calvert & Company, of Manchester, have recently carried out a number of church lighting installations, near Manchester. The latest, the Emmanuel Church, Southport, was completed for the opening service on April 10th. The installation consists of some 250 16-C.P. lamps, in fittings of 26, 12, and 10 lights inside the church, and 100-C.P. lamps on ornamental posts outside, the lights being arranged so that either one-third or two-thirds may be switched on at once from the main board in the lobby. This firm have also carried out the electric lighting of St. Luke's Church, Southport.

Electric Light Cables and Wires.—Mr. Isidor Frankenburg, of the Greengate Rubber and Cable Works, Salford, Manchester, has sent us a list and samples of electric light cables and wires manufactured by him. The conductors of all the cables and wires which are given in the list consist of the best copper wire having a guaranteed conductivity of 100 per cent. of pure copper (Matthiessen's standard). In the various tables there are given dimensions, weights, resistances, and capacity of the conductors, and prices appear of taped wires and small strands, taped and braided ditto, taped and braided vulcanised electric light cables, wires and cables for aerial work, also cables and wires insulated with pure rubber. We have examined the various samples sent, and they all appear to be well made mechanically.

Electro-Zincing.—We understand that electro-zincing has been adopted by Mr. Peter Brotherhood for his air compressor tubes, and a plant is now being erected at his works on the Cowper-Coles regenerative system.

The Hook of Holland.—After many complaints, says the *Times* Rotterdam correspondent, about the insufficiency of the lights at the entrance by the Hook of Holland, the Minister of Marine has decided to ask for a credit in next Budget for two electric lights of the highest power to take the place of the present two red oil lights.

Dry Cap Lamp.—The dry cap lamp shown in the illustration is specially recommended by the Edison & Swan United Company for use in damp places or outside lighting. The lamps are specially suited for mines, pier lighting, or damp cellars, where it has been found that the plaster of Paris softens after the lamps have been in use for a little time. The cap is attached by means of a brass disc and is fastened to the glass bulb by specially prepared cement, which is thoroughly damp-proof, and the leading-in wires



are perfectly free, so that the lamp has an air insulation in the interior of the cap. It is important to note that although there is an air insulation, by using the thin layer of cement between the brass and the glass, it acts as a non-conductor and consequently there is very much less heat conducted than there would be if the brass and glass were not intercepted.

Meeting of Creditors.—At the offices of the Manchester Official Receiver, on 19th inst., a meeting was held of the creditors of James Fletcher and John Arthur Hirst, trading as Fletcher, Hirst & Co., electrical and mechanical engineers, at the Bankfield Works, Curzon Street, Burnley. The statement of the debtors' affairs showed liabilities expected to rank for dividend £2,184, and assets £424. It was stated that debts to the amount of £1,131 had been proved. The debtors made an offer of 6s. in the pound, to be paid—3s. within seven days of the creditors' acceptance of the offer, and 3s. after the lapse of six months. The creditors present were willing to close with the offer, but it was pointed out by the chairman that it was neither within their power nor that of the Court to do so. The lowest composition that could be accepted and approved was 7s. 6d. The meeting was therefore adjourned for a month, to give the debtors an opportunity of making a further offer to the amount required by the statute.

Price Lists.—Messrs. Laing, Wharton & Down, Limited, have issued some advance lists of new alternating and continuous current apparatus which they are introducing. The lists particularise "Whardown" transformers, G type, illuminated dial measuring instruments, transformers for voltmeters and wattmeters, economy coils, single-phase motors, also "Whardown" continuous current motors and dynamos and combined fans and motors. We understand that the firm attaches great value to the entirely new style of switchboard instruments which are illustrated, and although they are only listed for alternating current work, they may shortly introduce a line of continuous current ones. Special attention is directed to the 500-volt motors and motor fans in view of the demand likely to arise for motor current at this voltage in connection with the supply of current for electric traction.

Messrs. Wilhelm & Co., London agents for Mr. K. Wienert, of Berlin, sends us a list of the "Sonja" long hour arc lamp with enclosed arc burning from 100 to 200 hours for continuous and alternating current.

The Vestry of St. Mary, Battersea, v. The County of London and Brush Provincial Electric Lighting Company, Limited.—On Thursday, April 21st, Sir Francis H. Jeune, sitting as an additional judge of the Chancery Division of the High Court of Justice, resumed the hearing of the above-named action, which was brought in order to have the question decided whether the defendant company, who hold a provisional order enabling them to supply the electric light within the district of Wandsworth, were entitled thereunder to lay their pipes in Trinity Road, Battersea, part of which was, admittedly, in the parish of St. Mary, Battersea, and within the area of supply of the Battersea Electric Lighting Order. For the defence it was contended that this was not a case for a mandatory injunction, even if the defendants were in fault. Mr. R. Bray, Q.C., and Mr. Chapman appeared on behalf of the Vestry, and Mr. Cripps, Q.C., for the defendant company. The case was opened before His Lordship on March 9th, and a note on the subject appeared in the Electrical Review at the time.

On Thursday last week, when the case came up again, His Lordship pronounced judgment, and said he should have been very glad if the case could have been settled between parties, but that had been found impossible. Public bodies as well as individuals were entitled to have their rights adjudicated upon, even although they afterwards might see fit to arrive at an arrangement. Dealing with this case purely as a matter of law, the only question he (the judge) had to consider was that of the remedy to which the plaintiffs were entitled. That the defendants were wrong in what they had done, was, to His Lordship's mind, beyond doubt. The Act of Parliament approving the order under which the defendants worked, clearly defined their rights and powers, and it was equally clear to his mind that the plaintiff Vestry had vested in them—whatever the words might mean—the area in which the defendant's wires had been laid. It was also clear that the defendants had no right, without the consent of the plaintiffs, to lay their wires in that area. The defendant company was clearly wrong in what it did, and he felt bound to say that their conduct was as wrong as the principle under which they had acted, because it appeared that sometime before the particular act complained of the company had acted in a precisely similar manner, and laid down wires in another part of the same road, and when their attention was drawn to it they took up the wires and apologised. Afterwards they applied for leave to place their wires in the same area, but that being refused, they took the law into their own hands, in the manner which had been put before the Court. Under the circumstances the question was what was the remedy to which plaintiffs were entitled, and as to that he thought the case was governed by that of Goodson *v.* Richardson, which was a decided authority in plaintiffs' favour. The conclusion to which he (Sir F. H. Jeune) had come, was that the defendant company should be called upon to remove the wires in question, and that there ought to be judgment for the plaintiffs for a mandatory injunction, and a declaration as prayed for with costs. His Lordship, however, on the application of Mr. Cripps, suspended the operation of the injunction for three months, with liberty to apply in the meantime for leave to appeal.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The Gas and Electric Lighting Committee had under consideration last week the suggestions by Prof. Kennedy, with reference to the extension of the electric lighting to the west end of the city. It was decided to carry out the proposal by which the extension could be effected at a cost of £5,700. The Committee also resolved to extend the Union Street electric main at a cost of £168. The offer of Mr. Henry Brechin to supply steam coal for the electric station at 8s. 6d. per ton has been accepted.

Ashton.—A circular *re* electric lighting, drawn up by Mr. Clirehugh on behalf of the Council, is being distributed in the borough.

Bangor.—The City Council has resolved upon gas extensions, and at the same time has decided to establish electric lighting works for supplying current for Garth Road and High Street at a cost of about £10,000. Ratepayers have given a guarantee of £500 a year for the electric lighting.

Barking.—On 21st inst. a Local Government Board inquiry was held into the Urban Council's application for a £15,000 electric lighting loan. The Barking Gas Company and a body of ratepayers appeared in opposition. Mr. W. C. C. Hawtayne, the consulting engineer, explained the scheme in detail. He estimated the working expenses as 2½d. per unit, and the annual gross revenue at £2,600. After paying for working expenses and allowing for renewals and repayment of capital and interest, and assuming that in addition to the public lamps the Council supplied private consumers with an equivalent of 3,000 8-candle-power lights, there would be a profit of £309 available for the reduction of rates or other purposes.

Bradford.—The Bolton Road and Morley Street tram routes are to be lighted by means of arc lamps at a cost of £500 a year. The charge for lighting current is to be reduced from 5d. to 4½d. per unit, with a sliding scale for the motive power.

Belfast.—The engineer recently presented a report on the comparative cost of electric and gas lighting for streets, with particular reference to some of the main thoroughfares, which, briefly summarised, conveyed the information that the present method of lighting the principal streets is, if considered sufficient, the cheaper, taking into account the fact that it is done at a loss; but if electric current were employed for the purpose, 3·75 times the light could be given for 2·2 times the cost, without loss to the department, while the ordinary street lamp could be replaced by incandescent electric light at the price at present paid. The report, in an amplified form, will again come before the committee.

Chislehurst.—The Board of Trade have approved of the Chislehurst Electric Lighting Order.

Croydon.—Mr. G. W. Willcocks held an inquiry at Croydon, on behalf of the Local Government Board on Tuesday, respecting the application of the Town Council to borrow money for the purpose of additional plant in connection with the electricity works, for additions to the electric lighting station buildings, and for £1,000, the sum payable by the Corporation to the British Thomson-Houston Company, Limited, upon the Corporation determining the period of working at the end of the first year, as referred to in Clause 18 of the agreement dated March 12th, 1896, and made between the British Thomson-Houston Company, Limited, and the Corporation. The total amount required by the Corporation is £6,772; but the inspector said an item of £2,772, required for the additional plant at the electric lighting station, did not really come within the scope of that inquiry. Alderman Miller said they asked for sanction for these items in consequence of the increased demand for supply. They already had double the number of customers, and were still increasing at the rate of about 150 lamps per week, and they were compelled to hold over applications until additional plant was put. Unless they got this by September, they would be unable to supply the demand during the winter.

Dartford.—The District Council has appointed a Special Committee to deal with the electric lighting question.

Edinburgh.—After referring the matter back to the Lighting Committee, the Council has now adopted the recommendation to light certain streets by means of arc lamps. The salary of the resident electrical engineer has been raised from £500 to £600.

Fermoy.—The Town Commissioners have resolved that the agreement with Mr. Haynes Reed with reference to the electric lighting scheme for the township shall be signed without further delay, so that the lighting may be introduced before next autumn.

Fulham.—A special meeting of the Vestry, held on Wednesday last week, decided to carry out the provisional order and proceed with the erection of an electric lighting station, a dust destructor and disinfector. The cost of the scheme is estimated at £56,000.

Glasgow.—The Corporation has agreed to supply current to the Clyde Trustees for the lighting of the Queen's Dock and Prince's Dock at 2d. per unit, the trustees to provide all the necessary lamps and carbons for same, and to undertake the trimming of the lamps. Negotiations are to be opened with the Glasgow Harbour Tunnel Company, Limited, for obtaining a wayleave for laying and maintaining one or more electric cables therein.

Greenock.—The application of the North British Electricity Supply Company to the Board of Trade for a provisional order to supply electric lighting to Greenock, Port Glasgow, and Gourock has been meanwhile declined by the Board. Representatives from the three towns and of the company interviewed the Board of Trade on Friday last, and Sir Courtenay Boyle said that in the event of the Greenock Corporation not taking advantage of their provisional order for the supply of electric light to the town and district within a year, the application of the company would be favourably considered.

Hackney.—Deputations appeared before the Vestry on Wednesday, both in favour and against the disposal of the electric lighting order to a company. No conclusion was come to, however, for the matter was referred to the joint committee. It appeared from the proceedings that Mr. Medhurst has served a writ on the Vestry. A special committee has been appointed to deal with the matter.

Hampstead.—The Lighting Committee received a report from the chief electrical engineer explaining the advantage of adopting the use of demand indicators on the premises of all consumers of electric current, and recommended that demand indicators be fixed on all consumers' premises, present and future, in order that the charge for current supplied may be uniform throughout. Mr. Cottam stated that the indicators would cost about £2 each. The total outlay would be nearly £1,600. The recommendation was defeated by 18 votes against 15.

High Wycombe.—The Electric Lighting Committee, after having an interview with Mr. Bastian (on behalf of Messrs. Hodges & Todd, the electrical engineers appointed by the Corporation), and also with Mr. Wigham (engineer on behalf of Edmondson's Electricity Corporation, who are constructing the works for the Wycombe Borough Electric Light and Power Company), have made various recommendations to the Council regarding the general details of the undertaking, and these have been adopted. The positions for the arc lamps for street lighting are to be settled later.

Huddersfield.—The Electric Lighting Committee reports that the number of consumers this month is 650, an increase of 18 compared with March. The lamps connected during April are 44,047, an increase of 752, compared with the previous month.

Kimberley.—According to the last advices, a private Bill is to be introduced during the next Session of Parliament to empower the Borough Council of Kimberley to supply electricity for the purpose of lighting, heating, or furnishing power to public buildings and other places, and to borrow a sum of £25,000 for this purpose.

Leyton.—On 20th inst. a Local Government Board inquiry was held into the District Council's application for sanction to borrow £15,000 for electric lighting purposes. Mr. Bishop, the electrical engineer, explained matters. There are at present 6,780 lamps (public and private), 29 being arcs, and 500 or 600 lamps waiting for connection.

Longton.—The Corporation of Longton, who have resolved to take up the question of municipal electricity supply, have retained Mr. Robert Hammond as their consulting electrical engineer to lay a scheme before them.

Loughborough.—The General Purposes Committee has resolved, upon the Gas and Electric Lighting Sub-committee's recommendation, to apply for an electric light provisional order, and to spend £50 for professional assistance for the purpose of the proposed application. The matter will come before the Council.

Lowestoft.—The General Purposes Committee of the Town Council considered last week the alterations made by the Board of Trade in the electric light provisional order.

Lyndhurst.—Before committing themselves to the electric light, the Parish Council want to know terms. A letter from an electric lighting company has been before the Council.

Maidstone.—The Maidstone Town Council have resolved by eleven votes to six to defer the matter of the electric light until the result of the first year's operation of the Shoreditch electric light and dust destructor scheme has been ascertained.

Manchester.—We briefly mentioned in a "Note" last week the estimated surplus of the Corporation electricity undertaking for the ensuing year. We now give the exact figures as stated by Alderman Higginbottom at last week's meeting of the Electricity Committee. The estimated expenditure on revenue account is £53,829. The leading items are: coals, £7,700; oil, waste, water, &c., and current used on works, £4,300; repairs and maintenance, renewals of plant (transfer), £9,000; interest on mortgage debt, &c., £9,700; and sinking fund, £10,328. The estimated income, by sale of current and meter rentals (including £1,500 receivable from the city fund for public lighting) is £66,000, leaving a profit balance of £12,171, out of which it is anticipated that £12,000 will be devoted to the relief of the rates. Last year the estimated income was £55,000, and the actual income £57,800, which yielded a surplus of £14,080. The estimate of expenditure on capital account for the year ending March 31st, 1899, is as follows: land (sub-stations), £6,900; buildings (sub-stations), £5,000; buildings and foundations (Dickinson Street), £5,000; machinery, £59,000; mains, £60,000; meters, £3,000; cable stores and workshops, £5,000; total, £143,900. The estimate of expenditure on street lighting for the same period is: current for public lighting, £1,500; lamps and connections, £5,500; making the amount required to be raised in the current year's rate £7,000.

At an adjourned meeting of the City Council on 20th inst., with the consent of the Council, Mr. Alderman Higginbottom was permitted to introduce, out of the ordinary course, the recommendation of the Electricity Committee to make application to the Local Government Board for their sanction to the borrowing of the further sum of £150,000 for the purposes of the electricity undertaking of the Corporation. In moving the adoption of a resolution approving the Committee's recommendation, Mr. Higginbottom said the money was required for electricity purposes in the city, Moss Side, Levenshulme, and Withington, under orders which had been sanctioned by Parliament. In Manchester it was needed to provide (1) six new feeders to supply the old network. These would be necessary to convey the current from the new generators to the distributing mains. (2) Distributing mains in Chester Road and City Road. These mains it had already been determined by the Committee to lay forthwith. In addition to these, it would be desirable to connect up with Moss Side along Denmark Road and Moss Lane, and also along Preston Street. Borrowing powers would also be required for the erection of cable stores and a testing room on the land at the Polygon, and for purchasing sites for transformer sub-stations in various parts of the city. The high pressure feeders would be necessary for supplying some of these sub-stations, and also the sub-stations in Moss Side and Levenshulme. Provision was also made for carrying out the street lighting which it had been decided to provide for winter. There had likewise been included a sum for new services and meters in the city area. In regard to Moss Side, the money was required for the distributing mains in the compulsory streets and for the high pressure mains. At Levenshulme the money was required for a site for a transformer sub-station, for distributing mains in the compulsory streets, and for high pressure feeders. At Withington the money was required for sites for transformer sub-stations, for distributing mains in the compulsory streets, and for high pressure feeders. The following was a summary of the estimated cost:—Manchester, £73,300; Moss Side, £15,600; Levenshulme, £8,970; Withington, £48,920; total, £146,790. This would leave a sum of £3,210 for "sundries and contingencies." Sir John Harwood suggested that the sum asked for should be £200,000, and moved an amendment accordingly. This was seconded by Mr. W. Pollitt, and the Council agreed to it.

Metropolitan Asylums Board.—At the meeting on Saturday the Works Committee submitted a report in regard to the proposed electric lighting of the Northern Hospital. The Committee stated that Messrs. Burstall & Monkhouse, the consulting engineers, had informed them that in view of the great rush in the engineering trade, and in order that the engines and dynamos, as well as the boilers required for the electric lighting, might be delivered before next winter, it would be desirable to issue the specification for these works in advance of the specification of the wiring and other electrical work. The consulting engineers suggested further that, from the nature of the work, it was desirable to obtain tenders from a limited number of approved firms, rather than by advertisement. The Works Committee therefore recommended, and it was decided to apply to the Local Government Board for assent to obtain tenders for the engines, dynamos, and boilers for the electric lighting of the Northern Hospital in the manner suggested by the engineers.

Messrs. Handcock & Dykes, of Westminster, S.W., have been appointed consulting electrical engineers in connection with the electric lighting of the Tooting Bec Asylum.

The Brook Hospital Committee reported having consulted Prof. Kennedy, who designed the installation at that hospital, in regard to the maintenance of the storage battery. The Committee suggested that an agreement should be entered into for the maintenance of the battery for three years, but by the consent of the Board the recommendation was withdrawn for the time being.

Newmarket.—The Council does not approve of the site suggested by the electric light company.

Norwich.—A local paper says that the construction of the tramway track is now being proceeded with.

Peterborough.—Official intimation has been received by the Town Clerk that the Local Government Board has, upon further consideration, agreed to sanction the Peterborough Corporation borrowing a loan of £15,000 for electric lighting.

Plymouth.—The foundation stone of the Corporation electricity works was laid by the Mayor (Alderman J. T. Bond) on 21st inst. Mr. A. R. Debnam, chairman of the Electric Lighting Committee, explained the extent to which it was at first intended to provide current for lighting and traction purposes.

Portsmouth.—Last Saturday a visit was paid to Portsmouth by Mr. Gilbert, the president of the Boston Electric Light Company (U.S.A), and Mr. Hosman, the engineer and secretary to the company. They are stated to be making a tour of Europe to discover the best system of electric street lighting, in order that it may be introduced into Boston, which already boasts the largest plant in the world, the street arc lamps there numbering no less than 2,800. Mr. Gilbert is reported to have declared that though he had been all over the Continent, he had never seen so good a system of arc lighting as there is at Portsmouth.

Ripley.—A petition is being signed in Ripley in favour of electric lighting.

Shanklin.—The Shanklin Trade Union had a discussion on electricity v. gas a few days ago.

Sheffield.—A public meeting of the owners and ratepayers of the city was held on Tuesday to consider the Council's proposal to promote a Bill for the purchase of the electric light undertaking and raising money for the purpose. The proposal was not approved by a majority of those present, and a poll is to be taken in May, the result to be declared on May 25th. A Sheffield paper implies that the meeting was attended by a number of electrical traders who were afraid that the Corporation might take away their wiring and fitting business, and they seem to have been responsible for the voting.

Southampton.—At the last meeting of the Harbour Board, the Works Committee reported that the electrical engineer (Mr. J. G. W. Aldridge) had submitted plans of the necessary electric mains for the new cranes at the Quay, estimated to cost about £350. He stated that the cable could be purchased of the makers and laid by the Board's staff. The Board accepted the Committee's recommendation to adopt the plan of the electrical engineer.

St. Pancras.—The profit on the last year's working of the electricity undertaking has sufficed not only to wipe out a deficit of £800 on the previous year's accounts, but to provide a balance in hand of £5,717.

Swansea.—At a special meeting of the Corporation on Friday a report of the sub-committee was received showing that they had failed to arrange with the British Electric Traction Company to supply the latter with electricity for the trams at 1½d. per unit up to 400,000 units, and 1¼d. per unit for any subsequent amount per annum. The company explained that it was undesirable that the tramway power should be secondary to the lighting, and continuity of supply was imperative. The company also could not pay any more than the actual cost of production, and therefore would provide their own works. The sub-committee advised the immediate proceeding with the Corporation's own scheme, in combination with a dust destructor, as it was most necessary to have the station in their own hands. Mr. Manville, the electrical engineer engaged, attended, and after a long discussion it was decided, with only two dissentients, to proceed with the scheme, and to borrow £60,000 for the purpose.

Taunton.—The Council last week adopted a recommendation of the Electric Lighting Committee that the sum of £11,500, instead of £10,000, as previously agreed upon, should be applied for in order to provide for renewal of plant. Messrs. Kincaid, Waller & Manville, electrical engineers, of Westminster, presented a long report, which was explained by Mr. Manville, who attended the meeting. He said the electric light installation in Taunton was one of the first in the Kingdom for public lighting purposes, and they necessarily had to start with plant which was usual in those days, and in fact the only plant that could be obtained, and in the extensions made by the Bill since they took the works over from the old company they had proceeded on the lines originally laid down. Those lines did not involve the greatest amount of efficiency in the running of the station, and his firm were anxious that the whole system should be brought up from the present somewhat antique design to the most modern lines, so that the station might be as efficient as any existing. If his recommendations were carried out a gross saving of £539 a year would be effected on the basis of the present output, and there would be a net saving of £373 a year after providing for payment of capital and interest on the money required for the proposed alterations. The report was adopted.

Tipton.—The District Council on Tuesday heard representatives of the Midland Electric Corporation, and, after discussion, resolved to withdraw the opposition to the scheme.

West Ham.—Last Friday a Local Government Board inquiry was held with respect to an application by the Town Council for sanction to borrow £2,841 for the purpose of lighting the public buildings in the borough by electricity.

Wolverhampton.—Public notice is being given, signed by Mr. Harman Lewis, the borough electrical engineer, to the effect that on or about 28th inst. (yesterday), the supply of electric energy is to be commenced at a standard pressure of 220 volts, from Albany Road, on the north side of Darlington Street, on both sides of Chapel Ash, Tettenhall Road to the Clevelands, Compton Road to Chapel Terrace, and Merridale Road to Oaks Crescent.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Bristol.—The chairman and vice-chairman of the Bristol Sanitary Committee (Alderman Cope Proctor and Mr. G. Pearson) having talked over questions of electric traction still in dispute with the representatives of the Bristol Tramways Company, reported to their committee the result of their negotiations and made certain recommendations as to the course to be taken. A draft report to the Council was drawn up and this was dealt with and revised at another meeting of the Committee held on Monday It will be presented to a meeting of the City Council on Friday. It shows that there have been concessions on both sides, but there are still terms remaining unsettled. One point upon which the company has agreed is that of the capital required for works not less than £200,000 is to be raised in such a way that the rate of interest thereon shall not exceed 4 per cent. They are also willing that the fares shall be reduced so as to average ¾d. per mile for ordinary passengers, and ½d. per mile for workpeople's cars, the times for running which are to be extended. The controversy over the period at the end of which the Corporation shall be permitted to purchase resulted in 17 years from May, 1896, being agreed upon. The draft report set forth that the company should not be required to pay a wayleave for the permission to use electric traction, but this the Committee at their second meeting altered, and the report advises the Council that no arrangement would be satisfactory which does not require the company to pay a moderate wayleave, that there should be a further reduction of fares, and that the Corporation shall have the right to veto the overhead system in certain limited areas of the city.

Bournemouth.—The British Electric Traction Company and the Bournemouth, Poole and District Light Railway Company having informed the Council that they propose amended schemes, the Council has resolved that it is still undesirable that tramways should be laid down in the borough, and that steps are to be taken to prevent powers being granted.

Buenos Ayres.—The chairman of the City of Buenos Ayres Tramways Company, Limited, addressing the shareholders last week in London said that the question of the adoption of electric traction instead of horse-power had been fully considered by the board and by the local committee and general manager. They had received a report from the local committee regarding the possible advantages and disadvantages of the adoption of electric traction. That report was handed to an eminent firm of experts, who arrived at the same conclusion as the local committee—namely, that the substitution of electricity for horse-power was not desirable either in the interest of the public or of the company. After serious consideration of the whole question, the board had come to the decision that although the electric motor system might possibly be adopted with advantage to suburban traffic, it was absolutely unsuitable to the narrow streets in which their lines were laid.

City and South London Railway.—Lord Morley's Committee of the House of Lords has passed the City and South London Railway Bill, which confers extension powers. The company is also to raise £133,000 additional share and loan capital. The powers originally sought for the purpose of selling a portion of the undertaking to the City and Brixton Company have been struck out of the Bill.

Dundee-Barnhill.—A private meeting of the Broughty Ferry Police Commission was held last week at which representatives of a Leeds firm submitted plans of a proposed electric railway between Dundee and Barnhill. The system proposed is of the overhead trolley type, and the proposed route will be from High Street, Dundee, thence along Seagate, Blackscroft, and Ferry Road, crossing the railway at the Oil Mills, and onwards to Broughty Ferry, along Queen Street, Monifieth Road, to Barnhill. The Broughty Commission is stated to have agreed to support the scheme. Official notice of the scheme, published in a Dundee paper, is signed by the solicitors and Parliamentary agents, and also by Messrs. Greenwood and Batley, Limited, Albion Works, Leeds, promoters; Mr. Robert Ord Ritchie, M.I.E.E., Albion Works, Leeds, electrical engineer; and Messrs George Hopkins & Sons, 30, Parliament Street, Westminster, S.W., civil engineers.

Ealing.—The old District Council pledged itself to strenuously oppose the scheme of the London United Tramways Company, but now that there is a new council in office, eight of its members being in favour of electric traction, there seems to be some prospect of the matter receiving careful reconsideration. Notice of motion has been given for the question to be discussed at the next Council meeting.

Hastings.—On 20th inst. the Town Council held a special meeting to discuss the tramways question, and a resolution was passed by 24 votes to 14 applying to the Light Railways Commissioners for an order authorising the Council to construct and work light railways in various parts of the borough.

Hungary.—According to recently published statistics, the total length of street railways in Hungary at the end of 1897 was 115 miles, of which 64 miles were worked by electricity. In the past year the introduction of electric traction on the street railways of Buda-Pesth was completed, and, besides two new railways worked by electricity were opened, namely, the "Miskolezer electric street railway," and the "Maria Theresiopoler electric railway." The traffic on some of the Buda-Pesth electric railways show a considerable falling off in 1897 when compared with 1896; a result which is ascribed to the Millenial Exhibition in the latter year.

Malaga.—It is proposed to convert the horse tramways in the town of Malaga, Spain, into electric lines.

Moscow.—The April *Board of Trade Journal* has some interesting notes regarding the proposed electric tramway schemes for Moscow. It seems, according to H.M. Consul at that town, that the municipal authorities of that city purpose converting the present horse tramways of Moscow into electric tramways. The two tramway companies of Moscow have placed themselves in communication with two financial syndicates in Berlin and Dresden, and certain propositions have been made to the Mayor of the town—Prince Galitzin—who has referred the whole business to a special commission to draw up a report and furnish H.M. Consul with a statement of what is actually required. This document will not be ready for some months, but should the Mayor eventually receive tenders from British firms, he promises that the same will have careful attention from the Commission and exactly the same chance of being accepted as the tenders from other countries.

Richmond.—On Friday night a meeting of the Richmond Town Council was held, when objection was made to the scheme of the London United Tramways Company for an electric tramway to traverse Richmond—by a "back road" route—and Kingston to Hampton Court.

Rochester.—Last Friday an inquiry by the Light Railways Commissioners with reference to the application by a private company to establish a system of electric trams connecting New Brompton, Chatham, Rochester, Strood, and district, opened at Chatham. The two Town Councils and the Urban District Council of Gillingham are in favour of the project.

St. Helens.—Major Cardew, R.E., has been holding a Board of Trade inquiry into the application by the St. Helens Corporation for sanction to use electrical power on local tramways on the overhead system, and to the borrowing of £25,000 for purposes connected with the adaption of the line, &c., to electrical traction.

Switzerland.—The three-phase electric railway which is being built near Zermatt on the Gorner Grat was recently tested for the first time, in presence of the Swiss inspector of railways. The section just finished has a length of 1,600 m. and a gradient of 12 in 100. The experiments were very successful; the up and down journeys on the gradient were performed without difficulty; the full speed of the locomotives being maintained by the motors. The descent on the steepest part of the gradient was carried out with ease, with a fully load train. The new rack railway has a length of 9·8 km., and a maximum gradient of 20 in a 100. The power is taken from the Findelenbach, which drives four turbines of 250 H.P. each, coupled directly with three-phase dynamos of 5,000 volts and 40 periods per second. The voltage in the trolley wire is 550. Every locomotive carries two three-phase motors of 90 H.P. each, which are geared to the driving wheels by toothed gearing. The three-phase motors act as generators, and require as much power to drive them as they give out; if in the descent they are driven 2 to 8 per cent. above the speed of synchronism, the locomotive gives back power to the leads. When all the locomotives on the line are descending, the excess power given back is absorbed in a water resistance in the power station. The electric part of the installation has been carried out by Brown, Boveri & Co., and is on the system which this firm has used on the Lugano line. They have also applied the same system to the Jungfrau Railway, and are at present applying it to the line from Stanstaad to Engelsburg, which will be opened this year. The line from Burgdorf to Thun, in the canton of Berne, will also be built on the three-phase system by this same firm.

TELEGRAPH AND TELEPHONE NOTES.

Cape Town to Blantyre Telegraphs.—Mr. Cecil Rhodes received the following letter on 21st inst. from the Postmaster-General at Cape Town:—"Through telegraphic communication from Cape Town to Blantyre (British Central Africa Protectorate) was established yesterday (Wednesday). Congratulations." The distance between the two points exceeds 2,000 miles.

Communication with the Cape.—We learn from the *Cape Argus* of the 23rd ult., that during the period when the West Coast route was interrupted last month, at the same time that the Delagoa Bay-Natal cable was interrupted on the East Coast, messages from the Cape to London had to pass *viâ* the Transvaal. It can hardly be pleasant reading for many of the merchants, and others connected with the Cape, to know that they have to thank the South African Republic for affording them at that time the only means of transmitting their telegrams.

The Delays in Australian Telegrams.—In our various notices concerning the delays and interruptions to Australian trunk landlines, we find we omitted to mention that on Feburary 23rd last, "West Australian section: Owing to the presence of a hurricane between Israelite Bay and Eucla, that section of coastal line worked only simplex very badly; inland line also affected by heavy weather between Balladonia and Eucla, which prevented quadruplex working on this wire, fair duplex circuit available; our inward business suffered delay. South Australian section: Both lines worked duplex well till 10 p.m., when reduced to simplex; the new line worked badly, and the old wire fairly well till clear. Outward clear by West Australia 11.35 p.m. Outward clear by South Australia 2.30 a.m." From this it is clear that as regards the inefficiency of the South Australian, as compared with the West Australian landlines, there is little or nothing to choose; both appearing to be equally infirm; and yet it has been suggested that such lines as these should form a portion of the cable system which it was proposed to extend from London to Australia *viâ* the Cape of Good Hope.

A Pacific Cable.—An American exchange says that late advices from Honolulu announce that the Hawaiian Legislature is considering a Bill authorising the construction by the Pacific Cable Company of a cable between the United States and the islands. The Hawaiian Bill gives the company exclusive cable rights for 20 years. The cable must be laid within 18 months after the passage of the Act by the American Congress, and extended to Japan within three years. It must be capable of transmitting 15 words a minute, and the toll rate between Honolulu and San Francisco is not to exceed 35 cents a word, and to Japan it is not to exceed 90 cents a word.

Queensland and the Pacific Cable.—In a speech made last week at Brisbane by the Hon. T. J. Byrnes, the new Premier of Queensland, as to the past and future policy of the Government of that Colony, amongst other statements the speaker said: "He was thoroughly favourable to the Pacific cable, and the Government were prepared to take a strong lead in the matter." This is quite in accordance with the conclusions arrived at by the majority of the Premiers of the various Colonies at the recent conference held in Melbourne, where "It was resolved that if Great Britain and Canada each contributed one-third of the cost of the Pacific cable, New South Wales, Victoria, Queensland, and Tasmania would be in favour of contributing the remaining third. Mr. C. C. Kingston (South Australia) and Sir John Forrest (Western Australia) dissented from the resolution, expressing preference for the cable route *viâ* the Cape of Good Hope." The dissentient vote of the two latter is, of course, easily understood, as it is in the interest of the colonies which they represent to retain as long as possible control of European traffic, which at present passes over the landlines of South Australia and Western Australia; but it seems that, in view of the great frequency of interruptions to both lines, these gentlemen would have advanced the interests of Australia as a whole by voting with the majority.

Telegraphic Interruptions and Repairs:—

The name of the company should be *Bermudas*, not Bermuda.

West African Telegraphs.—A Reuter despatch, dated Lagos, April 25th, says that telegraphic communication has been established between Lagos and the British post of Jebba, situated on the Niger a little north of the ninth parallel. The whole of the work through the Ilorin State has been successfully carried out on the Lagos side by Captain Turner, R.E., and Mr. Stone, of the Lagos Public Works Department.

CONTRACTS OPEN AND CLOSED.

OPEN.

Aberdeen—The Council invites tenders for the supply and laying of about 10 miles of ·67 single core feeder cable, 5 miles of ·2 three-core network cable, and 3⅜ miles of arc lamp series cable. The cable is to be armoured and laid in wooden casing. Under another contract the Harbour Commissioners invite tenders for the supply and erection of 62 arc lamps and three leading lights, each consisting of four arc lamps. All lamps to be Brockie-Pell or Crompton-Pochin. Both the contracts will have to be completed by August 31st, and particulars in both cases can be obtained from the Corporation Electricity Works, Cotton Street. See our "Official Notices" April 22nd.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Edinburgh.—May 6th. The Corporation wants tenders for the wiring of the St. Leonard's police station. Particulars from the resident electrical engineer, 5, Dewar Place, and see our "Official Notices" this week.

France.—May 5th. The French Post and Telegraph Authorities in Paris are inviting tenders until May 5th for the supply of about 139 kilometres of electric cables (gutta-percha insulated). Particulars may be obtained from, and tenders to be sent to, Le Sous-Secretariat d'Etat des Postes et des Telegraphes, Rue de Grenelle, Paris.

Great Eastern Railway.—May 12th. The directors invite tenders for the supply of stores and materials. For particulars see our "Official Notices" this week. Forms of application from the secretary's office, Liverpool Street Terminus, E.C.

Hyde.—May 5th. A Corporation Committee invites tenders for the supply and fixing of gas engine, dynamo, wires, fittings, &c., for electric lighting at the new technical school and free library. Engineers, Messrs. Lacey, Clirehugh & Sillar, 78, King Street, Manchester. See our "Official Notices" April 22nd for particulars.

London.—May 17th. The Bethnal Green Board of Guardians invites tenders for the supply of plant, and installing the electric light at the new infirmary, Palestine Place. Plans, &c., to be obtained from the architects, Giles, Gough & Trollope, 28, Craven Street, Charing Cross, W.C. See our "Official Notices" April 22nd for particulars.

Roumania.—April 30th. Tenders are being invited until the 30th inst. by the Roumanian Post and Telegraph Authorities in Bucharest, for the supply of 50 tons of galvanised iron wire, 10 tons of galvanised steel wire, and 5 tons of tinned copper wire. Particulars may be obtained from, and tenders to be sent to, La Direction Générale des Postes et Telegraphes, Bucharest, Roumania.

Sunderland.—April 29th. The Corporation is inviting tenders for the supply of a high-speed 225-kw. steam dynamo, and two Lancashire or Galloway boilers. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" April 15th for particulars.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

West Ham.—May 10th. The Council wants tenders for certain electroliers, standards, &c., required for its public buildings. Mr. J. J. Steinitz, borough electrical engineer. See our "Official Notices" this week for particulars.

CLOSED.

Bournemouth.—The following is a list of the tenders sent in for supplying and fixing cables, conductors, lamps, columns, fittings, &c., for the lighting of the Bournemouth Pier and Lower Pleasure Grounds by electricity. F. W. Lacey, M.Inst.C.E., borough engineer and surveyor, can perhaps inform us how the enormous differences originate:—

——	Pier installation.			Pleasure grounds installation.			Arc lamps for pier and square.			Total.		
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
Crompton & Co., Limited ..	2,900	0	0	1,780	0	0	524	0	0	5,204	0	0
Johnson & Phillips	1,353	6	0	1,386	12	0	66	0	0	2,805	18	0
Brush Electrical Engineering Company	816	17	6	702	0	0	221	2	6	1,740	0	0
Laing, Wharton & Down, Limited	786	0	0	694	0	0	227	0	0	1,707	0	0
Leonard G. Tate	825	0	0	507	0	0	270	0	0	1,602	0	0
British Insulated Wire Company, Limited	725	4	7	582	0	2	326	10	0	1,583	14	9
Bournemouth and District Electric Supply Company	576	17	8	485	2	8	352	19	8	1,415	0	0
Cash, Robinson & Co. ..	588	3	0	472	0	0	192	14	0	1,252	17	0

The following were informal:—Scott, Anderson & Beit, R. Whipp & Co., Bow, McLachlan & Co., Mendham & Co., Lovell-Simons & Co., Fippard & Cooper, E. G. Bryant.

Leyton.—We understand that the Council has accepted the tender of Messrs. Siemens Bros. & Co. for the supply of dynamos at £737, that of Messrs. Wells Bros. for gas engines (£1,708) and that of Messrs. Laurence Scott & Co. for switchboards at £150. The buildings contract is in the hands of Mr. Coxhead. We gave particulars of the tenders last week.

Newcastle.—The Lunatic Asylum Visiting Committee of the Newcastle Corporation has considered the tenders for the installation of the electric plant for the lighting of the new extension at the asylum, and that of Messrs. Corlett & Company (£2,388) has been accepted.

Watford.—We understand that Mr. Henry J. Rogers, Watford, has received instructions to supply all the arc lamp columns and arc lamps for the Watford electric lighting scheme.

FORTHCOMING EVENTS.

1898.

Saturday, April 30th.—Association of Municipal and County Engineers at Wimbledon, 11.15 a.m. Paper by Mr. A. H. Preece, electrical engineer to the Wimbledon Council, on "The Works to be carried out for the Supply of Electrical Energy to the District"; at 4.15 p.m. the members will inspect the Conduit and Insulation Company's works at Summers Town, and a paper will be read by Mr. F. H. Bathurst on "Electric Wiring Practice."

Monday, May 2nd, at 8 o'clock.—Society of Arts. The first of a series of four Cantor lectures on "Electric Traction," by Prof. Carus Wilson.

Thursday, May 5th, at 8 p.m.—Chemical Society. Papers to be read:—"The Reactions of the Carbohydrates with Hydrogen Peroxide," by C. F. Cross, E. J. Bevan and Claud Smith; "The Properties and Relationships of Di-hydroxytartaric Acid," Part II., by H. J. H. Fenton, M.A.; "The Affinity Constants of Certain Hydroxy-Acids," by S. Skinner, M.A.; "Molecular Weights in Solution of Permanganates, Perchlorates and Periodates," by J. Murray Crofts, B.A., B.Sc.

Extra meeting of the Institution of Electrical Engineers, to be held at the Society of Arts, to hear a paper by Mr. Leonard Andrews, A.I.E.E., on "The Prevention of Interruptions to Electricity Supply." This arrangement was subject to the discussion on Messrs. Parshall, Cardew and Trotter's papers finishing last night.

Friday, May 6th, at 8 p.m.—The Institution of Junior Engineers at the Westminster Palace Hotel. Paper to be read and discussed:—"Evaporative Condensers and Independent Air-pumps for Same," by Mr. Harry Fraser (member).

Monday, May 9th, at 8 o'clock.—Northern Society of Electrical Engineers at Manchester. Paper by Mr. W. C. C. Hawtayne.

Friday, May 13th, at 5 p.m.—Physical Society. Paper on "Galvanometers," Part II. By Prof. W. E. Ayrton and Mr. T. Mather.

NOTES.

Institution of Civil Engineers.—At the annual general meeting of the Institution of Civil Engineers, held on April 26th, Sir John Wolfe Barry, K.C.B., president in the chair, the result of the ballot for the election of officers was declared as follows:—President, Mr. W. H. Preece, C.B.; vice-presidents, Sir Douglas Fox, Mr. James Mansergh, Sir William Anderson, K.C.B., and Sir William White, K.C.B.; other members of council:—Mr. James Barton (Dundalk), Mr. Horace Bell, Sir Alexander Binnie, Mr. Thomas Forster Brown (Cardiff), Mr. Henry Deane (Sydney), Mr. W. R. Galbraith, Mr. George Graham (Glasgow), Mr. J. C. Hawkshaw, Mr. Charles Hawksley, Mr. G. H. Hill (Manchester), Dr. Hopkinson, Mr. J. C. Inglis, Mr. Alexander Izat (India), Dr. Alex. B. W. Kennedy, Mr. John Kennedy (Montreal), Sir James Kitson, Bart., M.P. (Leeds), Mr. A. G. Lyster (Liverpool), Mr. William Matthews, Sir Guilford Molesworth, K.C.I.E., Sir Andrew Noble, K.C.B. (Newcastle-on-Tyne), Mr. Alexander Siemens, Mr. Thomas Stewart (Cape Town), Mr. F. W. Webb (Crewe), and Sir Leader Williams (Manchester).

Institution of Electrical Engineers.—Before this Institution last night papers were read on "Earth Returns for Electric Tramways," by H. F. Parshall, member; and "Notes on Electric Tramways," by Major P. Cardew, R.E., and A. P. Trotter, members.

Cables in War Time.—In the House of Commons on Tuesday Mr. Nussey (Pontefract) asked the First Lord of the Treasury whether he could inform the House if either belligerent had the right, and if so to what extent, to interfere with cables between the territory of the opposing power and any other part of the world. Mr. Balfour in reply said: "A convention, to which Great Britain, Spain, and the United States were parties, was concluded at Paris on March 14th, 1884, providing for the protection of submarine cables. But by Article XV. thereof in time of war a belligerent signatory to the convention is free to act with respect to submarine cables as if the convention did not exist. I am not prepared, therefore, to say that a belligerent, on the ground of military exigency, would, under no circumstances, be justified in interfering with cables between the territory of the opposing power and any other part of the world."

The *Times* concludes a leader on the war by some remarks on the fate of the cables. The article says:—

Messrs. Eyre & Spottiswoode write to us to-day quoting a decision that they are commercial property, not liable to seizure, or at least to destruction, even if they carry war messages among others. But Mr. Balfour last night, in reply to a question, quoted a convention to which England, Spain, and the United States were parties, providing for the protection of submarine cables, yet reserving to a belligerent the right to treat them as if the convention did not exist. It seems, therefore, to be an open question what is the precise position of submarine cables under existing usages, though there can be none as to the position that ought to be assigned to them in conformity with the spirit of the Declaration of Paris. As the Power which can cut them can generally tap them and stop all messages injurious to its interests, there seems the less reason for exempting this form of neutral property from the protection of the neutral flag.

A telegram published early in the week in the *New York Herald* from its special correspondent at Key West says:—"The United States lighthouse tender *Mangrove* has picked up the cable between Havana and Key West. All the despatches passing over the cable to or from the Cuban capital are being read. The Government now has its own operators in Key West and a cable office. All despatches are subjected to censorship."

The Postmaster-General on Tuesday notified that telegrams for all places in Cuba by the North American cables, *via* Key West, must be handed in at telegraph offices under the control of the British Post Office, written in plain language, and will be accepted only at the sender's risk.

The Physical Society.—Before this Society on Friday last, Dr. S. P. Thompson exhibited a model apparatus made by the Helios Company, to illustrate the three-phase method of transmitting power. It consists of a small generator, driven by hand, and a small motor. The generator is separately excited by a small secondary battery; it has three independent coils. The six ends of the coils are connected to six commutator rings. The motor has three corresponding pairs of opposite coils; these can be grouped in various ways for connection to the brushes of the generator. The six coils are on a hinged frame, so that, if necessary, they can be laid down flat for other rotation experiments. Two armatures are provided, either of which may be used. The first is an iron wheel, with peripheral copper bars arranged like a squirrel-cage; the other is a simple iron disc, without added conductors.

Electric Wiring at Buenos Ayres.—The editor of the *Review of the River Plate* recently inspected several electric lighting installations carried out for some private houses in Buenos Ayres by Messrs. Rufino Varela (hijo) & Co., and found that in nearly every instance the entire installations were being made without a single joint in the wires. This, says the writer, is certainly a move in the right direction, as joints, as a rule, are the initial cause of all trouble in these installations. In many cases they are either not soldered, or else the work is scamped; then they are badly insulated; very often the wire is burnt by careless workmen, and breaks whenever any strain is placed upon it. This jointless work has, in our contemporary's opinion, a great advantage over all others, as it does away with the primary cause of outbreaks of fires, keeps up the insulation resistance, and the special fittings used for branches are strong and neat, and the work easily lends itself to inspection and revision in case of faults.

Municipal Authorities and Electric Lighting.—On Monday a conference of municipal authorities of England and Scotland, convened by the Municipal Electrical Association, was held at the Westminster Palace Hotel, to ascertain their views as to what course should be taken before the Joint Committee of the two Houses of Parliament, which is now considering the question of electrical energy, generating stations, and supply within extensive areas, and has agreed to certain clauses. Manchester, Wolverhampton, and Glasgow had already agreed to take common action, and the representatives of the other municipalities on Monday agreed to support the course that they had decided to take before the Select Committee, and that their interests should be represented by Mr. Worsley-Taylor, Q.C., Mr. Pritchard, Q.C., and Mr. Lewis Coward. After debate, the conference unanimously decided that, notwithstanding the provisions of the Electric Lighting Act, 1882, powers should be given to municipalities for acquiring land compulsorily for generating stations, and that as to liability for nuisance and notices to owners, they should be under the same statutory powers as railway companies as to their liability for compensation or damages for neglect; that compulsory powers should be given for acquiring land for generating purposes not within the area of supply; that power should be given for breaking up streets between the generating station and the boundary of the area of supply; that powers should be given for the supply of electrical energy over an area including districts of numerous local authorities, with the consent of such authorities; and that powers ought to be conferred upon promoters seeking to supply electrical energy "to other undertakings, and not directly to consumers," with the consent of the local authorities.

Röntgen on the Röntgen Rays.—Such a host of investigators have devoted themselves to the development of Prof. Röntgen's great discovery, that it would be no matter for surprise if there was nothing left for the discoverer to find out about his own discovery. Some novel properties of the X rays, however, have been described by Prof. Röntgen in a third communication on this subject to the Berlin Academy. Among these the following appear to be especially interesting. If a fluorescent screen is covered with a plate completely opaque to the X rays, a slight fluorescence can nevertheless be seen when the tube is in action. Röntgen has shown that this is due to rays proceeding from the air of the room, which emits X rays wherever it is itself exposed to their action. This fact points to the necessity of placing photographic plates in a sheath of lead when used for long exposures, to prevent them being fogged by diffused rays from the back or sides. Of the rays which are given off by the platinum plate of a focus tube, those are most effective for producing pictures which leave the platinum at as great an angle as possible, within a limit of 80°. The specific transparency of bodies is greater the thicker the body. The ratio of the thicknesses of two equally transparent plates of different material is dependent on the thickness and the material of the medium through which the rays have to pass before they reach the plates. For instance, the ratio of the thickness of platinum and aluminium plates of equal transparency will be reduced to one-half if the rays are passed through a thick glass plate before they strike the metal plates. Röntgen, like Swinton and others, has shown that the contrast between bodies of different transparencies depends on the E.M.F. used to excite the tubes. A spark gap in the secondary circuit acts in the same way as an intercalated Tesla transformer; both produce more intense and less easily absorbed rays. By the use of a Tesla transformer and wire electrodes in a narrow tube, X rays can be produced with a vacuum of 3·1 mm., the usual vacuum being, of course, about 0·0002 mm. Hard tubes, as Röntgen calls those tubes which require a very high E.M.F., can be softened, as is well known, by heating, or by re-admission of air, or, as is not so well known, by heating limetree charcoal placed in a side tube, or by sending through the tube a very powerful discharge. The composition of the rays given off by the platinum anti-cathode depends essentially on the time change of the discharge current. The quality of the rays is not affected by the change of the primary current, but their intensity is proportional to the strength of the primary current.—*Elektro-Zeit.*, 19, p. 192.

Auxiliary Wastes.—The Chicago Electric Traction Company are now alive to the saving in substituting electric motors for steam in driving auxiliary plant. Their large engines developed 217 H.P. on a water consumption of 3,903, or at the rate of 18 lbs. per I.H.P.-hour. The small engines used steam as follows:—

Economiser engine	...	38·4 lbs. per hour.
Stoker engine ...	...	36·4 „
Air and feed pumps	...	685·0 „

The total is 759·8 lbs. per hour, or nearly 20 per cent. of the consumption of the main engines. While true that the exhaust went to heat the feed, the *Street Railway Review* says this was the function of the economiser, and it is scarcely an economy after all to employ a wasteful engine as a feed heater, when unavoidably wasted furnace products are available for the purpose.

Oil Fuel.—Oil fuel has been used for several weeks past at the Chicago Elevated Power Station, one of the 2,000-H.P. units having been run six hours daily on oil fuel. Storage tanks and pumps, with duplicate pipes, are completed.

Exhibition of Acetylene Apparatus.—The Executive Council of the Imperial Institute has on foot a scheme for holding an exhibition of acetylene gas generators and illumination by acetylene gas. The generators admissible are divided into three groups, viz., (1) those in which the gas is generated by water being allowed to drip, or flow in a small stream, on to the top of the carbide; (2) those in which water rises round the carbide; (3) those in which the carbide falls into the water; these being again sub-divided into automatic and non-automatic. Forms are being sent out for applications for space; but the Council will not undertake to hold the exhibition unless, by May 2nd, there is a sufficient number of applicants to cover the actual outlay which will be involved.

Street Lighting at Buenos Ayres.—The streets of the city of Buenos Ayres are at last to be lighted by electricity, as the municipality has accepted, says a River Plate exchange, the tender presented by the Compania General de Electricidad de la Ciudad de Buenos Ayres. To commence with, 300 8-ampere lamps are to be installed in various districts. The prices are:—120 lamps, burning all night, at $27 each, $3,240; 180 lamps, burning up to 1 a.m., at $20.25 m/n $3,645. Total, $6,885 per month. The saving under this arrangement as compared with the gas bill is expected to be considerable.

Electric Motor Printing Presses.—The *Electrical Age* says that the largest printing press ever built is being driven by a Crocker-Wheeler motor. This press was constructed by R. Hoe & Co., and is an octuple, stereotype perfecting press and folder. It prints, folds, counts and delivers 96,000 eight-page newspapers in an hour. A 75 horse-power motor built by the Crocker-Wheeler Electric Company, of Ampere, N.J., and New York, has been installed under the floor for direct connection to the gigantic press above it.

Steam Engine Trials.—At the South Western Polytechnic, Chelsea, S.W., a special class in "Steam Engine Trials," intended for draughtsmen and advanced engineering students, will be conducted by Prof. Pullen, Wh.Sc., A.M.I.C.E., and Mr. H. A. Clark, Wh.Sc., A.I.E.E., on Tuesday evenings, from 7.30 to 10 p.m., commencing May 17th and terminating June 28th, 1898. Inquiries to the head of the engineering department.

Gas Producer Feeding.—The importance of even feeding of gas producers is insisted upon by Mr. Bildt in a paper to the American Institute of Mining Engineers. The familiar hopper and cone introduces large masses of fuel suddenly into the producer, generating large volumes of gas at one time, while at another the gas becomes small in quantity and there will be excess of air with formation of carbonic acid, or when the gas is used in furnaces, oxidation of the metal from excess of oxygen. The cone is, moreover, an uneven distributor, depositing more fuel on one side than on another, and variable gas results. An ideal feeding device should be continuous in action, feeding just so much coal as will yield the gas required in a given time, and it should evenly distribute the coal over the surface of the already deposited fuel so as to give an even resistance to the rising column of air in order to prevent uneven action. The author has patented a device consisting of a spiral revolving in the upper part of the producer, and receiving coal through a shoot and slide. The description of the revolving spiral and its action is not very clear. Analyses are given of two gases, one from a producer using little water, the other from a steam-blown producer, which shows a large percentage of hydrogen and a very much smaller percentage of nitrogen. One is cited as from Domnarfoet, the other from the Washburn and Moen Manufacturing Company. They are as follows:—

	Domnarfoet	Washburn.
CO	2·00	4·90
O	0·10	*nil*
CO	27·90	26·80
C_2H_4	0·10	0·40
H	2·60	18·10
CH_4	...	3·50
N	67·60	46·30
	100·00	100·00
Percentage combustible	30·60	48·80

In the steam-blown furnace some of the CO has been made from oxygen produced by decomposing the steam jet. This, of course, saves using so much air, and reduces the nitrogen, thus producing a much richer and more combustible gas, as well as utilising the heat of conversion of carbon into monoxide to dissociate the steam. If the result is a cooler gas an economy will have been effected, but there is evidently a greater production of CO_2 with the steam jet, which, however, may not be due to this.

Presentation.—On Saturday last the staff of the King's Road Central Station, St. Pancras, presented a testimonial to Mr. H. R. Burnett (who is leaving the service to take up the position of borough electrical engineer at Barrow-in-Furness), consisting of a silver stop watch with suitable inscription. The presentation was made by Mr. Sydney W. Baynes (chief electrical engineer).

Lecture.—A lecture on "Wireless Telegraphy," with experimental illustrations, will be given on Wednesday, May 4th, at 8 p.m., also on Thursday, May 5th, at 8 p.m., at the Skinners' School for Girls, Stamford Hill, by Mr. J. E. Taylor. The proceeds are to be devoted to the Hackney Technical Institute movement.

The Spiral Globe, Limited.—We understand that within a few days the public will be asked to subscribe to the capital of a company with the above title. The spiral globe is a new form of lamp reflector, consisting of a closely-wound spiral of small glass rod around the bulb of the incandescent lamp. As a means of increasing the effective illuminating power of the lamp, it has been favourably reported upon by Mr. Hugh E. Harrison, Mr. W. H. Preece, and Mr. F. J. Down, the latter of whom ventures to estimate the company's probable sales at 2 million lamps per annum, and its profits at not less than £26,000.

Obituary.—We hear with regret of the death of Mr. George Greenwood, of the well-known firm of Greenwood and Batley, of Leeds, which occurred at his London residence on 16th inst. Mr. Greenwood was 57 years of age. Ten years ago, when the business was turned into a limited company, the deceased gentleman came to London and acted here as managing director. Mr. Greenwood was a member of various institutions, including the Institution of Civil Engineers.

Early Electrical Appliances.—We understand that by request of the secretary of the Institution of Civil Engineers, Mr. Killingworth Hedges, of Emery Hill Street, Ashley Gardens, Westminster, is gathering together, for the purpose of an exhibit at the May Conversazione, a representative collection of early electric lighting appliances used from about 1876 to 1886, excluding large objects, such as dynamos. This is, we understand, in honour of the new president, Mr. W. H. Preece, C.B., &c., and if successful, we believe the exhibit may take a permanent form. Mr. Hedges will be glad to receive exhibits, and to hear from all who are able and willing to render any assistance in this matter.

Davy Davies Hoisting Gear.—The Davy Electrica Construction Company write "to thank Mr. Ernest Kilburn Scott for his good opinion of the Davy Davies patent hoisting gear" in our last issue. "The gear, as illustrated," they say, "is merely one of our methods of carrying out the invention, and we see no difficulty in applying the gear to all kinds of street and private arc lighting."

NEW COMPANIES REGISTERED.

Lancashire Electrical Engineering Company, Limited (56,992).—Registered April 19th, with capital £5,000 in £1 shares, to acquire the business carried on by J. McDermott, J. E. Taylor, and W. Barratt at Volt Works, Old Street, Ashton-under-Lyne, as "The Lancashire Electrical Engineering Company," to adopt a certain agreement, and to carry on the business of electrical engineers, electricians, millwrights, &c. The subscribers (with one share each) are:—J. McDermott, Old Street, Ashton-under-Lyne, electrical engineer; J. E. Taylor, 40, Bentwick Street, Ashton-under-Lyne, electrical engineer; W. Barratt, 175, Old Street, Ashton-under-Lyne, electrical engineer; J. J. O'Connor, 28, Rycroft Street, Ashton-under-Lyne, electrician; J. Barratt, Trafalgar Street, Ashton-under-Lyne, engineer; W. Barratt, 132, Hyde Road, Gorton; C. Wilson, 27, Egerton Street, Higher Openshaw, pattern maker. The number of directors is not to be less than two nor more than three; the subscribers are to appoint the first; qualification, 50 shares. Registered office, Volt Works, Old Street, Ashton-under-Lyne.

Electric Horse Promotion Syndicate, Limited (56,996).—Registered April 19th, with capital £5,000 in £1 shares, to adopt an agreement with J. Lambert and to promote or assist in promoting a company for the acquisition of certain undescribed patents and inventions. The subscribers (with one share each) are: E. Kaiser, 131, Earl's Court Road, Kensington, clerk; A. J. Biss, 53, Elizabeth Street, Walworth, clerk; W. C. Ponsford, 6, Upper Tollington Road, N., clerk; H. Harman, 11, Charing Cross, S.W., clerk; L. Kelsey, 101, Victoria Road, Kilburn, theatrical manager; H. Lack-Szyrma, Barkingside, Ilford, solicitor; A. Trow, 46, De Beauvoir Road, N., accountant. Registered without articles of association by Chapronière & Co., 11, Charing Cross, S.W.

Lancashire Light Railways Company, Limited. (57,018).—Registered April 21st, with capital £50,000 in £1 shares, to construct, purchase, lease, contract for or otherwise acquire, equip, maintain, and work light railways and tramways in Lancashire or elsewhere, and to carry on the business of electricians, engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with one share each) are:—J. B. Atherton, Manhattan, Gateacre, Lancashire, manufacturer; F. J. Leslie, 15, Union Court, Liverpool, solicitor; W. M. M. Forwood, 15, Union Court, Liverpool, solicitor; C. O. Grindrod, 11, Knowsley Road, Rock Ferry, Cheshire, gentleman; A. E. Haptie, 5, Durham Road, Seaforth, Liverpool, cashier; A. Ruckley, 8, York Road, Seacombe, Cheshire, clerk; J. G. Setterfield, 16, Thorndale Road, Waterloo, clerk. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £200; remuneration as fixed by the company. Registered by F. J. Leslie and Company, 15, Union Court, Liverpool.

Sphere Lighting Company, Limited (57,040).—Registered April 22nd, with capital £12,000 in £1 shares, to adopt an agreement with F. Gallsworthy, to acquire any inventions, patents and rights, for the lighting of billiard tables and rooms by electricity or otherwise, and to carry on the business of billiard table and requisite manufacturers, electricians, electrical, mechanical, and metallurgical engineers, &c. The subscribers (with one share each) are:—F. Gallsworthy, 17, Wellington Street, Leeds, leather factor; J. Gordon, 1, Bond Street, Leeds, chartered accountant; J. M. Barwick, 24, Basinghall Street, Leeds, solicitor; A. C. Peake, 24, Basinghall Street, Leeds, solicitor; E. O. Simpson, 47, Albion Street, Leeds, solicitor; T. H. Cooper, Great Northern Hotel, Leeds, manager; G. H. Hebblethwaite, Westroyd, Mirfield, belt manufacturer. The number of directors is not to be less than three nor more than seven; the first are C. E. Bulling, F. Gallsworthy, J. Gordon, G. H. Hebblethwaite, A. C. Peake and E. O. Simpson; qualification, £100; remuneration as fixed by the company. Registered office, 47, Albion Street, Leeds.

CITY NOTES.

Huddersfield Corporation Electricity Works Accounts.

PROBABLY the best way of showing the sound and steady progress that is being made at the Huddersfield Municipal Electricity Works is to reproduce the comparative statement which is included in the abstract of accounts for the year ending December 31st, 1897. From a fairly heavy deficiency of £2,547, which was encountered at the end of the first year's work (1893), the management has been able to show a very substantial profit, after providing for interest and contribution to sinking fund.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£69,415	£58,117
Number of units sold	438,848	304,163
Number of lamps connected	41,702	28,983
Revenue from sale of current	£8,533	—
Net revenue	£4,964	—
Average price obtained per unit	4·66d.	—

Cost of production.	£		Per unit.	1896.
Coal	901		·49d.	—
Oil, waste, water, and engine room stores	104		·06d.	—
Salaries and wages at generating station	985		·54d.	—
Repairs and maintenance of buildings, ngines, boilers, dynamos, &c.	794	Works' cost 1 52d.	·43d.	—
Rent, rates and taxes	311		·17d.	—
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	1,001		·55d.	—
Depreciation of buildings and plant account	—		—	—
Renewal fund account	—		—	—
Total	£4,096		2·24d.	—

Submarine Cables Trust.

THE twenty-seventh ordinary annual meeting of the certificate holders of this trust was held on Wednesday at Winchester House, Old Broad Street, the Marquis of Tweeddale presiding.

The CHAIRMAN, in moving the adoption of the report of the trustees, said, that the revenue for the past year amounted to £22,997, being an increase of £105 over the previous year. Only £3,300 of the dividend to be received from the Eastern Extension Company for the quarter ending December 31st had been brought into the present revenue account, instead of the full quarter's dividend, as in former accounts. The total dividend and bonus for that quarter would amount to £4,315 7s., as in former years, so that, had they taken credit for the whole sum, the increased revenue would have been £1,120 instead of £105. At one time the December quarter's dividend was generally received before the closing of their books on April 15th in each year, but latterly it had not been received until the end of April or the beginning of May, in consequence of the half-yearly meeting of the Extension Company being held somewhat later than it used to be. It was hoped, however, that next year they might be able to pay the two coupons in full upon the due date without bringing in such a large portion of that interest, and the trustees looked forward to the time when the interest could be left out of the revenue account altogether until it was actually earned. The total expenses for the year had amounted to £1,159, which was an increase of £96 over the previous year. That was principally due to the extra cost of printing new notes for each of the existing 3,381 certificates. Notwithstanding that unavoidable expense, it would be observed that the total expenses were considerably less than was provided for by the trust deed. Coming to two principal features in the past year, the first was their return to the payment in full of each half-yearly coupon, and the second the completion of the sale of the Anglo-American Company's deferred stock, and the re-investment of the proceeds in dividend-paying securities. The reduction in the rate of the annual dividend which took place in 1885 prevented them from meeting certain coupons on their due dates. Between 1888 and 1891 they were one coupon behind, but since the latter date they had been able gradually to recover the lost ground, and for the last seven years they had paid an average of £6 8s. 7d. per cent., and therefore they had at last reverted again to the payment in full of the two last coupons on their respective due dates, which was a matter on which all connected with the trust were entitled to be congratulated. The proceeds of the sale of the Anglo-American deferred stock had amounted to £69,200, and the money had been invested in other securities of the character approved by the trust deed, and as the securities covered a wide area he thought they gave greater security to the trust. As showing the satisfactory position of the trust he might say that their investments showed an average appreciation of over 75 per cent.

Mr. J. DENISON PENDER seconded the motion, and the report was adopted.

The retiring auditors having been re-elected, the proceedings terminated with a vote of thanks to the chairman for presiding.

The Calcutta Electric Supply Corporation, Limited.

THE first report of directors, to be presented at the annual general meeting of the shareholders of the company at the City Terminus Hotel, Cannon Street, in the City of London, to-day, at 2 o'clock p.m., states that immediately upon the formation of the corporation, instructions were given to the managing agents in Calcutta to negotiate for the purchase of a site upon which to erect the generating station. After some little time a suitable site was acquired; but owing to the fact that the land was covered with native buildings, and to the necessity for the vendors in some cases taking ejectment proceedings to get rid of the occupiers, the corporation has only just recently obtained possession of the site. The question of the use of overhead wires in some of the streets of Calcutta has involved very protracted negotiations with the Government of Bengal, the Telegraph Department, and the Municipality of Calcutta. These negotiations have recently been concluded, so far as to permit of the contractors making arrangements for shipping the necessary cables. Now that the site for the generating station has been obtained, the contractors have entered into sub-contracts for the erection of the buildings and chimney; the whole of the cables and copper for the mains have been ordered, and a good portion of the generating plant is well advanced towards completion, so that shipment can be made immediately the buildings are ready to receive the plant. The question of the renewal of the company's concession at the expiration of the period for which it was originally granted, viz., 21 years, for a further like period, has been the subject of negotiation with the Government, and the directors have no reason to doubt that the assurance, given to the company before the issue of the prospectus, will be carried out. The auditors, Messrs. J. H. Duncan & Co., appointed by the board in the first instance, offer themselves for re-election.

The Oriental Telephone and Electric Company.

THE fourth ordinary general meeting of this company was held at Cannon Street Hotel on Wednesday, Mr. William Addison presiding.

The CHAIRMAN said that the net profits exceeded those of the previous year by £1,000. The expenditure had increased by the removal of the exchange to a more central position, and providing a new switchboard. They might expect similar expenses to arise. The rate of exchange had been more favourable to them than it had been for the past seven years. Business all round had been making steady progress, and the electric lighting had turned the corner. They were hopeful that the business already secured would show a fair profit. They would remember that the board had built up a reserve fund of £12,000, which was still intact, but owing to reconstruction could not be touched. They now suggested that a new reserve fund should be made to meet contingencies, repairs, and extending buildings and plans.

The report was then adopted.

Sir Auckland Colvin was re-elected a director in the place of Mr. Frost, a retired director, who did not seek re-election.

Stock Exchange Notices.—The Stock Exchange Committee have (1) appointed special settling days as under:—Thursday, May 5th.—Babcock & Wilcox, Limited—further issue of 8,000 ordinary shares of £10 each, fully paid, Nos. 14,001 to 22,000; South London Electric Supply Corporation, Limited—further issue of 9,159 shares of £5 each, £2 paid, Nos. 55,842 to 65,000. And (2) ordered the undermentioned securities to be quoted in the Official List:—Babcock & Wilcox, Limited—4,666 vendors' ordinary shares, Nos. 1 to 4,666, 3,333 vendors' 6 per cent. cumulative preference shares, Nos. 1 to 3,333, and a further issue of 8,000 ordinary shares, Nos. 14,001 to 22,000; Chelsea Electricity Supply Company, Limited—further issue of 8,000 ordinary shares, Nos. 32,501 to 40,500; House-to-House Electric Light Supply Company, Limited—further issue of 5,661 ordinary shares, Nos. 10,101 to 15,761; South London Electric Supply Corporation, Limited—further issue of 12,500 ordinary shares of £5 each, £2 paid, Nos. 43,342 to 55,841, and a further issue of 9,159 shares of £5 each, £2 paid, Nos. 55,842 to 65,000.

Eastern Extension Telegraph Company.—Subject to confirmation by the shareholders, the directors have declared a dividend for the quarter ended December 31st last of 2s. 6d. per share, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1897. The dividend and bonus will be paid on May 12th.

West India and Panama Telegraph Company, Limited.—The directors recommend a dividend for the six months ended December 31st of 6d. per share on the ordinary shares.

The City of London Electric Lighting Company, Limited.—Mr. George Herring has been elected a director of this company in place of the late Lord Suffolk.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending April 22nd, 1898, were £2,609 13s. 8d.; corresponding period (Easter week), 1897, £2,963 9s. 10d.; decrease, £353 16s. 2d.

The City and South London Railway Company.—The receipts for the week ending April 24th, 1898, were £998; week ending April 25th, 1897, £928; increase, £70; total receipts for half-year, 1898, £17,769; corresponding period, 1897, £17,612; increase, £157.

The Dover Corporation Electric Tramways.—The receipts for the week ending April 23rd, 1898, £125 18s.; total receipts to April 23rd, 1898, £1,821 2s. 2d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, April 22nd, 1898, were £576 13s.; corresponding week last year, £883 0s. 7d.; decrease, £306 7s. 7d.; passengers carried, 92,160; corresponding week last year, 117,731; aggregate to date, £6,892 1s. 5d.; aggregate to date last year, £7,117 5s. 8d.; decrease to date, £225 3s. 10d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending April 24th, 1898, amounted to £1,452; corresponding week last year, £1,770; decrease, £318. 1897, includes Easter Monday.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending April 22nd, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company Limited, were £2,964.

MARGINS FOR ECONOMY.

We referred some time ago to the very large margins for economy which existed everywhere in this country, and which, if taken in hand, would go a long way to the routing of foreign competition, which has become formidable from not having these wasteful margins. We might instance an example which came recently under our notice, and which serves to illustrate our meaning. In passing through a boiler shop we noted a locomotive type boiler in course of being stayed. Two men were at work upon it. They were tapping the holes for the stud stays, using the customary long tap which passes through both plates, and which in our young days was laboriously turned through by hand labour.

When flexible shafts were introduced they formed a very valuable and rapid auxiliary, and put the taps through the plates in very much less time than was possible by hand. On the boiler which came under our notice there were two men at work. One of these men was armed with a flexible shaft, but the other man was putting his tap through at about treble the speed effected by the flexible shaft. He was using a little compressed air three-cylinder engine contained in a small cylindrical box, and coupled up by a flexible India-rubber tube to an air compressor. At the rate he was doing the work he would save, as compared with his fellow workman, about, shall we say, only 10s. a week. It would be more. This would soon pay for a new apparatus to replace the old flexible shaft, which, in its turn, had replaced the hand work. But it occurred to us that if the shaft were changed for a small motor, the new tool would put to shame the rapid air tool we so much admired, and very soon the air tool also would be displaced by an electrical tapper.

We would not quarrel with the use of compressed air in the workshop. For some purposes it is better than electricity. For example, we think air is better than electricity for operating small direct lift cranes, such as are employed to lift work from the floor to a lathe. These small cranes are direct acting and easily controlled; they might as well be water-worked, except that water has the freezing objection to contend with, and there is more or less risk of leakage. They may not be very efficient, but they are cheaper than a small electric crane would be. But for portable drills, reamers, tappers, &c., electricity is certainly more easily applied, and more efficient than compressed air. For this class of work, involving the reaming or tapping of hundreds of holes, the element of speed is important and in electricity we find an agent which is peculiarly suited to small high-speed tools.

Great as is the economy to be derived from electric driving in large workshops, it is as nothing compared with the saving to be secured by its use in small shops. We mean such little shops as are run with a small vertical boiler and a little wasteful steam engine. In a recent investigation by the writer of the conditions of one of these small workshops, it transpired that the only regular work to be done every day was the driving of a fan using about a third of a horse-power during not more than half the day. To drive this fan required the engine and boiler, and if the boiler fire did not keep alight all night, it would happen that work could not start in the morning for an hour after starting time. This delay alone must often have cost from £2 to £4 per week. Then the boiler required either the constant attention of one man, or the partial attention of a striker, which meant delay. Fuel cost about £1. The total expense for power was thus quite £4 to £6 one week with another, or more than sufficient in a year to have applied an electric motor to each machine, and paid for current for a few years also.

But conservatism and ignorance stood in the way of the new motive power, and, so far, has prevented its adoption. Few realise how very partial is the running of machine tools. Often they do not work, even when busy, half the time. There is stoppage for tool grinding, resetting, calipering work, changing work, &c. Yet all this waste time the shafting is going round, and fuel is consumed. Few people are aware of the extent of small industries in large towns, and especially in London, nor of the enormous waste of power involved in turning round the shafting.

One such shop lately seen by us was driven by a gas engine placed quite 100 feet from the work. To do work of only a quarter horse-power pretty well loaded up a 6-horse gas engine. In fact, loaded or unloaded, the engine seemed to record about the same number of explosions. The gas engine might have driven a dynamo, and all the shafting might have been abolished. It is all very well to say that if shafting is kept in order it will absorb much less power than is usually the case. But in practice it is the small shop which is worst off for shafting, because there is not the staff to look after it, and in every respect the small shop is at a very great disadvantage, both in respect of the fuel consumption for the energy output of the engine and in respect of the mechanical efficiency of the organs of transmission. The dead load bears so large a ratio to the live load, and moreover, the dead load is run 10 hours a day, where the live load is run from two to six hours only. Gas engines pay in small shops as compared with steam, but gas engines do not enable us to dispense with shafts and belts, and they also must run all day. It is very much in the time not worked that such large economies are possible with electricity.

Even where steam is employed the attempts to economise it are very half-hearted. We have seen live steam used for heating where exhaust steam would have done as well. We have seen a drying stove heated by the steam pipes to the engine, which were left bare on purpose to help the stove. The owners would not listen to any explanation that the resulting wet steam was very prejudicial to the economy of the engine, and there was no water separator. This sort of economy—for the owners believed that in thus using the engine steam pipes they were saving a set of pipes, and also so much non-conducting covering is really very common. Moreover, these same pipes had nine bends where two only were necessary. Had this pipe been made direct and covered the lengths of pipe saved would have been sufficient to have made up the stove heat, for the steam pipes were not wholly on the stove. Some of them were out in the open air and bare in places to the rain.

And people talk of hard times. All the examples cited have come under the writer's direct attention; they are but samples of thousands more or less parallel instances of waste, and we are bound to say that in many similar cases pressure to remedy has come from below—from the man at a few shillings a week, and has been blocked by the man above, whose refusal was usually that he did not see why such or such an action would save fuel. Electrical driving, even when it comes from outside generated power, appeals to such men when they happen to get it because they are keen to reduce a metered charge. These same men will go on paying for coal in excess because they have not the knowledge to teach them how to estimate where the losses come in. We have known them pay for expert advice, and refuse to follow it because they could not understand "*why it was so.*"

COMMERCIAL FORMS OF ELECTRICAL RESISTANCES FOR LIGHTING AND POWER PURPOSES.*

By Ll. B. ATKINSON.

The functions of a resistance being primarily to regulate or determine the amount of the current, which it does by its resistance, its second function is to dissipate the heat produced by the electric power expended on the resistance. This becomes a matter of cooling surface, and leads to a wide range of possible designs.

Speaking generally, then, in considering electrical resistances, the points to be considered are the (1) material of which the electrical resisting circuit is composed, (2) the nature of the support for such circuits, and (3) the material for insulating the circuit from the support, and, in addition, the nature of the switching mechanism for varying the amount of resistance in circuit.

(1) Material of which the Electrical Resistance Circuit is Composed.

Since all conductors offer resistance to the passage of the electric current, any conductor may be used as a resistance. The following table shows the resistance of 1 centimetre in length of various metals and alloys, carbon, and liquids, the cross-sectional area of the specimen being 1 square centimetre and the temperature 0° C.

Table of Specific Resistances.

Table I.

	Resistance per cubic centimetre.	Percentage variation per degree Centigrade.
Silver	1·504 microhms	·377
Copper	1·598 "	·388
Iron	9·716 "	·453
"German silver" ...	20 93 "	·03
Platinoid	51·0 "	...
"Manganin" ...	52·0 "	practically *nil*
"Eureka"	60 0 "	"
"Rheostene" ...	100·0 "	"
Carbon	4,200-40,000 "	—·2
"Relugite"	3·2 to 3,200 ohms	—·2
Solution of soda (10 per cent. solution)	11·5 ohms	...
Solution of zinc sulphate (density 1·405)	28 3 "	...
H_2SO_4 (density 1·10)	1·37 "	—1·7

This table is only to be used as a guide, since, except with pure silver and copper, as all the other materials are of somewhat undefined composition, and the resistance of alloys and carbon varies greatly with their chemical and physical condition. It will be observed that several of the materials used are special alloys, for the most part of nickel and manganese, which, in addition to having a very high resistance, have a very small temperature coefficient, which is important, as resistances are often worked to a temperature of 200° C., causing a very considerable variation of resistance.

* Abstract of paper read before Northern Society of Electrical Engineers.

An interesting example of this is in the use of iron wire when it is approaching a red heat, in which case it will be found that the resistance rises so rapidly, that a very large increase of E.M.F. will only cause a very small increase in the current, because as the E.M.F. is raised, causing a small increase of current, this raises the temperature, so that the resistance rises almost as fast as the E.M.F.

The writer some years ago used this property for arc lamp resistances, when even if the lamp was cut out, the permanent rise in current was quite small.

The metals, solids, and liquids shown in the table are those which are most frequently used for making resistances, and with regard to these, the usual form of the metals and alloys is in the shape of wire or strip, the former generally wound into coils.

Carbon may be used either in rods, in which case the ends should be electro-coppered, and the connections clamped and soldered to the copper, or the carbon may be used in the form of flat plates piled on one another.

The material, "Relugite," shown in the list, is a new material, now being put on the market by the Electric Insulation Syndicate, of Cardiff, and having an incombustible base, such as asbestos, in which is deposited conducting carbon, and the specific resistance of which can be made as required within the limits given, and this material also may be used either in strips, the current passing from end to end, or in plates or layers, through which the current passes.

Liquids are used generally where high resistances are required, and are on the whole an unsatisfactory form of resistance, as the solutions creep and cause loss of insulation on the circuits to which they are attached, whilst the liquids also leak or evaporate, so that they have to be made good, and the composition and resistance is constantly varying.

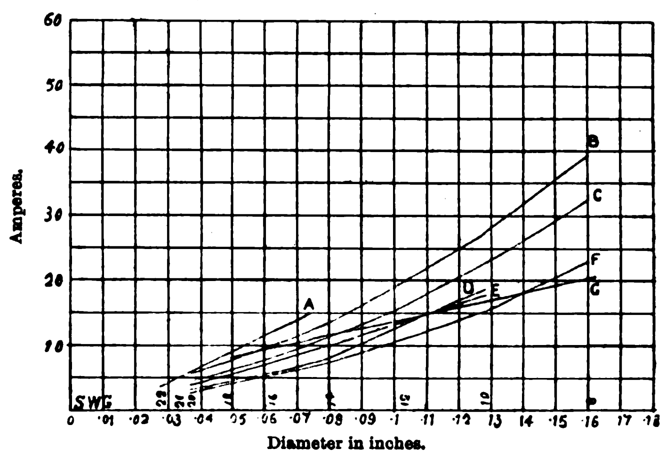
Carrying Capacity of Resistance Materials.

It is important to determine what is the carrying capacity of the wires, strips or plates, of which a resistance is composed; this being defined in relation to some particular allowable rise of temperature.

The rise of temperature to be allowed is probably the point on which the greatest difference of opinion seems to exist among manufacturers.

It is somewhat curious that the fire insurance offices who define to a nicety the insulation of the circuit and other quantities, are exceedingly vague on what is probably one of the chief fire risks that are run, most of the offices satisfying themselves by merely stating that the resistance should be constructed of, and mounted upon incombustible material, and that no combustible material should be within a foot of the resistance.

Diagram of carrying capacity of metal wires.



A, Iron wire coils on ½-inch bar, 280° C.; B, Rheostene 150° C.; C, Rheostene 100° C.; D, Iron 50° C.; E, Silver 50° C.; F, Rheostene 50° C.; G, Tinned iron maximum safe current.

Since most organic matters and fabrics char at a temperature of 200° C., the writer thinks that that limit at all events should never be passed, and probably the rule defining that the maximum temperature of the hottest part at the maximum working load should not exceed 150° C. would be a safe rule.

The principal methods of dissipating heat from resistance are by radiation, air currents, and in certain cases by circulating liquids, such as oil or water.

The amount of heat radiated at the temperatures discussed is not large, and the use of liquids for cooling is not common, so that practically speaking cooling by air or currents is the usual method.

It is obvious, therefore, that the designs should be such as to allow a free circulation of air through those parts where the heat is being produced.

Wire Resistances.

For this reason where wires are used, it is advantageous that the diameter of the wire should be small, so as to give a maximum surface for a given cross-sectional area, and to carry the requisite current a sufficient number of wires should be placed in parallel.

Again, where wires are wound into coils, these coils should be open, and there should be a space between successive turns of the coils of 2 or 3 diameters to allow an effectual passage of air.

In the case of long coils placed vertically, the upper parts of the coil become far the hottest, as the air heated by the lower coils is the only cooling medium.

It is almost impossible to give any general rule as to the carrying capacity of wires in coils.

The Diagram shows the relation between the diameter of the wire and the carrying capacity of wires stretched out straight in the air, and for certain temperatures.

If the wires are in coils drawn out so that the space between the wires is about 2 diameters, the current the wires will carry for the same temperature will be about one-third of that given by the diagram.

One of the most effective forms in which wire can be used is in the form of wire gauze, and the best class of gauze is that in which the longitudinal wires carry the current, the wires all being in parallel connection, whilst the cross threads carry away the heat, and in this case the load to be carried by a given wire is double that given in the table.

A great difficulty occurring with wire resistances, particularly where alloys, such as German silver, are used, is that the wires become brittle or rotten, and break, causing short circuits, and danger of fire.

In the case of resistances enclosed in boxes so that only the outside surface will dissipate the heat, the carrying capacity of the wires is much less than that given in the table, and the ultimate carrying capacity of the resistance will depend on the surface of the casing exposed to the air, and for a temperature of 150° C., the total external surface should be about 10″ per watt to be dissipated.

The surface for this purpose may be increased, if of metal, by casting ribs or fins upon the casing, so as to increase the surface.

Some resistances are only required for a short time at intervals, such, for instance, as resistances for starting motors, and here the element most to be considered is not the surface on which depends the power of steadily dissipating heat, but the total specific heat of the parts on which depends the rise of temperature with the given load in the time for which it is to be used, and in this case materials having a high specific resistance with large bulk may be used to advantage, or if fine wires are used, they may be imbedded in materials such as enamel or sand or asbestos, which will absorb, by conduction, the heat from the wire itself.

Carbon Resistances.

A common form of carbon resistance consists in the use of ordinary lighting pencils, with the ends coppered and connected up by clamps.

These resistances for testing purposes can be run at a very high temperature, but they dissipate heat badly, they are very liable to be broken, and are not often used for resistances which may have to be transported.

Carbon resistances made up of plates placed in a frame are often used, and they have the advantage that the resistance may be varied by screwing them up more or less tight by a clamping screw.

In this case a very large part of the resistance is due to the resistance of the surface of the contact between the layers, and due, also, to the fact that the current travels in the plane of each layer from the points of contact at the surface, of one set of plates to those of the next set; these, in most instances, not coming opposite to one another on the plates.

In other words, except when the plates are screwed up quite tight, the current is travelling by a zig-zag course through the pile of plates, and it is principally this which enables the resistance to be varied.

The material previously mentioned, viz., "Relugite," is used in the same way, and with the same results, but it has a great advantage over the carbon resistances, in that the material being flexible and elastic, a much wider range of the screw is obtained, so that the resistance can be varied more gradually, whilst the tendency with solid carbon resistances for the plates to actually break contact and so set up an arc is got over.

The chief difficulty with carbon resistances is that they present a very small cooling surface.

This difficulty has been obviated in the case of "Relugite" resistances by interposing metal plates between the plates of material, which metal plates are larger than the plates of the material, and thus serve to conduct the heat from between the plates, and to present a large surface for the air to pass through to cool them.

Liquid Resistances.

The commonest form of liquid resistance is a wooden tub filled with water in which is sulphuric acid, common salt, washing soda, or other metallic salt, to render it more or less conductive, and in which are immersed plates leading in the current.

Such resistances cannot, of course, rise above the temperature of boiling water, and they absorb a large amount of heat due to the large latent heat of steam.

Such an arrangement is, of course, a very rough one, and only used for temporary purposes.

For permanent installations iron or earthenware jars or pots are used, containing solutions, and having electros of various forms which can be moved in relation to one another.

(2) Materials for Supporting Resisting Wires or Materials.

In the early days of the use of electric power, resistance wires or coils were usually strung in wooden frames, and the writer believes he was the first to introduce into the market standard patterns of resistances, in which the supports were wholly composed of incombustible material, that is to say—iron frames carrying slate or porcelain insulating parts, to which were attached the resisting wires.

These resistances may be, and usually are, provided with a switch having a number of contacts, which enables, more or less, the resisting wire to be included in the circuit.

A class of support previously mentioned is the use of enamel on a base of iron. In this case the iron is first enamelled, to give it an insulating coating; the wires, which are very fine, are then placed on the enamel, and covered with thick coating of enamel, which is then fused, so that the wires are firmly imbedded in it.

The resistances known as the Carpenter resistances, and the resistances in most heating and cooking apparatus, are arranged in this manner. In this case the enamel carries the heat from the wire to the iron supports, which then distributes it, and forms the cooling surface.

In the case of the "Relugite" resistance material, this is carried in iron frames, generally on pillars or bolts passing through it, the insulation being enamel, and in certain cases mica or asbestos sheets are used where flat surfaces are to be insulated.

In a form of liquid resistance which the writer has used, the current enters at the bottom of one tube and leaves at the bottom of the next tube, a wire fork or bridge being raised or lowered in the tubes.

A curious phenomenon occurs with such an arrangement, the complete explanation of which the writer is unable to give, viz.: That using lead plates at the bottom of the tubes and a copper or iron bridging piece, the resistance and heating effect is not equally divided between the tubes, but is largely concentrated in one of them.

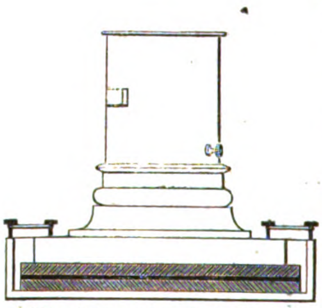
(To be continued.)

TRIAL OF THE SULLIVAN UNIVERSAL GALVANOMETER ON A TORPEDO BOAT.

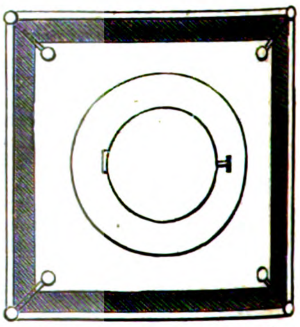
The Sullivan Universal Galvanometer has recently been tried in the English Channel on an Admiralty torpedo boat steaming at various rates of speed. The object of the trials was to determine the effect on the working of the instrument of the excessive vibration experienced on those vessels. Throughout the observations the galvanometer was mounted in a cabin aft almost immediately over the propeller, with the instrument facing towards the bow, and in the first instance was screwed to the cabin table in the usual way without a cushion of India-rubber or other vibration absorbing material interposed between instrument and table. Thus the vibration of the boat was communicated direct from table to galvanometer. The distance between mirror and scale was 42 inches. The following is a record of the behaviour of the galvanometer under these conditions:—

The boat was found to be most vibratory at 300 to 350 revolutions of the engines per minute (about two-thirds full speed). The observations noted below were all made at that speed.

So severe was the vibration then experienced that a glass of water placed in a receptacle on the table was in a few minutes more than half emptied. Nevertheless, the instrument behaved very well.



Side of tray removed showing the hair felt pad.



Showing galvanometer in tray and rubber stays at four corners.

Only an occasional movement of 30 to 50 scale divisions was noticeable. In every case this disturbance was of the nature of a sharp throw, the spot of light immediately returning to zero without oscillating or passing that point. At all other times there was no perceptible unsteadiness.

The galvanometer was then mounted as follows, and a further series of observations made:—A thin wooden tray was screwed down to the table, and inside were laid two thicknesses of hair felt, each of them ·8 inch thick, together making a pad or bed about 1·5 inch thick when not compressed and 1 inch thick when the galvanometer was on it. The internal dimensions of the tray were 12 inches by 12 inches by 3 inches deep, thickness of sides ½ inch, and bottom ½ inch. The flat portion of the wooden base of the galvanometer stood just below the top edge of the tray. At each corner of the galvanometer base (and in its screw holes) and at each corner of the tray was a screw, an India-rubber band connecting each pair of screws, so that at each corner there was an elastic stay sufficiently strong to keep the galvanometer in position when the boat rolled and pitched heavily, and yet the India-rubber bands did not transmit vibration from the tray to the instrument.

With this arrangement and the propeller doing its worst the galvanometer disturbance was reduced to an occasional throw of five divisions only, increasing at odd intervals to about 20 divisions.

Apparently this occasional and slight increase of unsteadiness coincided with sudden changes of the helm which combined with the ceaseless vibration from the propeller produced a severe jarring effect. At other times the spot again was absolutely steady, and in all cases the coil immediately resumed the zero position without oscillation.

Hitherto the galvanometer had been on open circuit. It was now short-circuited. The result was to still further reduce the maximum and occasional throws which had been noticeable upon changes of the helm from 20 to 10 divisions.

Some measurements then were made over the full range of the scale with perfect ease, the coil when deflected being as steady as when in the zero or resting position either on open or closed circuit.

During one part of the trials a short and choppy sea was encountered causing the boat to be very "lively" with sudden irregular movements, but, notwithstanding this effect and the excessive vibration of the propeller, the galvanometer, as before, preserved its equilibrium. It should be mentioned that the delicately suspended coil was in perfect balance.

An ordinary and less sensitive iron-clad marine galvanometer set up alongside the Sullivan, and in the same way, vibrated to such an extent that the spot of light continually left the scale on either side and was often invisible, observations of any kind with it being cut of the question.

In view of the great galvanometer disturbance which mechanical vibration, apart from rolling and pitching, so frequently sets up on board ship, preventing any reliable observations being made, these trials may be considered interesting as showing the steadiness of the new galvanometer under the severest test to which any such instrument could possibly be subjected, and Mr. Sullivan is to be heartily congratulated on having achieved such perfect control over one of the most delicate of electrical measuring apparatus.

The Sullivan Universal Galvanometer, mounted on a cradle board to imitate the rolling and pitching of a vessel, may be seen in operation at the offices of Mr. H. W. Sullivan, 19, Great Winchester Street, E.C., the inventor and sole maker.

SUBMARINE CABLES IN TIME OF WAR.*

TRADE AND TELEGRAPHS.

America, it is stated, has claimed the right to cut cables connecting Cuba with the islands of Jamaica and Bermuda, and Spain has objected on the ground that the Telegraphic Convention protects these lines. Already the electric communications between Key West and Havana have been seized by the Americans. The whole question of transmission of cablegrams through neutral territory and along wires owned by neutral shareholders bristles with delicate questions and interesting points. In the course of inquiry into the subject, which not only concerns the belligerent Powers, but intimately affects our own trading and commercial relations with the Western hemisphere, a representative interviewed a gentleman whose position and experience entitle him to express an authoritative opinion upon the manner in which hostilities may interfere with the working of the submarine channels of communication between the Old World and the New.

"The Americans," he said, "I have no doubt, were within their rights in taking control of the cables between Key West and Havana. They belong to an American company, and the Government of any country granting a license to land cables invariably reserves to itself the right to enter into possession and to work them, accounting to the shareholders for the receipts meanwhile. The proprietary company of the Key West cables is the International Ocean Telegraphic, which is leased to the Western Union, the great company of America. But when you speak of the Americans cutting the cables which connect Cuba with the British island of Jamaica a different question is raised, as the line from Batabano to Cienfuegos, and the double line thence to Santiago de Cuba, on the southern coast of the island, are both British property, for they are owned by the Cuba Submarine Company, which has its offices in London. It is an English concern. From Santiago de Cuba to Holland Bay, in Jamaica, another British company—the West India and Panama—owns the cables."

"Is there any provision in the Convention to protect this property?"

"Cables are not neutral in time of war. The Submarine Telegraph Act of 1885 scheduled an international Convention, which authorised and made it legal. This Convention between the civilised States of the world was for the protection of submarine cables against wilful damage, &c., but there was this express provision in it: 'It is understood that the stipulations of the present Convention do not in any way restrict the action of belligerents.' I imagine, therefore, that there is nothing to prevent any belligerent cutting cables, but if he wilfully does so, in the case of a cable belonging to a neutral country, that country, or the company owning the line, would have a claim against the offending Power for the destruction of property. But still, the countries of the world could not complain diplomatically of such damage, as they would be justified in doing supposing that a belligerent fired upon the Geneva Cross. Let us take it that we were at war with Russia. Russia would be at liberty to cut any of our cables without raising an international outcry, but if Russia, at war with us, were to cut the cables of an American company, my impression is that the aggrieved party would have a claim against the Russian Government for damages. But it is a legal question."

"If the United States and Spain both recognise the principle, as they now do, that the neutral flag covers enemy's goods, except contraband of war, and that neutral merchandise, except contraband of war, is not seizable under the enemy's flag, why should not the same protection be afforded to cables?"

"Well, it may be argued that a cable is an effective engine of destruction, ordering troops and fleets to move, and so forth, as any other appliance used in war, which Spain has declared contraband."

"How do the two belligerents stand in regard to cables?"

"Should the United States cut cables in the West Indies, Spain may retort by grappling up cables, say, three miles off the Irish coasts—*i.e.*, outside our territorial limit. The Western Union Company have two cables across the Atlantic, and the Commercial have three, from Waterville in Ireland, to Canso in Nova Scotia. I should say that Spain could break these lines without breach of international agreement. It would be equivalent to a gun fired upon American property."

"But supposing Spain should not only grapple the American-owned cables—those of the Western Union and Commercial—but also cut the lines belonging to the English or French companies, what would happen?"

"I should think that such wilful damage to neutral property would be resented by the proprietary companies, backed up by the British Government."

"How can Spain communicate with Havana and Puerto Rico?"

"She can do so by using lines that run through British territory throughout; for, as far as I know, there is no intimation of telegraphic interruption with Puerto Rico. The route for a Spanish message would, therefore, be by one of the English companies to Halifax, Nova Scotia, and thence to Bermuda. The British have now a cable from the Bermudas to Jamaica, calling at Turk's Island, and between Jamaica and Puerto Rico there are, as I have said, two cables. So that Spain could have communication with both of her colonial possessions in the West Indies without touching American territory."

"But she would be entirely dependent upon the good offices of England. Has she no alternative route?"

"She can cable direct from Cadiz to Teneriffe; but from Teneriffe to St. Louis (Senegal) the cable is French, and from St. Louis to Pernambuco, crossing the Equator diagonally, the cable is British. England is placed in rather a singular position. To reach the Windward Islands we must enter Spanish territory at Puerto Rico. I can conceive it would be a wise measure to divert one of the cables from Jamaica, at present landing at Ponce, in Puerto Rico, to the Danish island of Santa Cruz direct, and thence to Trinidad and Demerara; and that plan, I should say, would be adopted. It would still leave Puerto Rico with one cable, landing at San Juan, from Jamaica. The French can, on the other hand, reach their coaling station at Martinique without touching Spanish territory. They have lines which go from Brest to Cape Cod, near to Boston, and they have recently laid a cable from New York to Hayti, which lies midway between Puerto Rico and Cuba, and thence to Martinique and to Cayenne. The French have also a cable from Santiago de Cuba to Hayti."

"Is it not possible to reach Jamaica and Cuba by way of South America?"

"Yes, by a roundabout route, traversing the Continent. Our Admiralty would probably direct the movement of ships in the Pacific by sending messages through lines owned by Englishmen and worked by Englishmen, first to Lisbon, and thence to Pernambuco, in Brazil, the cable being the property of the Brazilian Submarine—a British company—thence to Monte Video (Western and Brazilian Company, also British), then to Buenos Ayres (nominally Argentine, but actually British), thence to Mendoza, and so on to Valparaiso (Chili), and along the West Coast of South America to Chorillas, in Peru, hugging the land, whilst a competitive American Company takes a seaward curve to the same place. From Chorillas there are two lines—one to St. Helena, and the other to Payta, and one of them going on to Buenaventura, and then to Panama, across the isthmus of which, at Colon, a cable, which is British, connects with Jamaica, and thus completes the circuit. But you will notice that the Spaniards would be reluctant to use this route, as the links from Chorillas to St. Helena and Payta are owned by Americans. Similarly, though the map shows a possible communication *viâ* the North-East Coast of South America from Pernambuco to Cayenne, the section between Para and Cayenne is invariably broken, so no telegraphic communication with the West Indies by that route is possible."

* *Daily Telegraph.*

SUGGESTIONS FOR IMPROVEMENTS IN POWER PLANTS.

The recent attention drawn to the wastefulness of the auxiliary engines of certain ships of the American Navy, and also of our own ships, notably the *Diadem*, has its counterpart in similar attention to the wasteful items of stationary plant. The subject is discussed by Mr. Bennett in *Cassier's Magazine*, the author's conclusions pointing to the use of electric motors in place of small engines and direct acting pumps. The main engines are always fairly efficient and, less the small loss of transmission, this same efficiency ought to be obtained in auxiliary plant also, whereas auxiliary plant is almost invariably very wasteful. As a railway or a light plant must always have one unit at work, or there will be a storage battery to draw upon, there need be no fear of the auxiliaries being too dependent or liable to interruption. Where the main engines are of condensing type the steam of auxiliary engines has been very much used for feed-water heating, and it is this apparent utilisation of the exhaust which has strengthened the hold of the simple small steam driven apparatus by a false assumption of economy. As a matter of fact, if flue feed heaters were applied to use the waste gas temperature there would be no field for using the exhaust of wasteful small steam auxiliaries, and their place would be seen to be better filled by electrical motors. We need not follow our author into his recommendations of the flue feed heater or economiser, for though comparatively new to America it is old in England, at least in the north where fuel is cheap, though much less common in the south, where its economy would be so very much more marked.

The economiser is as necessary a step in steam production as is the second cylinder of the compound engine in steam using. It represents the principle of stage heating or counter currents, and in large plants may well be divided into two or more divisions in series so as to leave to the boiler proper little else to do than to give the latent heat necessary to turn hot water into steam. By this means alone can the waste gases be reduced to a temperature sufficiently low to fully justify a mechanical draught. If the waste gases are sent away very hot they may just as well assist to produce draught by a chimney, and it is not of much use adopting a power driven fan unless at the same time the waste gases are correspondingly reduced which can only be done by stage heating of the water, which is finally boiled off.

Moreover, where electricity is available there is no great need of a wasteful steam engine to drive the draught fan. Economisers are somewhat of a check upon a good draught, and are desirably associated with a fan which will revolve for less heat expenditure than a chimney will perform the duty, but as said above, if the chimney is to be abolished there must be a properly low temperature of the escaping gases.

THE SOCIÉTÉ INTERNATIONALE DES ELECTRICIENS.

Sitting of April 6th, 1898.

The annual general meeting took place on April 6th, with Dr. D'Arsonval in the chair. The general secretary was absent through illness, his place being filled by M. J. Laffargue, secretary. After the report had been read, the names of some candidates for admission were presented, and also some books. The voting list was then closed and tellers were appointed.

M. Armengaud read the report of the Committee of Accounts, which was received with approval.

M J. Laffargue then read a paper on "The Distribution of Electrical Energy in Germany."

He mentioned that last January he had the pleasure of accompanying on some professional business in Germany, M. Charles Bos, municipal councillor of Paris, and reporter on various electrical questions. He had occasion to visit a large number of distributions of electrical energy, and he wished to bring before the notice of the society some of his observations, confining himself, however, to technical matters.

Installations in Germany are on a large scale and very numerous, both for distribution properly so-called and for traction.

Sometimes these installations are combined, and a single central station effects both distributions. We have already given the statistics of the central stations of Germany. To these must be added since September 1st, 1897, 56 towns provided with 957 kilometres of electrical tramways, absorbing a power of 21,465 kilowatts; part of this power is furnished by the central stations used for both distribution and traction, of which we have spoken above.

The distribution stations are large, spacious, well managed, and very clean. In most cases they are situated near railway stations or near rivers, and sidings are always arranged to bring the coal up to the station. The boiler rooms are high and well ventilated; the boilers have a clear space between them and are easily accessible. The engine rooms are large and are capable of being enlarged still further. One can walk about freely amongst the engines, and approach all the parts. The distribution boards can be seen well from all parts of the room and the regulation is easy. For street canalisation only armoured lead-covered cables are used in Germany, made either by Siemens & Halske, or by Felten & Guilleaume. Under the pavements they are generally laid directly in the earth; under the roads they are sometimes protected in iron tubes, or in iron cases made specially. The wires intended for traction are nearly always overhead, at least as far as distribution wires are concerned. At various places, in order to prevent the falling of the telephone wires, iron wires are stretched across which add still more to the unsightly appearance of the overhead wires at cross-roads.

The indoor installations of the consumers are very bad in Germany. Notwithstanding the very strict regulations that we read of in various journals, we meet with few good installations. We see wires laid right against the walls, and merely held in place by hooks. Installations on porcelain insulators are numerous. The fitting up is often defective, metal covers scarcely fixed at all being used. Installations used both for gas and electricity are very numerous, and the wires are laid over the gas appliances without any precautions being taken. Several engineers told us that this state of affairs was now going to be looked into and altered.

We then examined some of the installations in the principal distribution stations.

At Frankfort we found a municipal central station under State management for the last two years. It was installed and is still worked by the Brown and Boveri Company of Baden. The engine room contains four compound tandem horizontal steam engines of 750 H.P. at 70 revolutions a minute, each driving directly four alternators of 500 kilowatts at 3,000 volts; a fifth engine of 1,500 H.P. is in course of erection.

The distribution board is in the centre of the room placed at a certain height; in the basement are the appliances for condensation.

The mains are formed of Felten & Guilleaume concentric cables; the transformers are placed at certain centres of distribution. At the end of the season of 1897, the installation included 40,825 incandescence lamps, 624 arc lamps, and 133 motors of 1,063 H.P. The public lighting included 100 arc lamps of 10 amperes and 800 incandescence lamps. Amongst the various installations of motive power, we particularly admired that of the *Frankfort Gazette* where three motors of 30 H.P. drive printing presses, and where there are a series of smaller ones for passenger and luggage lifts.

The cost of supplying the electrical energy is ·15 franc the kilowatt-hour for lighting and ·15 franc for motive power. At Frankfort, experiments are now being made in traction by accumulators, and are being carried on by the Pollak Accumulator Company.

This company has extensive works where the manufacture is being developed considerably. Besides Messrs. Pollak's special commutators, which serve for the formation and the charging of the accumulators made at the works, there are rotary transformers and motors driving dynamos. Cables connected to a post placed not far from the works enable the charging to be effected with a constant difference of potential of the accumulators placed in cars under the seats. The car passes under movable contacts and the charging at once commences automatically. In four minutes the charging is concluded.

We also visited while at Frankfort the works of the old firm of Lahmeyer, and of Hartmann & Braun; we found everywhere extensive works with electric transmissions and driving gear, and also fresh buildings in course of construction for extending the installations.

At Cologne there has been a municipal electrical station since 1891, established under the best possible conditions, luxuriously even. The distribution is effected by alternating currents at 2,000 volts, with transformation at the consumers' houses to 72 or 110 volts. The engine room, which is elegantly fitted up, contains four Sulzer compound engines of 650 H.P. at 85 revolutions per minute, working directly four Helios alternators of 450 kilowatts, and exciters of 110 volts and 300 amperes. The alternators are coupled in parallel with auxiliary resistances. The distribution board is placed in the middle of the room against the wall at a certain height. The arrival and departure wires are placed for each machine on a special board. On the fore-part is a switchboard, which, by the aid of levers, enables the chains to be manipulated that work the interrupters, and the circuit-breakers of the high tension circuit and of the exciting circuit. The circuit-breaking interrupters, the starting point of the high tension feeders, and also the charging resistances, are, in fact, placed in a special closed room, situated below and behind the distribution board.

The mains are in the form of concentric armoured lead-covered cables, placed in wooden cases. The central station has undertaken the lighting of the streets in certain quarters, and the feeding of some motors; sub-stations for transformation into continuous currents for traction are going to be supplied.

At Hamburg, the new station in the Carolinens-Strasse supplies three sub-stations of accumulators placed within the town, and furnishes the tramways with the necessary electrical energy. This station has a large boiler room containing 16 boilers, each with 250 square metres of surface, and an engine room of 17 metres by 50, in which are installed six triple expansion vertical steam engines of 1,200 H.P. at 100 revolutions per minute. Two of these engines each work two Schuckert dynamos of 500 kilowatts at 300 volts, three each work three similar dynamos at 600 volts, and the sixth engine drives a dynamo of 1,000 kilowatts at 600 volts. The distribution board is very well arranged; on the wooden part are placed all the arrival wires of the engines, and on the sides are the departure wires of the circuits.

There is also at Berlin the Post-strasse station, situated within the town, and containing five compound vertical steam engines of 500 H.P. at 120 revolutions a minute. These engines work five Schuckert dynamos of 400 kilowatts at 250 volts, which effect a special distribution.

The first electric station was established at Berlin in 1885. The distribution is effected by three wires at 220 volts. There are now four large stations and one sub-station, all connected with one another and feeding the same system of distribution. The station of the Markgrafenstrasse contains six compound vertical steam engines of 300 H.P. at 82 revolutions per minute, working dynamos with internal poles and also three rotary transformers of 400 kilowatts. The primary of these transformers is fed by the triphased currents coming from the station of Schiffbauerdamm. The secondary circuit is formed by a dynamo of 250 volts. The station of Mauerstrasse contains two steam engines of 300 H.P. at 82 revolutions per minute, four engines of 1,000 H.P., and two engines of 1,500 H.P. Amongst the dynamos are two of 238 kilowatts, four of 364 kilowatts, and four new dynamos of 650 kilowatts. In the station of the Spandauerstrasse are three steam engines of 1,000 H.P. and four of 1,500 H.P., and also six dynamos of 364 kilowatts and eight of 650 kilowatts. The station of Schiffbauerdamm contains three engines of 1,000 H.P., two of 1,500 H.P. working respectively six dynamos of 364 kilowatts and two triphased alternators.

The sub-station of Königin Augusta Strasse is fitted with two batteries of 138 accumulators of a capacity of 12,000 ampere-hours.

There is now in course of installation at Oberspree a large station of 50,000 H.P. which is to effect the distribution of electrical energy in the suburbs of Berlin. Up to the present the electrical tramways in Berlin have been worked partly by overhead wires and partly by underground cables, the energy being supplied by the station of Mauerstrasse, from Behrenstrasse to Treptow, and from Treptow to Dönhoffsplatz. Experiments in traction have also been made with accumulators on the line from Berlin to Charlottenburg. At Berlin we also visited the works of the Allgemeine Elektricitäts Gesellschaft, and at Charlottenburg, the workshops of the firm of Siemens and Halske. The central station of Leipsig is situated outside the town; it comprises a system of distribution by continuous currents which supplies consumers living near, and a transmission by triphased currents to a sub-station situated within the town. A rotary transformer works a continuous current dynamo of 350 kilowatts at 250 volts, and also three *survolteurs* for Tudor accumulators. The whole of this installation was provided by the Siemens & Halske Company. At Leipsig there are two different traction companies working different systems, one running 80 cars and the other 185.

The town of Munich has up to the present only undertaken public lighting and experiments in traction. The distribution is effected at 660 volts and feeds about 850 arc lamps. The station of Muffatwerk contains at present a turbine of 200 H.P., working by transmission two Schuckert machines of 66 kilowatts at 330 volts, and three similar machines of 26 kilowatts; this same transmission is also driven by a steam engine of 300 H.P. Two other engines of 350 H.P. have also just been installed, and one of 700 H.P., and one of 1,000 H.P. is now in course of installation. M. F. Uppenborn, engineer-in-chief to the municipality, explained to us the projects that will shortly be put into execution, and which include three central stations using triphased currents with sub-stations using continuous currents, the whole comprising a power of 21,000 H.P.

At Nuremberg, there is a municipal central station which possesses four alternators of 450 H.P. at 2,200 volts, and one of 1,000 H.P. In the town a special system of traction by trolley is used. But what is most worthy of notice is the large establishment of the Elektricitäts Aktien-Gesellschaft, where at every step we meet with electric transmissions, machinery, experimenting rooms, foundries, and erecting rooms. The company is erecting by the side of the *first* establishment a second, which will perhaps be still further developed.

At Strasburg, the central station supplies electrical energy for distribution, properly so-called, and for traction. The steam engines, five in number, are compound vertical engines supplied by the Société Alsacienne, two of 200 H.P. driving at the same time a triphased current alternator of 80 kilowatts, a continuous current dynamo of 125 kilowatts at 500 volts, and three engines of 300 H.P., each driving a triphased current alternator of 280 kilowatts. It will be interesting to give a few particulars as to the cost price and the selling price. Generally speaking, the cost of coal is from 12 to 18 francs the ton, and we reckon about 3 kilogrammes per kilowatt-hour produced.

At Frankfort the cost price of the kilowatt-hour is ·305 fr., including interest and sinking fund. At Cologne and at Düsseldorf the cost prices are respectively ·192 and ·126 fr., including interest and sinking fund. The selling prices vary from ·08 to ·1 fr. the hectowatt-hour for lighting, and from ·025 to ·035 fr. for motive power, with reductions amounting to 40 and 50 per cent. We will conclude by saying that in March, 1897, Germany possessed 1,025,785 incandescence lamps of 50 watts, 25,024 arc lamps of 10 amperes, and a power of 21,800 H.P. for engines installed. At Berlin, at the end of the season 1896-97, there were 196,076 incandescence lamps, 9,173 arc lamps, 357 apparatus of various kinds, and 2,056 motors of 7,475 H.P. It must be remembered that in 1888-89 there were 17 motors of 60 H.P., in 1892-93 about 232 motors of 785 H.P., and in 1895-96 about 347 motors of 4,813 H.P.

M. R. Picou asked M. Laffargue if the prices named include both *the expenses of the sinking fund and the expenses of administration*; he also said that it is not possible to establish any comparison as to cost price with distributions possessing only a concession of short duration in order to ensure the sinking fund.

M. Laffargue replied that these particulars are given; it is quite evident that no comparison is possible between concessions whose respective durations are 40 and 18 years.

The President then read out the results of the elections. The candidates elected were as follows:—

President (1899—1900), M. Violle; vice-presidents, Messrs. Olérac and Monnier; secretaries, Messrs. Abraham and Grosselin; treasurer, M. L. Violet; Members of the Committee: Messrs. Blondel, Blondin, Bouchard, Chammat, Desrosiers, Ebel, Gaiffe, Gauthier-Villars, Ch. Ed. Guillaume, Cl. Krebs, P. Laporte, A. Larnande, Margaine, Poincaré, Radiguet, De Romilly, G. Lautter, J. Voisedat; Members of the Committee of Accounts: Messrs. Armengaud, jun., A. Berthon and G. Masson.

Dr. D'Arsonval then thanked the Society for the honour that had been conferred upon him by electing him president, and he invited M. R. V. Picou to succeed him.

M. Picou asked permission to postpone until the next sitting the customary speech, and the meeting then broke up.

ELECTRICITY IN WARFARE.

The establishment of the Electrical Engineers Volunteers Corps in this country has led to steps being made in the same direction by the United States. A year or so ago when there seemed some likelihood of our being brought face to face with the army or navy of some other nation, the idea of the English electrical corps was born. Since then there has been much organisation work to be done, but though this is in an advanced state we should question whether the corps would be ready for the field within a few weeks if required. Now, however, that America is in a state of actual warfare with Spain, and requires, we suppose, all her forces to be ready within a very short space of time, there is a somewhat similar movement on foot in that country. Over seven years ago the attention of the U.S. was forcibly drawn to the advisability of forming such a corps, and if advantage had been then taken of the warning, the States would probably by this time have possessed a well-equipped body ready for all emergencies. There is no doubt that the Hispano-United States conflict will teach many lessons in warfare to both countries, though what the result of the affair may be it is unwise to attempt to conjecture. But in the matter of electrical engineer volunteers, the States may perhaps regret that steps were not taken earlier instead of waiting for us to set the example. However, at past the eleventh hour, Captain Eugene Griffin, U.S.A. retired, the first vice-president of the General Electric Company, has organised an auxiliary corps of electricians and electrical machinists, which will serve in the army or navy, or both. The engineer corps of the army has been short of electrical experts, whose services have been in great demand in the preparation and planning of submarine mines and torpedoes. Captain Griffin recognised this deficiency of skilled workers, and, with the permission of the Secretary of War, formed his plans, and has carried them out to success. He has, according to our New York namesake, obtained the names and the day and night addresses of a large number of skilled workmen in the employ of the General Electric, Westinghouse, and other electrical concerns in New York and the New England States. This information was sent direct to General John M. Wilson, U.S.A., chief of the engineer corps, who now has it on file. A number of these volunteers have already been at work in New York Harbour, Boston, and Philadelphia. Later news says that in less than a week Captain Griffin enrolled over 1,000 men.

Our contemporary, in a recent editorial, remarked that ultimate success in both land and sea practice depends very largely upon the electric current in one form or another. The preparations being made by electrical engineers and manufacturers are briefly mentioned.

In the first place the government has purchased thousands of miles of submarine and underground cable and other kinds of wire. These conductors are to be used for connecting and operating submarine mines and torpedoes, for establishing means of communication between the coast defence fortifications, and for feeders to supply current to the searchlights located at advantageous points along the coast. Nearly all the large wire manufacturing companies were at the beginning of April working their plants day and night, and the orders of many of their regular customers had to be side-tracked on the patriotic understanding that the government's needs at such a time must take precedence. One wire company was ordered to manufacture all the cable of a certain type it could turn out by a specified date some months in the future.

There was great activity in the manufacture of searchlights, large orders being received. In this connection, it is interesting to note that central stations located near the Long Island coast, such as the Edison Company in Brooklyn, have arranged to supply all the current required to operate searchlights on the fortifications in their vicinity. Electricians familiar with setting and connecting submarine mines were in great demand. The army engineer officer in charge of the fortifications in the vicinity of New Orleans has made a request for as many experts as can be spared. The General Electric Company furnished a party of 20 experts to be placed at the service of the government for torpedo work and connecting up searchlights. The Western Union and the Postal Telegraph companies have formed two corps of expert telegraphers composed of 50 men each, equipped with pocket kits of tools.

The telephone companies along the coast have also made arrangements to assist the government in every possible way.

The later technical journals to hand by this week's mail are, of course, well stocked with news regarding electrical work in connection with the war.

Mr. Frank J. Sprague, of the Sprague Electric Company, is organising an emergency corps of electricians and electrical engineers to work in conjunction with the State Naval Reserve.

The Westinghouse Electric Manufacturing Company is shipping large quantities of generators, motors, dynamos and wires to the Brooklyn Navy Yard, for use in the installation of electric power and lighting plants on board the merchantmen, old monitors and coasting steamers being equipped by the government.

President McKinley has issued an executive order establishing the ratings of chief electrician, electrician first class and electrician second class, to be taken from civil life for service in the Navy. They will be required to pass a physical and professional examination at the New York Navy Yard.

Prof. Elisha Gray has been describing in the *Times-Herald*, of Chicago, a very ingenious arrangement by which the telautograph could be adapted in coast and harbour defences for locating the exact position of an enemy's vessel. By means of suitable electrical connections the device could serve as a range finder.

The government is, of course, giving special attention to telegraphic communication along the coast, and to and in the West Indies. The *Western Electrician* says that it has arranged for the establishment in one day's time of its own telegraphic system for secret service along the entire Atlantic coast. The whole coast will be divided into districts. The government intends to build houses on the beach, where naval reserve officers will be stationed with telescopes to keep watch and report to headquarters in the city all ships sighted at sea. The system will have connection with the Western Union telegraph wires and the long-distance telephone. Three operators will be stationed in the main office in Savannah, which will be in full charge of the office and the signal corps. The Savannah office will be in direct communication with the Navy Department at Washington.

In New York, Boston, and other harbours, the work of connecting the coast defences for electrical communication is proceeding with energy. As a result of representations made by Capt. James Allen, signal officer stationed at Governor's Island, to General A. W. Greely, chief signal officer, of the absolute necessity of the expenditure of more than $25,000 in the telephonic and telegraphic connections between the fortifications in New York harbour, New York will get $25,000 more to complete this work according to the original plans. Boston will get about $10,000, Philadelphia about $5,000, and Washington, Baltimore, Newport, and Portland, Me., will also get increased appropriations. The total increase for the Department of the East is $96,000. This increased appropriation will make it possible to do an especially important work. All coast fortifications are provided with range finders for the purpose of determining the distance from the fortification of an enemy's vessel. These, if they are to be used effectively, must be supplemented by telegraphic apparatus, to enable the man in the tower to telegraph to the gun pits the range of the approaching vessel. The majority of the range finders in the fortifications are now so equipped. Every one will be equipped within 30 days.

One serious problem is the possible interruption of cable service in the West Indies. An arrangement was recently made by which the United States and France will co-operate through their ministers at Denmark in the establishment of a public cable station on the Danish island of St. Thomas. The cable is owned by a French company, but its use has become of vital importance to the United States Government, owing to the possible base of naval operations in the Leeward Islands Secretary Long was particularly desirous of having this cable arrangement effected. As a result of conferences a dispatch was sent to the United States minister at Copenhagen asking him to secure the consent of the Danish Government, and at the same time the French authorities arranged to have their minister at Copenhagen exert similar influences. With the Leeward Islands, of which St. Thomas is a centre, as the probable centre of any naval operations which may result from the present crisis, it is recognised as of vital importance to secure cable facilities not controlled by Spain. At present the cable line touching at Puerto Rico, and subject to Spanish control, is the only means of communicating with these islands. The French cable lands at St. Thomas, but the station is merely for testing purposes, and messages are not received or delivered. It is now proposed to have this station turned into a regular bureau, in which case the government could be brought into close cable communication with any naval rendezvous there.

It is stated that the Western Union and the Postal Telegraph Companies have begun to organise corps of skilled electricians, whose services are to be offered to the government. The Postal Telegraph Company has already organised three companies of 50 men each in New York and an equal number in Boston for this service. The particular work expected of the men is the laying of submarine cables and connecting them with submarine mines and torpedoes. Every man in each company has been provided with a kit of tools, which, under orders, he carries with him day and night. The men have been informed of the service expected of them, and they have been informed that they will draw their salaries from the company as well as their pay from the government.

Lynde Bradley, of Milwaukee, has devised plans for the use of the X ray on board of war vessels and on the field. Mr. Bradley says that while it would be a simple matter to bring the X ray into use on a warship, considerable difficulty would be attached to the introduction of the apparatus on the field. A small outfit would have to be mounted on wheels for field use. The apparatus would, however, be much lighter and more portable than may be imagined, and his field apparatus could be finished in a week. The great help that the X ray would be to surgeons lies in the quick method of locating a bullet or splinter in a man's body, a fracture of a bone or other serious injury.

It is said that the government has practically closed a contract with the General Electric Company for eight 400,000 (projected) candle-power searchlights with dynamos, to be set up in the fortifications in New York harbour. This order will be supplemented in a short time by one for several more to be placed elsewhere.

The largest searchlight that had a place on the top of the manufactures building at the World's Fair has been brought from Sandy Hook to Fort Monroe, Va. It will illuminate Hampton Roads from shore line to shore line.

HIGH RESISTANCE INSULATION.*

By REGINALD A. FESSENDEN.

In laboratory apparatus in many cases, for instance, with electrometers and resistance boxes, we need as high ohmic resistance as it is possible to get. Here, however, we are met by the fact that the two substances most commonly used, *i.e.*, hard rubber and glass, are among the poorest insulators known for this class of work.

Rubber is very objectionable from the fact that whilst it presents a nice bright appearance when new, it contains sulphur and is very easily oxidised, especially when exposed to light. A film of sulphuric acid is thus formed on the surface, and if the tongue be applied to a piece of rubber which has been in use for some time the taste of the acid is very strong. I have seen the top of a Wheatstone bridge, supposed to be capable of measuring accurately to one part in 5,000, in which the total length exposed to leakage, divided by the average distance between which leakage could take place and the average voltage was only ·008, with the top so acid that the tongue could hardly be allowed to touch it.

As a rule it is very hard to remedy this; rubbing the surface does no good as the acid extends in to some distance. Rubbing with cigar ashes is advocated by some, but I should fancy it would be almost impossible to remove the last traces of alkali. The method used by the writer is to steep the rubber in warm 10 per cent. caustic soda, then in warm distilled water, frequently renewed, then drying in the dark quickly and rubbing with pure paraffin, treated as described under paraffin, then polished while warm. This does good for a time, until the paraffin takes up dust.

For rods, a good way is to treat as above and coat half an inch thick with paraffin; then run over the rod with a wooden die and cut a thread in the paraffin. Run over the thread about once a month, and good results will be obtained.

With bridges, however, it is impossible to remove the top, and the only thing which can be done is to keep them covered up from light.

Rubber has also one other disadvantage, in that it does not show dirt, and where rubber comes in contact with copper it is apt to rot.

Glass is very bad because the alkali in it has a great affinity for moisture. The alkali is slightly soluble, and hence it is the custom with analytical chemists to boil all beakers used in exact work for several days before using, so as to get the soluble alkali and silica out of them. When possible this should be done with the glass of electrical apparatus. Another very serious trouble is that the angle of contact between water and glass is zero, so that when a drop of water is placed in the middle of a pane of clean glass it immediately spreads all over it in a thin film. This method is used by chemists to determine when a glass is clean. Nothing much can be done with glass but to keep it dry. Sulphuric acid is generally used, but it sometimes, if allowed to get dust in it, gives off vapours which condense on the sides of the apparatus. This, however, does not often happen.

Evidently we need some substance of high ohmic resistance, and one which water will not wet. Boys, who has earned the thanks of electricians for his happy discovery of an almost perfectly elastic fibre, has given us also, as he himself has pointed out, such an insulator in quartz. Dip a thread of glass in water and lay it between the knob of a charged electrometer and the ground, and the leaves close almost at once, the whole fibre being covered with a film of water. Treat a quartz fibre similarly and the water slides off it, or remains in little drops, each separate from its fellow, and the insulator is apparently as good as the air itself.

Quartz should, therefore, be used as much as possible in electrical instrument work. It can be melted in a powerful gas flame furnace, and though it can never be melted down free from small bubbles, these make no difference except in appearance. It is, however, possible to obtain glass which contains no alkali, and resembles quartz in that is not wet by water. Such a substance is Faraday's borate of lead glass, as he himself points out. This is, however, too brittle for most work, but by an admixture with silica a glass could no doubt be made which would be perfectly satisfactory. If some glass manufacturers would take up this question and furnish us such a material for electrical instruments, the greater part of the present annoyance met with in making delicate experiments would vanish. It would not leak, would show dirt, could be readily cleaned, and would be free from one of the great disadvantages of rubber, *i.e.*, a large coefficient of expansion, which is always making trouble by bending terminals of resistance coils, thus changing their value and sometimes opening the circuit.

It is also probable that a fine grade of porcelain would be a great benefit to the electrical profession, if coated with a good non-alkaline glaze.

For insulating the coils of resistances it is doubtful if we

* Extract from a paper read before the American Institute of Electrical Engineers. From an incomplete advance proof.

have any good solid material. For paraffin cannot be used, as its expansion and contraction are so great that large pressures are put upon the wire and the resultant strains change the resistance. It might be easy enough to prevent the strain on the first solidification in a way similar to that devised by Rowland for cementing flat mirrors without buckling them, *i.e.*, by mixing a little glycerine with the beeswax; the glycerine not dissolving in the beeswax makes it act like a viscous fluid, *i.e.*, deform under the action of infinitesimal forces in time. The glycerine, however, finally works its way out like zinc in a resistance alloy (as first pointed out by Mr. Weston), and if a similar method were used with the coils, it would still be subjected to strains on change of temperature. Another objection which has been made in England is that paraffin absorbs moisture. It is possible that this is due to the dissimilar methods of producing American and English paraffin, as I have never had to complain of this, except, of course, when cold paraffin was placed in saturated moist air. The insulation resistance of paraffin seems, however, to be markedly increased by the treatment mentioned below. The great objection to paraffin is its tendency to collect dust. Shellac has been recommended, and since the coils are in the dark, the material will oxidise but slowly, and if care be taken to use pure alcohol for a solvent, and not denaturised spirit (which sometimes contains conducting impurities), has a very high resistance when dry. Some forms of Japan lac seem to remain flexible permanently, as, for instance, the sample *a* (composition unknown), which is 10 years old.

Oil is sometimes used for resistance coils, and this is without doubt the best method, since the great point in the use of resistance coils is to know their temperature. The writer's experience with manganin and constantin, as practical laboratory standards, has been unfortunate, and he has hence decided to use only standards of pure lead run into glass tubes, and kept in water. The reason is that, other things being equal, the most sensitive Wheatstone bridge is that which takes the greatest current without appreciable heating, and in the ordinary form of resistance coil, a very small current will heat the interior up to such a temperature, as to alter the value. Moreover, if the coil is of a material not affected by such changes of temperature, it (with our present alloys) will have a larger temperature coefficient, and as the temperature of the interior of the coil is not known, this introduces another uncertainty. With the oil mounting, however, this is all done away with, and pure oil has a very high resistance for low voltages.

For condensers and induction coils it is not only necessary to have materials of great ohmic resistance and of great dielectric strength; they must also be perfectly pure, and free from admixture. For the first two properties there is nothing so good as paraffin, when properly used, all compositions such as beeswax (cerotic acid), &c., being quite inferior in both respects. Paraffin, and what is practically the same thing, pure ozokerite, will stand, according to the tests of Mr. Chesney, which I had the pleasure of witnessing, at the rate of 500,000 volts per inch. This I have confirmed up to 600,000 volts alternating. Most substances, such, for instance, as glass, are at once cut out from consideration, from the fact that they have too much electrical absorption, and heat when subjected to a fluctuating voltage.

We must have an electrically homogenous dielectric, *i.e.*, one of the same specific inductive capacity all through. This

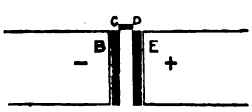


Fig. 5.

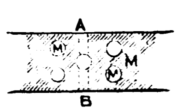

Fig. 6.

is for two reasons. First, because if we have a dielectric, A, between two charged conductors, the introduction of a dielectric of greater specific inductive capacity, even if of infinite dielectric strength and ohmic resistance, will cause A to break down. To take a numerical case—suppose we have two plates, 1 cm. apart, and attached to the terminals of a 10,000 volt A.C. dynamo (fig. 5). Suppose the dielectric, air, to support 50 per cent. more than this pressure. Introduce two plates of glass of $K = 8$, each $\frac{1}{4}$ cm. in thickness. Since the voltage divides itself up inversely to the capacitance, we will now have 8,889 volts between C and D. This being at the rate of 17,778 volts per cm., and as it only supports 15,000, we will get a spark between C and D at every reversal of the voltage, which will quickly heat the glass and make it conduct. The full potential of 10,000 will then be between C and D, and a regular arc will form. Thus we see that the introduction of a good insulator will, in all cases where an intermittent or alternating voltage is used, have the paradoxical effect of weakening the insulation, unless the whole space is filled up with the material. This weakening is not generally apparent at once, as the spark takes some time to eat its way back, and this explains why many induction coils only last for a few years of operation.

Another cause is that treated of by Poisson, Clausius and Maxwell.* This is, that layers of dielectrics of different

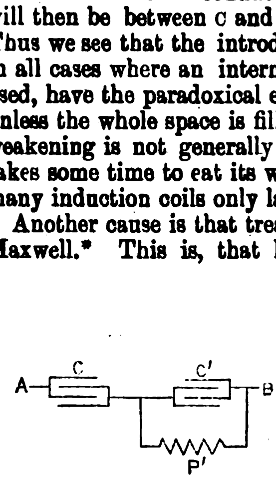

Fig. 7.

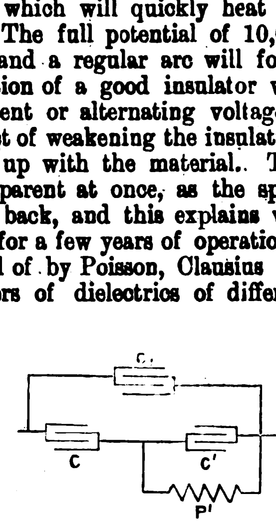

Fig. 8.

capacities and resistances show electrical absorption, and this theory has been proven experimentally by Muraoka, who showed that by taking two fluids, neither of which showed absorption, a layer of one on top of the other did do so. Maxwell treated the general case. It has, however, been treated in a more specialised way in *La Lumiere Elec.*, in 1891. In this paper are brought out the following points:—

1. A dielectric, as in fig. 6, containing conducting particles of water, for instance, may be considered as an arrangement of condensers and resistances in series and shunt with each other. Two cases, shown in figs. 7 and 8,

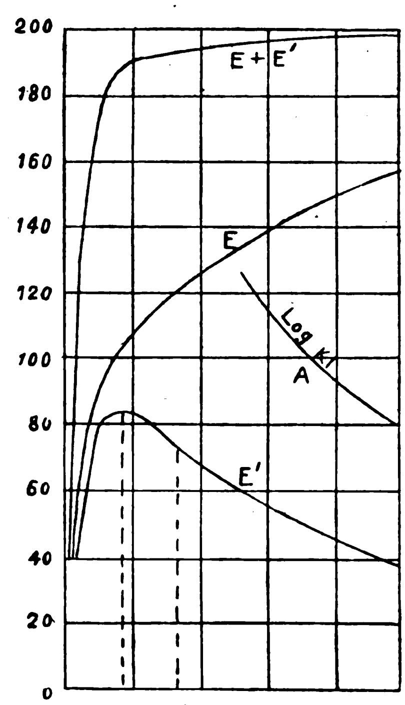

Fig. 9.

are worked out, and fig. 9 gives the curve of charge in the cases of fig. 7; E is the voltage on the condenser part, and E′ that on the condenser and resistance.

2. A condenser can show large residual charge, though its true ohmic resistance is infinite.

3. With dielectrics showing absorption, there will be found some discharge time at which the amount of discharge will be constant at all temperatures.

* "Elec. and Mag.," Vol. I, Chapter X.

4. Why in some tests insulation seems to be lower with higher voltages.
5. Why the presence of conducting particles increases apparent capacity.
6. That to get true ohmic resistance of most dielectrics, voltage must be kept on for a long time, even for days.
7. Why Siemens's method of taking the rate of loss of charge by electrometer does not give correct results.
8. That specific inductive capacity of such dielectrics can only be determined by rapidly alternating currents. This possibly explains an effect noticed by the writer many years ago, *i.e.*, that an A.C. static wattmeter immersed in water did not give anything like the torque it should have if the true value of K for water were 80.
9. The importance of getting out the last traces of water in gutta-percha and paper when used for cables.

(*To be continued.*)

A NEW INTERRUPTER FOR INDUCTION COILS.*

By V. CREMIEU.

In consequence of the working of the interrupters used in Ruhmkorff coils, the induced electromotive forces, of opposite nature, are not equal in absolute value; they may be represented by the curve (fig. 1) in which *e r* shows the electromotive force induced on the breakage of the primary

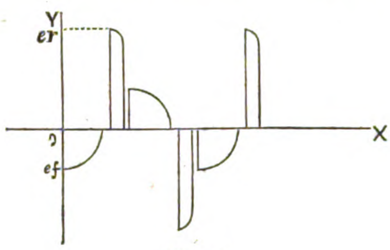

Fig. 1.

circuit and *e f* that which is induced on the closing of the circuit. This difference, which is considerable, is productive of much inconvenience in the use of induction coils.

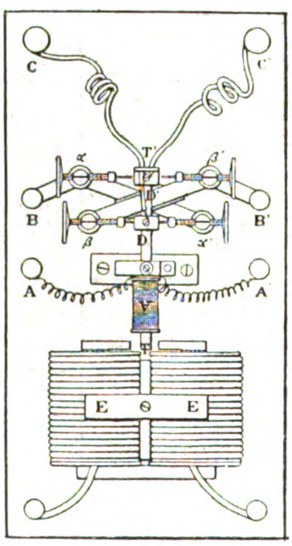

Fig. 2.

By sending into the electro-magnet an alternating current, we can, for low voltages, overcome this inconvenience; but this method cannot be used when we wish to obtain sparks several centimetres long.

I have solved the question by means of the little apparatus I am about to describe.

An electro-magnet E E′ is excited by an alternating current (fig. 2). Between its two poles oscillates the end of a rod T T′, movable at O, on an axis perpendicular to the plane of the figure. The part O T is of soft iron and the part O T′ of ebonite or some other insulating material. On the part O T is wound a little bobbin, V, traversed by a continuous current. From it we get at T a determinate magnetic pole. When the alternating current traverses E E′, an oscillatory movement is imparted to the rod T, the period of which is equal to that of the alternating current. On the part, O T′, of the oscillating rod are fixed two platinum plates, D D′, connected by two flexible wires with the terminals, C C′.

During the movement the two plates, D D′, come successively in contact with the terminals, α β, α' β'; these are connected two by two with the arrival terminals, B B′, of the inductive current; the arrangement of the apparatus shows therefore that if, for instance, the + pole of the current is at B, and the − pole at B′, the current which circulates between C and C′, in consequence of the successive closings of the current due to the movement of the rod, will go alternately from C to C′, and from C′ to C; the nature of the current between these two terminals will be reversed between two successive breaks. We see, therefore, that the induced electromotive forces of opposite nature (fig. 3) will,

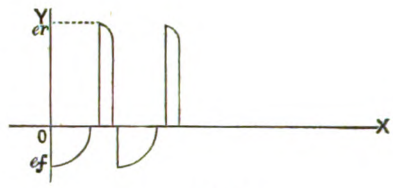

Fig. 3.

at each movement, be the sum of two quantities that are always the same, and of the same sign. They will therefore be equal in absolute value.

The apparatus works very well. For an intense inductive current, the contacts, α α' and β β', and the part O T′ of the rod should be immersed in some suitable liquid.

The only drawback which can, however, easily be provided against, is a somewhat considerable loss of energy; in order to obtain sparks of the same length, it is necessary to send into this interrupter a current of double the electromotive force required with a Foucault interrupter. The apparatus is, moreover, reversible, *i.e.*, if we connect the terminals C C′ with the two poles of the alternating current, a derivation

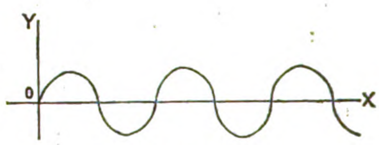

Fig. 4.

of which excites the magnet, E E′, we get between the terminals, B B′, a reversed alternating current. If the current arriving at C C′ is represented by the curve shown in fig. 4, that received between B B′ will be represented by the curve shown in fig. 5.

But we must avoid producing the successive breaks at the

Fig. 5.

moment when the periodic electromotive force has its maximum value, or even a large fraction of this value.

A very simple arrangement enables us to produce the breaks at the moment when this electromotive force is *nil*: the screws of the contact terminals, α α', β β', are hollowed out in the direction of their axis, with a cylindrical cavity (fig. 6). At the bottom of this cavity is a very flexible spiral spring and a cylindrical piece of platinum, T P,

* Note presented to the Académie des Sciences, February 17th, 1898, and reproduced from *L'Electricien.*

in the form of a plunger, the rod of which, T, would slip into a brass screw cap, C, screwing on to the end of the screw.

The rod T T′ being at rest (fig 2), the four screws are regulated so that they touch, without pressing, the contacts

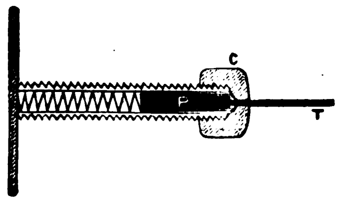

Fig. 6.

D D′, the end T being equidistant from the two poles of the magnet E E′.

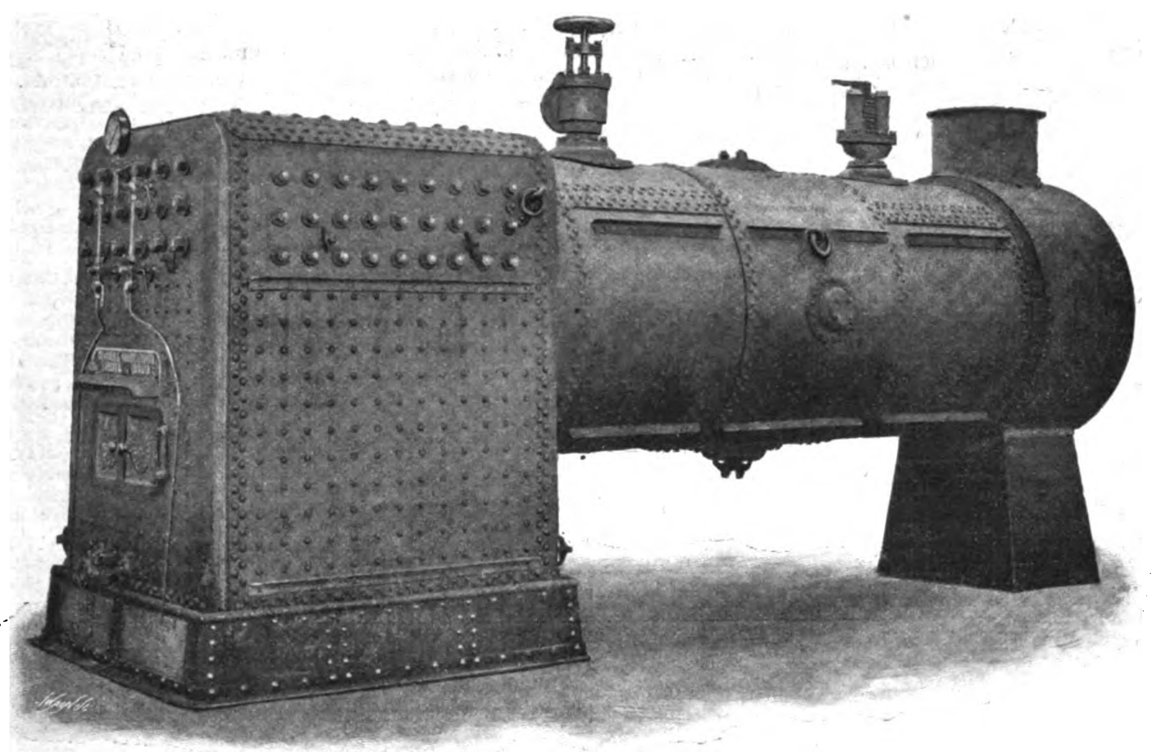
As soon as the rod T T′ oscillates, the contacts D D′ are drawn right and left, alternately repelling the plungers α β on leaving α' β', and then repelling α' β' on leaving α β.

If we observe, moreover, that the rod T T′ passes through its position of non-acceleration just at the moment when the electromotive force of the alternating current which excites E E′ is also *nil*, and that the breaks are made at this very moment, we see that there will be no break spark at α α, β' β'.

In practice, very feeble sparks are produced. The loss of energy does not exceed a quarter of the original energy.

BOILERS FOR CAPE TOWN ELECTRICITY WORKS.

Messrs. Clayton & Shuttleworth, of Lincoln, have supplied two large locomotive type boilers for the electricity works at Cape Town. These are of the type shown in the photograph and known as the "Belpaire." The boiler is constructed of mild steel throughout, and the fire-box plates are of a special quality in order to withstand high temperatures. The Belpaire type of boiler is claimed to offer great advantages in respect of the staying of the fire-box crown, as through stays can be used, which for large fire-boxes and high working pressures are thought to be better than girder stays, because they leave the top of the fire-box comparatively clear for cleaning purposes. There is also said to be a saving in weight. The scantlings on plates and stays are to suit the Board of Trade requirements for a working pressure of 150 lbs. per square inch. The extreme length of the boiler is 22 feet 6 inches, its width 6 feet, and the height, exclusive of ashpan and fittings, 7 feet 9 inches. The longitudinal seams are fitted with double butt strips, and all rivet holes are drilled in position. The main diameter of the barrel is 5 feet 6 inches. The barrel plates are $\frac{9}{16}$ inch thick. Front plate, throat plate, and fire-box casing $\frac{9}{16}$ inch. Tube plates $\frac{3}{4}$ inch, and the fire-box plates $\frac{9}{16}$ inch. The inside dimensions of fire-box are: Length, 6 feet $0\frac{9}{16}$ inch; width at top, 5 feet; width at bottom, 5 feet $3\frac{3}{4}$ inches; total depth, 5 feet $2\frac{1}{2}$ inches; depth to fire-bars, 4 feet $6\frac{1}{4}$ inches. There are 98 steel tubes in the boiler, each of 3 inches external diameter, 10 S.W.G. thick, and 12 feet $1\frac{1}{2}$ inch long between the tube plates. This includes six stay tubes, with nuts on each side of the tube plates. The total heating surface is 1,080 square feet, and the grate area 32·2 square feet. The guaranteed evaporative performance is 5,360 lbs. of water per hour. The manufacturers subjected the boiler to a hydraulic test pressure of 280 lbs. per square inch, and a steam pressure of 150 lbs. per square inch without any sign of leakage or any weakness.



AMERICAN TRACTION PLANT.

The *Street Railway Review* is grieved because an esteemed English contemporary expressed the opinion that there was a good field for British made electric traction plant in America. To send electric plant to America would savour of sending coals to Newcastle, says the *Street Railway Review* in its wrath, and it proceeds to give advice to Englishmen as to learning from American experience. We are not ourselves disposed to question the fact that American experience is very great in traction supplies manufacture. At the same time, we doubt altogether the conclusions drawn from the sale of American plant in England. In the first place, while Americans are busily engaged in cutting each others throats, or rather prices, we observe that they all, with one accord, keep an eye on the topmost brick of the high tariff wall they have built around the domestic cockpit. Americans can beat the world: they declare this to be their conviction. At the same time, all the world can see they have not got the courage of their convictions, and whether they could do so or not, they dare not face the world except from behind the high wall. Wisely or unwisely, business on this side is conducted with some idea of profit, and either because of this or because we are too slow in adopting cheapening devices and machinery, we cannot afford to sell the equipment of a car, including two 25 H.P. motors and all accessories, for £140, which is, we believe, the price at which American plant is sold to England. We are not informed as to whether American manufacturers can make a profit on these rates, nor are we told whether these low prices are available for American purchasers. Wherever we have investigated the relative prices of American goods at home and in England we have invariably found that the prices for identical goods were very much less in England, and the conviction has forced itself on us that England has the chance of buying a good deal of stuff at less than it can be bought behind the tariff wall. All Queen Victoria Street speaks to this conclusion. Protective tariffs always produce these results. Another instance is that English sugar users pay less for sugar than its makers in France or Germany. It may be that the overflow of American manufactures is alone sold here at such low figures. Whatever the cause, it is certain that American goods are not able to compete in the open market, whereby we mean not the neutral market alone, but the home market also. Americans themselves do not yet believe in their ability to compete on fair terms, or they would knock a brick or two off their 50 per cent. wall of tariffs—or is it 75 per cent.? a few per cent. makes no difference, however—and come out into the open. While we English are certainly likely to purchase a good deal of bounty-fed sugar and tariff-cheapened machinery for some time, we cannot agree with the *Street Railway Review*, that American factories can give us as good and enduring apparatus as we are likely to evolve at home. It is not as our contemporary supposes, a question of conditions, nor is it that English engineers decry American experience.

With an equal amount of experience, we venture to say that English traction plant will surpass that of American make. At present we have not the experience, and Americans take very good care that we shall not gain that experience by manufacturing for them. Our contemporary would retort that they know better than buy from such inexperienced people. We anticipate the retort, and would reply that they dare not give us the chance of selling, nor dare they offer their own public the chance of buying.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. Thompson & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

8,489. "Improvements relating to the electro-deposition of metal." H. W. Wright. Dated April 12th.

8,495. "Improvements in electric switches and fuses." J. McFarlane and Holland House Electrical Manufacturing Company, Limited. Dated April 12th.

8,528. "Process and apparatus for concentrating magnetic iron ores and bricking the same for market." B. J. B. Mills. (T. A. Edison, United States) Dated April 12th. (*Complete.*)

8,638. "Improvements in electric furnaces for the manufacture of carbide of calcium or other electro-chemical or electro-metallurgical products of the like kind." P. Determes. Dated April 13th.

8,645. "Improvements in telephone directories." J. D. Browning. Dated April 13th. (*Complete.*)

8,710. "Improvements in and relating to electrical incandescence lamps." J. R. Quain. Dated April 14th.

8,713. "Improvements in and connected with generators for electrical igniters in gas or like engines." B. McInnerney. Dated April 14th. (*Complete.*)

8,718. "Improvements in telephonic apparatus." M. Freudenberg. Dated April 14th.

8,735. "Improvements in telegraphic transmission over long submarine cables by Wheatstone's automatic apparatus." S. Roos and P. Biraghi. Dated April 14th.

8,823. "Improvements in or connected with drum apparatus for electric generators and motors." V. A. Fynn. Dated April 15th.

8,829. "An improved apparatus for counting telephonic conversations." F. Graf. Dated April 15th.

8,832. "Improvements in electricity meters." C. E. O'Keenan. Dated April 15th.

8,848. "Improvements in the method of and means for the electrical propulsion of railway, tramway and other similar vehicles." W. G. Heys. (J. J. Heilmann, France.) Dated April 16th. (*Complete.*)

8,856. "An improved method of intercepting dust arising from the commutator of dynamos." J. McLaren. Dated April 16th.

8,864. "Improvements in electric devices for theatrical purposes." M. Sanson. Dated April 16th. (*Complete.*)

8,901. "Improvements in or relating to electrostatic machines." L. S. A. Cohendet & Co., and P. Arohat. Dated April 16th. (Date applied for under Patents, &c., Act, 1883, Sec. 103, March 5th being date of application in France).

8,913. "A method of and means for transmitting electric currents through musical instruments to players or performers." H. B. Knoblauch. Dated April 16th.

8,920. "Improvements in trolley poles and standards for electric traction." Siemens Brothers & Co., Ltd., and F. Ayton. Dated April 16th.

8,927. "Improvements in electrical apparatus for gas lighting and other purposes." J. F. Bennett and W. Appleyard. Dated April 16th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. (*in stamps*).]

1897.

5,136. "Improved electric tan bark bath and apparatus therefor." J. J. Stanger. Dated October 9th, 1897. This relates to an improved tan bath for use against rheumatism, gout, &c. There is a bath filled with tannin solution, to which the electric current is supplied, so that the main conductor is in connection with the electrodes. These electrodes are carbon and do not contaminate the tannin solution. They are inserted in slotted wood frames placed in bath, and are easily removable. Upon a plate there are placed a rheostat, a reversing switch, a current meter, and a bell in such a manner that these apparatuses which control the current at will are easily accessible from the bath. 3 claims.

4,183. "Improvements in electric incandescent lamps." C. S. Dolley, R. Hawkins, T. M. Lightfoot, H. P. Goodwin. Dated October 16th, 1897. This consists of an electric lamp, which has an incandescent filament compressed between two non-conducting plates of mica one or both of them being transparent. The air has been exhausted from between these plates, which are set in a hermetically sealed boundary frame. The carbon conductor is furnished with platinum wire connections. 3 claims.

9,173. "An electro-therapeutical lamp." R. I. Mayer. Dated October 16th, 1897. This consists of a handle, on end of which there is filled an incandescence lamp within a suitably arranged reflector, through the core of the handle pass the conductors. 1 claim.

19,035. "Improvements in electrolytic apparatus." H. Sefton-Jones. (A communication from E. Balbach.) Dated October 16th, 1897. This consists of a cathode case composed of a trough having its bottom divided in two portions, one of which is horizontal. The other portion sloping down and connecting the horizontal portion throughout its length. It is provided with a cathode plate and an anode suspended therein, arranged to cover the horizontal portion of the bottom only. The anode case is composed of an exterior frame which has a grated bottom, and an inner frame fitting into the exterior case, with a filter cloth bottom. Instead of one anode case there may be a series, arranged transversely side by side. 5 claims.

20,041 "Improvements in metal for telegraph and other poles." G. W. Glazier. Dated October 16th, 1897. This consists of a pole to the end of which is secured segmental metal base sections by means of bolts; the lower ends of these sections are made outwardly flaring, and are provided with a series of perforations through which the earth is rammed after these sections have been placed in a cavity in the ground. On the outside of these sections are strengthening ribs which, besides serving to increase the strength, also in a measure conceal and protect the heads and nuts of the fastening bolts. 2 claims.

ELECTRICAL REVIEW.

VOL. XLII. MAY 6, 1898. No. 1,067.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEKKAY, LONDON." Code A B C.

Telephone No. 938 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

ELECTRICAL DEVELOPMENT.

WE notice in the columns of an American contemporary * an admirable little homily addressed by Mr. W. D. Weaver to those terribly optimistic people who, unsatisfied with all that modern electrical science has done for them, are ever anticipating new discoveries of transcendental magnitude, and accept with all the credulity of profound ignorance those scientific fairy tales with which the non-technical press is ever ready to supply them. This attitude arises in part, as Mr. Weaver points out, from the air of mystery with which in the popular mind all things electrical are specially enshrouded. The achieved results of electrical science have struck the popular imagination, and ignorant of the bounds set by the nature of electrical energy, it runs riot in the region of the impossible. To-day the public hears with respectful admiration that one of the Grand Lamas of the electrical cult is ready, nay, it is whispered, anxious, to annihilate whole battalions *en bloc* with the aid of an electrified squirt; to-morrow, that the electric fluid has at last been tracked down and bottled, and can be supplied in various colours, and at the most reasonable prices, for the cure of diseases of diverse kinds. The public finds no difficulty about the reception of these stupendous yarns, and like the young gentleman in fiction, asks for more! Of the unknown and the mysterious, it argues, all things may reasonably be expected.

As a matter of fact, however, the theory of electricity is as firmly established now as are the theories of light and heat, and far more so than that of gravitation, the most familiar of all the forces of nature, and at the same time the most incomprehensible. The time is yet to come when anything even approaching a satisfactory explanation can be given of the fact that a stone released from the hand falls to the ground. We are not, however, always anticipating revolutionary discoveries in thermo-dynamics, optics, or mechanics; we have a distinct and practical idea of the limits of probable development in those sciences, of the boundary between the possible and the impossible.

Moreover, there are limits which we can discern even in the absence of a perfect knowledge of the ultimate nature of electricity. We make our dynamos and transformers now with an efficiency of about 95 per cent., leaving small room for improvement when theory goes still deeper into the nature of the medium we work with. The uncertainty we may feel on such subjects as the dissociation of electrolytes and the migration of ions is not incompatible with a practical working knowledge of electro-chemical equivalents, the corresponding thermo-chemical equations, and armed with this knowledge we are able to turn a deaf ear to the wiles of the primary battery promoter in the certainty, much to be regretted, that apart from the solution of the great problem of the direct conversion of the energy of carbon into electrical

* *American Electrician*, reprinted from the *Annual Journal* of the Brotherhood of Electrical Workers.

energy, no revolutionary change in the cost of production of the latter can be expected. The solution of this problem means an extension of the life of our coalfields of many centuries, revolutionary changes in scores of established industries, the disappearance of such evil-smelling anachronisms and architectural monstrosities as gas works, and incidentally, the enriching of its discoverer beyond the dreams of avarice; but it may well be that our coalfields will be exhausted, and, perhaps, our spendthrift race with them, before the realisation of that great idea.

Mr. Weaver discusses two other attractive problems to which it has been thought that electricity might furnish a solution—the production of light without heat, and the transmission of energy across space without the use of a conducting wire. Much was hoped from Tesla's work on the former subject, but little practical result has been achieved. There is no prospect of the direct production of currents having a frequency of even 4×10^{14} periods per second, the radiation from which would be just visible to the eye as dull red light. The smallest wave length reached even in the oscillatory discharge of microscopic condensers is measured in centimetres instead of in their hundred-thousandth part, and it is only by molecular impact, as in a vacuum tube, that vibrations of a sufficiently rapid order, unaccompanied by heat, have been obtained.

The problem of the transmission of energy across space has recently been brought vividly before the mind in connection with the Marconi system of telegraphy. There is something singularly fascinating in the idea of the Morse key ticking away its message in the room at Bournemouth,* and the printing instrument over at the Needles recording the words just as certainly as though a cable linked the instruments together. But it is a far cry from this achievement to the transmission of energy for power purposes across space. Even the small amount of energy required for the printing instrument is not transmitted, only the infinitesimal quantity required to operate the coherer, which serves as an almost incredibly sensitive relay. The energy from the transmitter is scattered in all directions through space, and the waves can only be gathered into a parallel beam with difficulty and with considerable loss. As yet, moreover, we have no means of generating this particular form of wave energy in sufficient amount to serve any practical purpose, quite apart from the difficulty of transmitting it when obtained. It seems likely, therefore, that we shall have to put up with copper mains, and the C^2 R losses contingent thereon, for some time to come, in spite of the advantages that wave motion in the ether seems to offer as a practically wasteless mode of transmission.

The American Iron Trade Prospects.

The *Scientific American* states that from four of the Lake Superior iron mines, viz., the Marquette opened in 1856, Menominee opened in 1880, Gogebic opened in 1884, and the Mesabi opened in 1892, there have been produced over 98 million tons of ore. The last mine alone produced in five years over 8 millions of tons, one half of which ore is of over 60 per cent. iron, and contains only 0·06 per cent. of phosphorous. In this mine there is in sight or indicated some 400 million tons, or sufficient at present production for 50 years. As all the above mines must continue at present rates if the present rate of iron manufacture is to be maintained, there will need to be a vast further body of ore if America is to keep the lead for an indefinite period. There appears good reason to endorse Mr. Jeans's prediction that the centre of iron production may yet shift to other countries, as, for example, Australia. But for many years to come the continent of North America is likely to increase its output of iron. It is still considerably behind the production of the equal area of the European Continent; indeed, has only just exceeded the production of England, a small section of Europe, about half the size of a moderate American State. The advantages of the Lake Superior ores generally are their great accessibility, being often surface mined and well placed for cheap working; they are very rich in iron and low in phosphorous, and so are eminently Bessemer ores, and the ore beds are of great extent. Some samples assay over 67 per cent. iron, and out of nine grades of ore in the Vermilion ranges none went less than 60 per cent. Phosphorous is very rarely over 0·1 per cent. On the Mesabi range a steam shovel can load 500 tons per hour at 7½d. per ton on the cars, and at times it is claimed cars have been loaded for 5d. per ton. Evidently there will be no scarcity of iron in the lifetime of anyone living to-day.

Economy of Hot Feed.

Mr. MacFarlane Gray has again drawn attention to what Mr. Kirkaldy first discovered, that it pays to heat feed water with live steam drawn from the same boiler into which the feed is being put. Mr. Gray only attempts to explain it by increased mobility of water. Our contemporary, the *Electrician*, attempts a more scientific explanation, that the economy due to this live steam feed heating is due to the better thermo-dynamic efficiency of heat transmission from fire to hot water than from fire to cold water. The larger temperature drop in the case of cold water is useless. Heat ought to be transferred as near the maximum temperature as possible. If this feed-heating question can be explained thermo-dynamically, what a chance the men have missed who, like Mr. Gray, are thermo-dynamicians and yet have failed to fit the practice to theory. Are we again to see a thermo-dynamic theory fitted to a proved practical fact, for there seems now no reason to doubt the facts. It is an unfortunate shortcoming of most scientific men that they are not possessed of the ability to foresee facts from their theoretic knowledge, though they are very ready to assert themselves in picking the flesh off the skeleton and exposing the hard dry bones beneath. Practical men would be glad of a few X rays of scientific research to show the bones in the living creature without the process of stripping off the flesh. It has been held that the only duty of the furnace ought to be to supply the latent heat to the water in a boiler. To a very large extent this has been followed in north country practice where heat of low degree, otherwise going to waste, is employed to heat the feed in the economiser or flue feed heater, and this may account to some extent for the good evaporative results obtained there from plain boilers.

Institution of Electrical Engineers.—Last night at the ordinary (extra) general meeting, held at the Society of Arts, a paper was read on "The Prevention of Interruptions to Electricity Supply," by Mr. Leonard Andrews, Associate.

* Electrical Review, Vol. xlii., p. 538.

CARBON BRUSH-HOLDERS.

By ERNEST KILBURN SCOTT.

Part I.

(*Concluded from page 564.*)

The other more widely known but, perhaps, little understood method, is by the use of a solid carbon block, or, better still, by a multi-section carbon brush. Fig. 4 shows such a

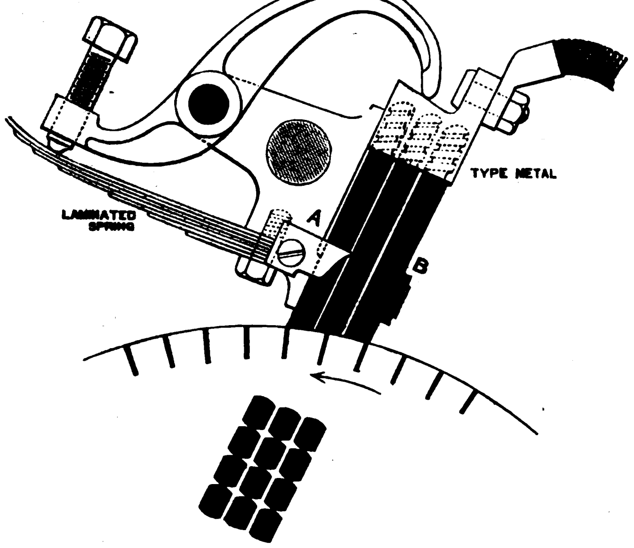

Fig. 4.

brush and holder designed by the writer, from which it will be seen that the brush is made up of the scrap ends of ordinary arc lamp carbons bunched together, as shown in the section A B. Type metal is cast round them at one end, and in order to get the metal to hold properly they are spaced about $\frac{1}{16}$th inch apart, thus giving the multi-section brush. When the carbons are worn away the type metal can be melted off and used over again. In connection with this holder it should be noted that the tangential pressure keeping the brush firmly against the holder casting, can only be fully utilised when the armature is revolving in the direction of the arrow.

The immediate effect of increasing the resistance in the circuit of the short-circuited coils may be explained as follows: When working at full load the coil under short circuit must be in a field of considerable strength, in order that the current may be properly reversed. It follows, therefore, that if the load is allowed to fall off without the lead being proportionately reduced, the field will naturally tend to cause an excessive flow of current through the short-circuited coils. This is where the above-mentioned extra resistance comes in, as a check against the rush of current and consequent arcing and waste of heat.

Another point in connection with the design of brushes and commutator is, that the interval of short circuit, or, in other words, the width of a brush, has a marked effect upon sparking. On a given dynamo, with single-wound armatures, for example, commutation can be more easily effected in a strong field if the brushes cover several segments instead of only one. One may therefore argue that a high induction density in the armature is not only a good feature because it reduces the weight of copper and iron per kilowatt output, but that it also allows of a thick brush being used, or, in other words, it shortens up the commutator. Where currents running into thousands of amperes have to be dealt with, the advantage of this is obvious, for even with double or quadruple wound armatures the cost of the commutator is a heavy item in large output machines.

When a commutator appears to work well at first, but afterwards becomes badly scored, it will generally be found that it is caused by the proportions being such that the contact surface between the metal brush and the receding segment of the commutator decreases more rapidly than the current which is flowing; the result of this being that too big an amperage is crowded into the surface of the brush, causing it to fuse and stick. It is this fusing of the metal (shown when it is very pronounced by yellowish sparks) that scores the commutator, the small bluish sparks which spit off from the outer edge of the brush being comparatively harmless. Carbon brushes being infusible prevent this trouble.

Part II.

As the designs of brush-holders are very numerous, it will be necessary to confine the purely descriptive part of this article to a few typical types. Most brush-holders intended for metal brushes have the one great fault of not allowing the brush to be automatically set up by a parallel feed. On many holders, for example, it will be noticed that as

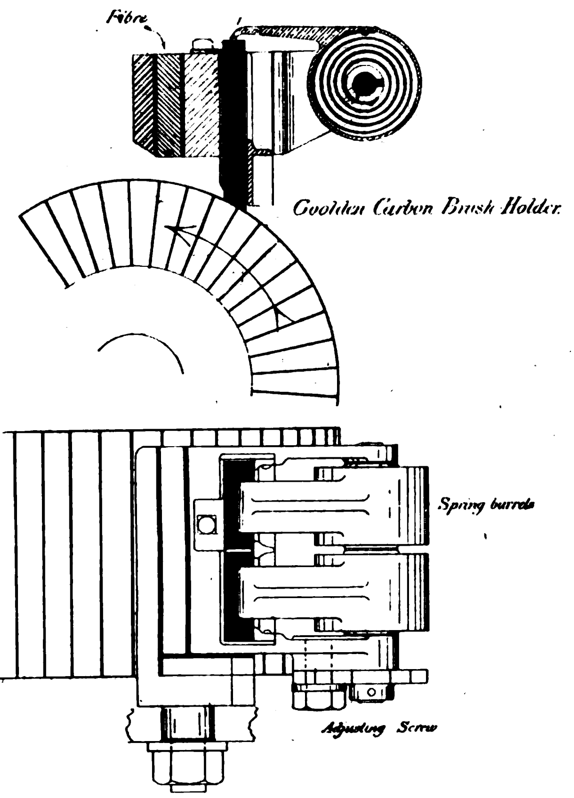

Fig. 5.

the brushes are worn down, the wearing end gradually drops away from its proper position, until (if left without adjustment for a long enough period) it becomes almost square across, and causes sparking by reducing the lead.

Designers of carbon brush-holders appear to have borne this in mind, with the result that in most types the brush remains in the same position relatively to the commutator.

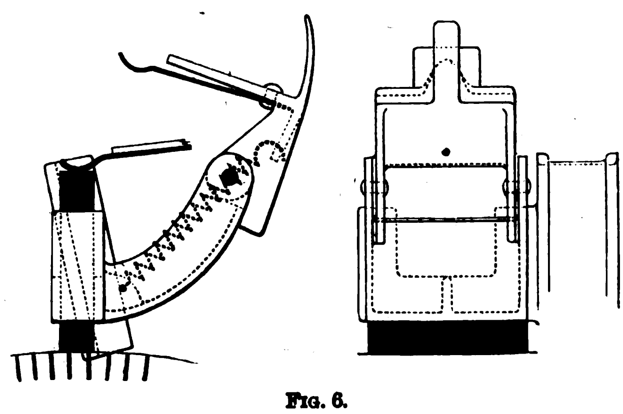

Fig. 6.

It has also, no doubt, been partly due to the fact that carbon wears perfectly with a square end; in fact, reversing motors must of necessity have the carbon in the radial position.

Fig. 5 shows a type of brush-holder which was designed for the earlier Goolden motors for use in colliery work, hauling, coal cutting, &c. It was one of the first to take advantage of the tangential action of the commutator to prevent chattering, a point of considerable importance not only on account of the noise and sparking at the commutator, but also because it is liable to set up sparking between the carbon and its holder.

The barrel with its concentrically coiled spring, shown in sectional elevation in the figure, makes a very neat arrangement, but in the event of the spring breaking or loosing its temper, it is a trifle awkward to replace. The carbon blocks were $2\frac{1}{2}$ inches long × $1\frac{1}{4}$ inches × $\frac{3}{8}$ inch thick, and were covered with a layer of electro-deposited copper.

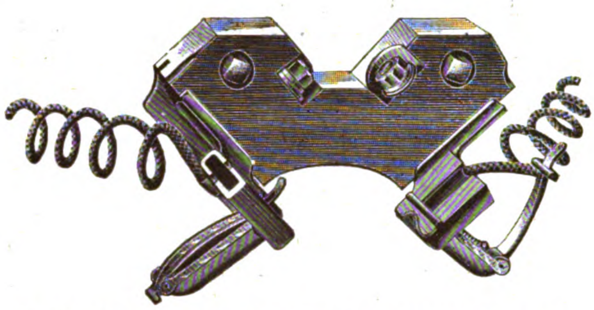

Fig. 7.—Brush-Holder of the Steel Motor Company, Johnstown, U.S.A.

Fig. 6 shows a side and end view of the brush-holder of a Thomson-Houston tramcar motor as made by the General Electric Company of America. The finger or hammer lever is shown in the raised position with the spiral spring just below the centre of the pivot. The end of the finger is also shown dotted resting on the top of the carbon

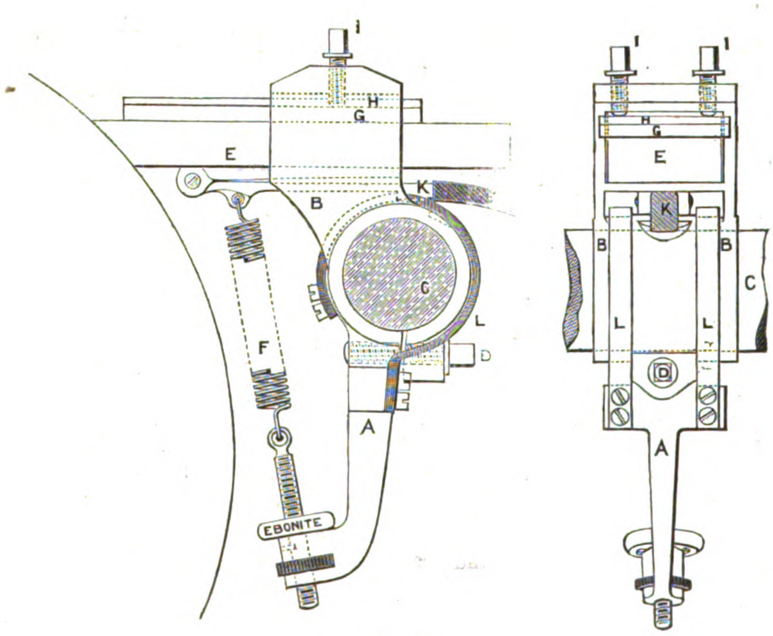

Fig. 10.

block as it would be in actual work. When new, the carbon is $3\frac{1}{2}$ inches long and has a bearing surface on the commutator of $2\frac{1}{2}$ inches by $\frac{1}{2}$ inch. The slot in the brush-holder casting is deep enough to allow the carbon wearing down to $1\frac{1}{2}$ inches long, the pressure due to the spring being about the same during the whole of the travel.

Fig. 7 is taken from a photograph of a pair of carbon brush-holders made by the Steel Motor Company, of Johnstown, U.S.A. The carbons are removed, and the right-hand holder is shown with the hammer lever caught back ready for a carbon to be put into position. The brush-holder yoke is fastened to the top half of the motor frame, and it can be removed along with the brush-holders without disturbing the adjustment, this removal being affected through a malleable iron cover on the top casting of the motor.

The Walker Manufacturing Company, of America, makes the type of holder shown in fig. 8, which allows the carbon block to adjust itself to a bearing, whilst at the same time advantage is taken of the rotation of the commutator to keep the carbon firmly pressed against the metal part of the holder. The current does not therefore have to pass through bearing surfaces or springs, and the type is on this account very suitable for large currents. The facility with which the old carbons can be removed and a new set put in, is a very noticeable feature, and it will also be noticed that chattering is entirely prevented.

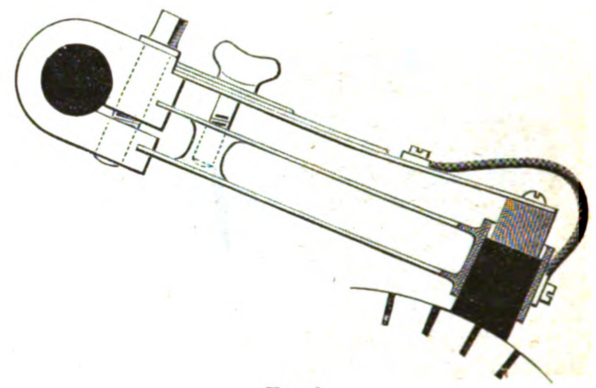

Fig. 9.

Spiral or coiled springs are always more or less a nuisance, and attempts have therefore been made from time to time to use flat laminated springs for the purpose. Fig. 9 shows a brush-holder with a spring of this type similar to those used on the motor-generators at the Electric

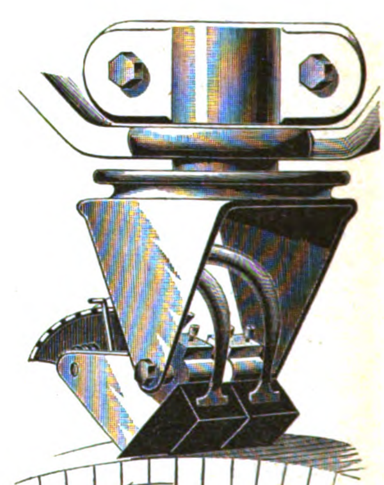

Fig. 8.

Cab Company's charging station, Lambeth. The design is somewhat crude, but judging by the appearance of the commutator it seems to answer its purpose very well.

Fig. 10 shows a well designed brush-holder made by Siemens Bros. & Co., of Charlton, and fitted by them to the large dynamos for the new Waterloo and City Railway. The carbon block is 7 inches long, 2 inches wide, and 1 inch thick, and in order to make it bed more easily it is held in place by an ordinary copper gauze brush as shown in the figure. The action of the holder is as follows:—Casting B moves round the fixed spindle, C, whilst the casting, A, may be firmly clamped to C in any required position by the screw, D. The main part of the current is conveyed from the brush casting, B, to the spindle, through the flexible copper strips, L, and the carbon block, E, can be lifted and held off the commutator by means of the spring catch, K, which is fitted with an insulated end. The brush is drawn back into position when this catch is released by means of the spring, F, which also allows the pressure of the carbon on the commutator to be regulated.

Fig. 11 shows a carbon brush-holder suitable for a small machine. As will be seen it is very simple in construction, and, of course, it could only be used for small currents.

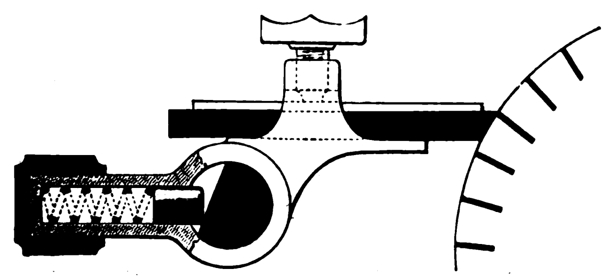

Fig. 11.

The following tabulated particulars of brush gear, &c., may be found useful to designers and others:—Assuming the amperes per square inch of contact for carbon brushes at about a quarter of that allowed for metal gauze brushes, and taking the usual standard sizes of machines and for brushes, the following particulars will hold good.

Amperes.	Metal gauze brushes.		Carbon brushes.	
	Number.	Size.	Number.	Size.
20	1	7 × 2 × ¼	1	3½ × 2 × ½
45	2	7 × 2 × ¼	2	3½ × 2 × ½
75	2	7 × 2 × ¼	3	3½ × 2 × ½
115	3	7 × 2 × ¼	3	3½ × 2 × ½
165	3	7 × 2 × ¼	4	5 × 2 × ¾
225	4	7 × 2 × ¼	4	5 × 2 × ¾
300	4	7 × 2 × ¼	5	5 × 2 × ¾
450	5	7 × 2 × ¼	5	7 × 2 × 1
600	6	7 × 2 × ¼	6	7 × 2 × 1

The sizes of brush flexibles may be taken as given in the following table, which is based on a current density of about 2,000 amperes per square inch.

Diameter of copper in inches.	Area in square inches.	Maximum safe current in amperes.
⅛	·009	20
3/16	·021	45
¼	·037	75
5/16	·058	115
⅜	·083	165
7/16	·112	225
½	·150	300
Two 7/16	·224	450
Two ½	·3	600
Three ½	·45	900
Four ½	·6	1,200
Five ½	·75	1,500

The widths of commutators vary a good deal, but they are all based more or less of the standard 7 inches × 2 inches × ¼ inch brush, as follows:—

Number of brushes side by side.	Width of commutator in inches.	Diameter of rocker spindle.
Two 1" or one 2"	2⅝	⅝"
Three 1½" or two 2"	5¼	¾"
Four 1½" or three 2"	7⅛	⅞"
Four 2"	9⅝	⅞"
Five 2"	12	1"
Six 2"	14½	1"
Seven 2"	16⅛	1¼"
Eight 2"	18½	1¼"

THE UTILISATION OF BLAST FURNACE GASES FOR ELECTRICAL POWER TRANSMISSION.

By W. H. BOOTH.

(Concluded from page 532.)

From a careful consideration of results obtained, it would appear that the amount of power that may regularly and continuously be obtained from a blast furnace is 10 horsepower per ton of coal per week. Thus a furnace burning 1,000 tons per week would yield 10,000 horse-power continuously under correct conditions of work, including the driving of the blast by gas power and sundry other economies into which it is not necessary more fully to enter. The foregoing figures will probably be sufficient to show that there is a calculable saving of enormous extent to be made. My tests of the actual plant more than confirm the figures, and it is beyond cavil that the system is a success, commercially as well as mechanically. Several other plants of utilisation are either at work or projected, including one at the Frodingham Ironworks, one at Barrow, and an entirely new plant, including a new furnace in France; but of more than special interest is one to be put up at the Wigan Iron Company's works in Lancashire, the special interest attaching to this being that a length of 1½ miles of canal has been selected on which to make a trial of electrical traction as

Table I.

	Blast furnace gas.		A gas producer.
	Wishaw.	Frodingham.	
Carbonic acid	5·75	6·0	6·6
Carbonic oxide	24·75	27·3	19·6
Hydrogen	2·33	1·5	6·4
Marsh gas	0·75	...	1·3
Nitrogen	66·42	65·2	66·1
	100·0	100·0	100·0
Heat units per cubic foot ...	97·8	96·7	98·0
Calculated cubic feet per I.H.P.	79·44	80·34	79·27
Percentage combustible ...	27·83	28·8	27·3

applied to canal barges. In this installation a gas engine of about 30 H.P. will be employed, generating electricity for three separate purposes. One of these is the lighting of the ironworks as is being done at Wishaw; the second is the purification of the blast furnace gas itself by electrification, the gas passing through a highly charged field, and depositing its load of dust which aggregates and coalesces and drops by gravity out of the gas stream. The third use of the current is, as stated, for canal barge traction by means of small motors running upon a lattice-framed rail carried on posts along the towing path. There is, perhaps, nothing in the mere transmission of electricity along a short length of canal, but the matter has nevertheless considerable interest as being the first use of electric current generated by furnace gases for power purposes outside the premises on which the waste gas is manufactured. Electrical transmission of power is common, and the problem of the wasteful blast furnace only waits the application of this solution to be at once recognised as a source of power of almost unlimited extent.

If about 10 million tons of fuel are used annually in English and Scotch blast furnaces, then about 2 million horse-power is running to waste. Unlike huge water powers, or even small ones, the utilisation of blast furnace gas does not involve a great capital expenditure on works of preparation such as dams, tunnels, pipe lines, aqueducts, &c., as required where a water power is sought to be developed. Seeing that this 2 million horse-power is located at about a score of centres all over the land, there is an average of

D

about a hundred thousand horse-power to distribute from each. Electrical transmission alone is possible in this matter. It would be sheer waste of time to consider any other system of transmission than that afforded by electricity. The only cost is that of gas engines and cheap light holders, scrubbers, and pipes. To what use can all this current be applied?

The whole of the cotton mills in the country would not, if properly driven, absorb a fourth of the supply. The most obvious use, apart from factories, is that of transportation and light. Between them none of the gas produced in the country need go to waste. Electrical traction may be looked on as the next coming industry, the application to which of the new power involves no rejection of old plant, no change in existing conditions, and no subversion of established ideas. The obvious power for most new tramways is electricity, and it is bound also to be applied to most old lines, if these are to live in competition with new ones.

The application of electricity to main line service may well wait until the tramway system of the country has been modernised and extended. No engineer who had the means at his command need hesitate to undertake the supply of ample power to the London underground railway from the demand exceeds the rate of supply, the addition of a holder will tide over the peak of the demand "curve." Further growth in demand can be met by further storage. The question of storage will not be of immediate urgency. So much power is going to waste that it will be a long time before unbelief is overcome sufficiently to absorb all the power available. In no industry, however, has the production of a large and apparently useless waste been allowed to proceed indefinitely. In the production of the ordinary illuminating gas, the bye-products, once so difficult to dispose of, have become almost the primary profits, and gas has become, in a sense, the bye-product. In the Scotch blast furnaces using raw coal the tar and ammonia recovery has added a very welcome margin to the profits of pig-iron production; and so in many other industries. Yet in none is there so huge a waste as that represented by the gases, still practically thrown away, of the blast furnace, and only capable of employment to their full capacity by the combined agency of the internal combustion engine and the dynamo, with its attendant long-distance transmission.

The recent articles of Mr. J. S. Jeans dealing with the subject of supremacy in iron manufacture have a very close and special relation to this question of waste utilisation.

TABLE II.

Gas.	Per cent. Volumes.	Weight per cubic foot.	Weight per 100 cubic feet of mixed gas.	Ratio of constituents.	Actual weights of elements per 100 cubic feet of gas.			
					C.	O.	H.	N.

iron furnaces of Northamptonshire. Some of the furnaces are at rest. With a very moderate payment for the gas now sent to waste, the profitable joint production of iron and gas would keep these furnaces alight. To Wellingboro' is only 63 miles from London, and the Wellingboro' furnaces are probably the nearest to London. A transmission of 60 miles is nothing to be afraid of. Greater distances are now finished or in hand in America on water-power transmissions. Hence it is perfectly possible and practicable to transmit power to London from Wellingboro' for railroad purposes, adding at one stroke to the prosperity of the decaying iron industry, and rendering the sulphurous underground tolerable. The question of electric traction seems to turn so much on the constant expense of fuel that where this can be had for a fraction of its normal cost there would be great inducement to undertake the building of the transmission line.

It must not be overlooked that the production of blast furnace gas is continuous; furnaces do not stop, but work on for years under blast. The volume of gas produced is enormous, and from one furnace may be a million feet per hour. It is thus essential that, in order to avoid blowing gas to waste, there must either be an immense storage system or the use of the gas must be as uniform and continuous as it is possible to make it. For power purposes of manufacturing establishments there is a fairly constant load over 12 hours of the day, and there is the night load for lighting purposes, but there is rarely much of a load for any purpose beyond street lighting between 12 p.m. and 6 a.m. Assuming that a given furnace is capable of yielding a continuous 6,000 H.P., the possession of sufficient storage capacity to absorb the production of the six night hours would increase the power capacity during the 18 hours to 8,000 H.P., and similarly very much more than 8,000 H.P. would be possible at the hours of maximum demand, such as from 9 a.m. to noon, or the evening overlap of large power and light demand which occurs between 4 and 6 p.m. in winter, where a system of storage is adopted. The storage resolves itself into a question of demand. As soon as the maximum rate of By its means the production of iron in a small country of short distances is placed in a better competitive position than is the case with the furnaces of a large country more sparsely populated and less able to absorb the power production of a furnace within a reasonable radius. This consideration is of great importance to the British iron trade, and, indeed, to the country at large, which is placed in the same advantageous position that is now occupied by countries of large water powers—Switzerland, Scandinavia, or America. Given also increased powers of electrical transmission, and the injustice to Ireland which she has suffered in the denudation of her carboniferous strata may be considerably ameliorated in the not far distant future. These are, however, mere speculations; the solid fact remains that a new power source, of at present unlimited extent, is ready to our hands, and comparatively small expense is needed to utilise it for every purpose of light, power, and even of warmth.

It has been argued that the waste gas might be utilised for similar power purposes by burning them under steam boilers, as now done for the purpose of raising steam for the blowing engines. This argument overlooks the fact that the heating power of all these producer gases and their congeners is very poor. One pound of carbon produces about 7 lbs. of gases, and the minimum air supply is another 6 lbs., so that at the very least a pound of carbon results in the production of 13 lbs. of products of combustion. The carbon has only a calorific value of, say, 10,000 units, one-thirteenth of which, or 770 units, is apportioned to each pound of the products which have a specific heat of about 0·23, so that the maximum possible temperature attainable beyond the initial is only 3,350°, and this is liable, indeed certain, to be very much reduced by the excess of air always present. The flame of carbonic oxide is not a suitable flame for boiler heating purposes, being too transparent, and therefore devoid of radiating capacity. On the other hand these poor gases are very suitable for gas power purposes, and lend themselves readily to the peculiarities of the gas engine, especially in respect of that still unavoidable water-jacket. Rich gases must be diluted, and the poor gas is already dilute and only requires that a slight variation be made in the ordinary proportions of the air and gas inlets and in the piston base for purposes of greater compression. There is no difficulty in igniting these poor gases, in the cylinder of a gas engine, under compression. Gases almost too dilute to burn in the open will readily ignite when compressed.

THE EFFECTS OF ALTERNATING CURRENTS ON THE HUMAN BODY.

By Dr. W. S. HEDLEY.

THERE have lately been recorded (*Electrotechnische Zeitschrift*) a series of experiments undertaken by Prof. Weber, of Zurich, to determine the effects upon the living body of alternating currents at different voltages. Two metallic conductors at opposite potentials were held, one in each hand. With the hands damp, an effective electromotive force of 30 volts, and 50 alternations a second, the whole arm seemed paralysed; extended, it could not be flexed; flexed, it could not be extended. At the same time, the pain was so severe, that it could not be borne for more than five or six seconds. It was not without effort that the hands could be detached from the electrodes. When the voltage was raised to 50, fixation occurred; that is to say, the hands could not by any voluntary effort be released from the electrodes, and the pain was not supportable for more than two or three seconds. With the voltage raised to 80, even with the hands dry, all the above phenomena were accentuated.

Other experiments followed to observe the effect of a current passing to earth through the body; thus, standing on a damp macadamised road, but with dry shoes, a person touching with his hand a conductor at a potential of 1,000 volts experienced a marked burning sensation, and when the conductor was grasped with the whole hand a violent tremor occurred, with complete fixation.

In the same journal M. Emile Kolben gives a case of an accidental contact of several minutes' duration, where the body was placed in the path of a current passing from hand to hand at 200 volts. In our present ignorance of the exact conditions which make electric currents dangerous, experiments of this kind are of great interest and value, and it is desirable that all such cases be assiduously recorded. But it is altogether premature to conclude, because the voltage of electric lighting currents may but little exceed that used in some of these experiments, that therefore such lighting currents are free from danger, or that a person with dry shoes, standing to earth on moist ground, need never be afraid of an alternating current whose potential does not exceed 1,000 volts. In a recent number of the ELECTRICAL REVIEW, reference is made to four fatal cases of accidental contact with live wires, in three of which the potential could not have exceeded 115 volts. Data must for a long time be accumulated, and a great deal more learnt about the human body as an electrical conductor before the line can be drawn beyond which electrical currents begin to be dangerous to life.

BALANCING OF ENGINES.

THE recent paper by Mr. Whitcher, read before the Manchester Association of Engineers, deals with engine balancing on the lines, lately come into fashion, of the bob-weight, a method so obviously correct in theory as to need no demonstration, and, indeed, a method which has been often attempted approximately. As the author points out, the balancing of an engine is an endeavour to hold fast its centre of gravity. Slow moving engines having small energy of motion in any part are sufficiently balanced if they will remain at rest in any position in which they are placed. Such are the old beam engines which can be balanced by a weight in a fly-wheel. In such engines we can neglect the twisting moments about a vertical axis, due to revolution of balanced parts, and their balances in different planes. More quickly moving engines can be balanced by tail cranks and fly-wheel weights, the weight being in the same angle as the crank and the tail opposite, a method very efficient for long stroke engines up to 900 feet piston speed. But these methods do not really balance the piston and other parts which move in right lines; they introduce a vertical disturbing force in horizontal engines, or a lateral force in vertical engines, which have to be dealt with by the absorbing power of more or less heavy foundations.

The conviction of most engineers that a steam engine with two cranks must have these cranks at right angles, has prevented a good deal of excellent work being done. With a three-cylinder engine very good balancing can be effected by keeping the middle crank opposite the two outer cranks and of equal weight to the sum of the two.

Mr. Whitcher considers one of the most important effects of balance to be the effect on bearing surfaces, and he shows how alternating stresses on bearings which produce knock may be converted into rotary stresses free from knock. A revolving counterweight does this at the cost of introducing a general vertical want of balance. He describes briefly various methods, and regrets that the three-cylinder engine with cylinders at 120° on one crank is so inconvenient a machine, being perfectly balanced by a single weight opposite the crank. He criticises the six-cylinder Willans idea, considering the four-cylinder idea of Messrs. Schlick, Yarrow and Tweedy to be superior and simpler where the cranks are placed nearly 90° apart, but so far different from 90° as to correct the irregularity due to angularity of rods. He recommends his hearers to attack the problem from this point.

For two-crank engines, nothing, of course, can be better than a crank angle of 180°, with cylinders as near as possible to each other to suppress twisting moments. With three cylinders there is a fair balance possible. Four cylinders are better. For single engines there is the bob-weight system, and the author questions if it be not better always to treat every cylinder alone, and give up the attempt to balance moments by means of multi-cylinder schemes.

One of the author's methods is to lengthen the connecting rod beyond the crank-pin, and put a bob end to it, so as to balance the transverse component introduced by the rotary crank tail. The same effect is shown by a system of linkage which will obviate stresses otherwise brought on the cross-head slides by the previous system.

Mr. Whitcher makes a severe dig at locomotive engineers who of all men, with unbalanced vertical components in a heavy machine, set to run over rails supported at intervals only, and over costly bridges easily damaged by vibration and its cumulative effects, ought to seriously consider balance. He suggests how locomotives ought to be balanced. The present writer would balance locomotives by giving them three or four cylinders with the cranks of the outer cylinders 180° from the inside crank or cranks, and with equal mass moments. But locomotive engineers apparently dare not depart from their antiquated ideas of cranks at 90° so as to be able to start from any position.

They will not accept the little turning engine, so easy to be applied, nor will they try the above system with the cranks slightly off the 180° position, which would generally secure a start, and yet would so greatly reduce the present vertical component so destructive of rail joints, bridge floors, and girders.

Mr. Whitcher's paper is deserving of study and attention, because balancing, though really a simple matter, is by no means always so simple in practice as in theory. Its difficulties arise with frequent reciprocation of parts, and disappear altogether in electric motor work and steam turbines.

ELECTRICAL ALLOYS.

By ROLLO APPLEYARD.

(*Concluded from page* 537.)

II.—NEW ALLOYS.

It was thought that some further diminution in temperature coefficients could be obtained, for it was found that with some specimens of patent nickel examined at the

Reichsanstalt this constant had fallen to 0·00017. It appeared that this diminution resulted from increase of nickel in the constitution of the alloy. A number of experiments were therefore made with copper and nickel, or similar metals, in order to investigate the effect of the quantity of nickel upon the temperature coefficients. Alloys of copper and manganese, such as were being made by Dillenburg at the Isabell foundry for parts of machinery, were examined. The Reichsanstalt were encouraged to pursue this investigation by the success of the patent alloys of Weston, of Newark (American patents Nos. 381,304 and 381,305), which were described as having negative temperature coefficients. Twelve nickel-copper alloys, with different quantities

of nickel, were therefore specially manufactured for them by Basse and Selve, in Altena, Westphalia. The specific resistances and temperature coefficients were determined from wires of 0·5 mm. diameter and about 2 m. long, soldered to copper contact pieces, and, after their diameter and length had been measured, wound double upon a strip of mica, as represented in fig. 1. Afterwards these wires were kept in a thermostat at 120° C. in a dry heat for 24 hours. The wire was then put into an oil bath, and its resistance was measured at different temperatures. The results corresponding to both groups of alloys are given in curves in figs. 2 and 3. Abscissæ in fig. 2 represent different alloys of nickel, the ordinates marked ρ represent the specific resistance in micro-ohms per cc.; those marked α represent the temperature coefficients, giving the significant figures after four decimal places. The ordinates drawn to meet the curves represent the observed values. Fig. 3 sets forth the same data for manganese alloys. Fig. 4 shows the variation of resistance with temperature for various alloys of manganese and copper. These alloys can only be examined up to 30 per cent. of manganese, as alloys beyond that limit cannot be worked.

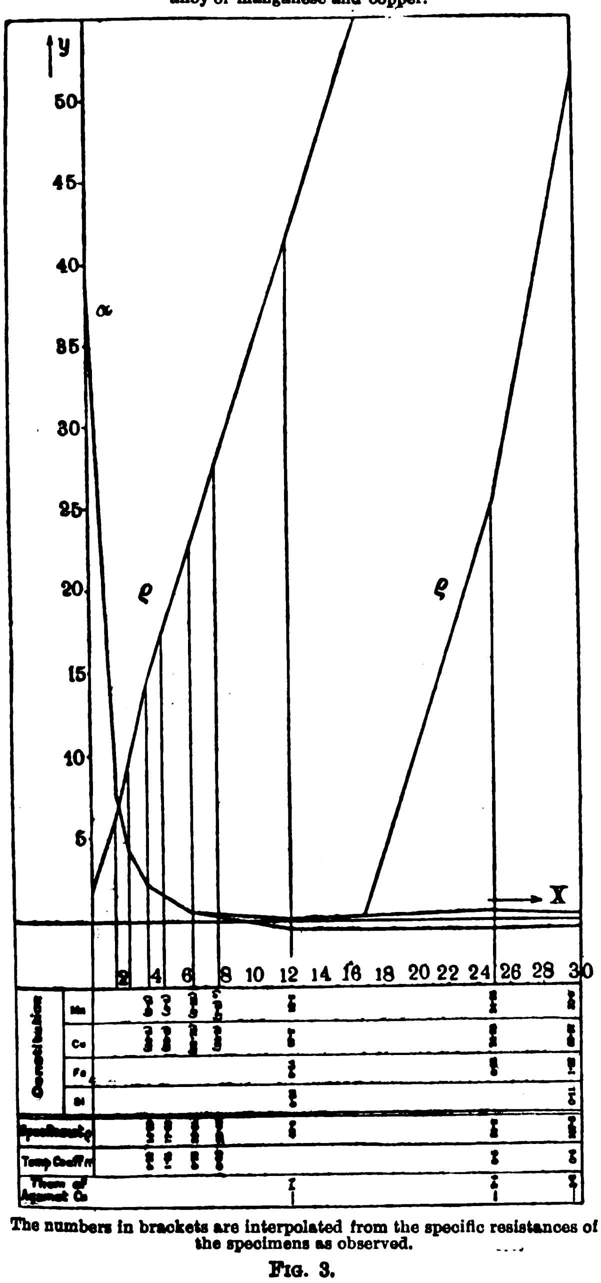
Both with copper-manganese and copper-nickel alloys, the specific resistance increases in proportion to the added manganese or nickel; up to this 30 per cent. value, the resistance of copper-manganese increases about 2·5 times as rapidly as copper-nickel. With the latter alloy, the resistance then diminishes up to 46 per cent. of nickel, and then remains fairly constant up to 62 per cent.; after that, it falls steadily until the metal is all nickel.

With manganese-copper, the temperature coefficient diminishes at first very rapidly, then gradually slower, until at 7 per cent. of manganese it becomes *nil*. Beyond that point, increasing the quantity of manganese produces an alloy which at 0° C. has a small positive temperature coefficient; this vanishes at from 40° C. to 50° C., and beyond that temperature assumes increasing negative values. In fig. 4 the ordinates of the seven curves show these various results, each represents the change in resistance experienced by a wire of 1 ohm when its temperature is varied from 0° C. to 100° C.

With nickel-copper the diminution of temperature coefficients as the nickel is added, is slower than the change noticed when manganese is added to manganese-copper; it is slower in the same proportion as the increase of specific resistance is less. Close to the zero-line there is a bend to the curve of alteration of temperature coefficients, the second part of the curve is not horizontal, but has a slight upward inclination, and then falls somewhat rapidly towards the zero line at 46 per cent. of nickel. This alloy gives the least temperature coefficient. At this same 46 per cent. value the specific resistance also attains its maximum.

The alloy represented by F (fig. 2) has approximately the chemical formula Ni Cu. In these alloys it may be supposed that the combination of one molecule of nickel with one of copper is mixed with different quantities of copper and nickel, and that these possess high specific resistances and negative temperature coefficients. The practical result of this investigation is to show that it is possible to obtain two kinds of alloys with vanishing temperature coefficients. With manganese-copper only 7 per cent. of manganese is required to produce an alloy of infinitesimal temperature coefficient. In practice, 12 parts by weight of manganese, 2 of nickel, and

Temperature coefficient α, specific resistance ρ the constitution of the alloy of manganese and copper.



The numbers in brackets are interpolated from the specific resistances of the specimens as observed.

Fig. 3.

86 of copper are adopted. Nickel has the effect of raising the thermo-electric force against copper, besides delaying the bend of the curve of resistance variation with temperature by about 20° C. (see fig. 4). This alloy has received the name of manganin. It is specially made at the Isabell Foundry for standard resistance coils. Fig. 5 shows the change in resistance of a 1-ohm coil of manganin at various temperatures; the observation-points on the curve are numbered for purposes of reference.

From the curve given in fig. 3 it appears that there are only two alloys of nickel and copper for which the temperature coefficient vanishes. The relative merits of these two alloys remain to be studied. Messrs. Basse & Selve, of Altena, who have made all the sample alloys for the Reichsanstalt throughout this investigation, make an alloy with 40 per cent. of nickel, corresponding to the first coincidence of the curve with the abscissæ axis, and they have given this alloy the trade name of "constantan."

Important as is the production of an alloy possessed of a vanishing temperature coefficient, such an alloy cannot be adopted for standard coils until the permanence of the specific resistance has been firmly established. Experiment seems to have proved that manganin and constantan are, in this regard, as suitable as patent nickel. In considering other properties, the thermo-electric power against copper comes first under notice. The table given below fig. 3 shows that manganese-copper has only small negative values for this power; this can be got rid of altogether by adding a trace of nickel to the alloy. On the other hand, nickel-copper, and especially constantan, have high thermo-electric power against copper; these are given in micro-volts in fig. 2, for different proportions of nickel.

The recorded values were determined by soldering the ends of the specimen wires to copper wires that were connected to a galvanometer. All the wires were contained in an oil bath kept at constant temperature by a heating spiral and a stirring wheel. The thermo-electric power disturbed the resistance measurements, especially when low resistances and strong currents were employed. It is true that these defects can generally be eliminated by care in the construction of the apparatus, but for resistance measurements of great precision, it is almost essential to have a material such as manganin, for which the thermo-electric power against copper is *nil*.

Manganin is rather easily oxidised; this, no doubt, is due to the affinity between the manganese and the oxygen of the air. At 100° C. the wire soon tarnishes, and during annealing, the surface manganese is perceptibly oxidised out of the alloy, leaving a surface of copper beneath the oxide. As might be expected, the electrical qualities suffer in consequence. The surface of copper can be removed by "dipping" in nitric acid, after which the good qualities of the manganin are restored.

Surrounding the manganin with powdered charcoal during heating does not sufficiently preserve it against oxidation. Moreover, dipping in acid is impracticable with the finer wires. At first this question of rapid oxidation at annealing temperatures presented a great difficulty to manufacturers of manganin wire, but the wire drawers have now learnt how to draw manganin cold, even to very fine gauges, so that the trouble is very much lessened. By varnishing the finished coils with shellac, it is found that the wire is rendered proof against oxidation, at any rate up to 150° C.

Constantan, on the other hand, resists oxidation. It can be heated with impunity up to 300° C. On account of its strength and flexibility it can be drawn into fine wires or rolled into strips. For many electrical purposes—for instance, where considerable heating is to be expected—the qualities of constantan are of great value; but for standards of resistance manganin takes preference, chiefly because of its small thermo-electric power against copper. In jointing manganin wires to the copper connecting pieces for standard resistances, tinman's solder was previously used, applied with a soldering iron. But this method is found to be detrimental; it produces in the course of time very perceptible changes in the resistance. The soft solder causes fissures, and generally alters the structure and properties of the manganin. The present method employed is to solder the wires with silver solder to copper lugs that are screwed under the contact pieces, so that they can be removed if necessary. All coils, after varnishing several times with shellac, are dried for some hours at 140° C. In winding, the insulated wire is not touched by the hand, but is passed through a clean dry cloth. The bobbins are made of as large diameter as possible, and other precautions are taken to avoid bending of the wire. It is often found better to use several thinner wires in parallel than a single thick one.

CENTRAL STATION PLANT ON BOARD SHIP.

In connection with the, of late, frequent reference to the extravagances of auxiliary plant, we note the remarks of Mr. W. S. Aldrich in a recent paper read to the American Society of Naval Engineers. On board ship the distances are so small that line losses are negligible. They are not, however, negligible in the case of steam. Compressed air is perhaps the best means of storing energy on board ship. Hydraulic accumulators as well as secondary batteries are dismissed as quite unsuitable. Electricity alone seems altogether suitable to economically transmit power from a central point where engines of economical type can be installed near to the source of steam. The power plant should consist of a number of similar self-contained units. The range of power will be less on any one unit than on the several steam engines used to drive scattered auxiliaries. On board ship there can also be arranged very steady loads, and the plant may run day and night at nearly uniform load, the light by night being set off during the day by additional motor loads, while certain pumping machinery can be operated at any time to compensate for unavoidable load variations. The one in charge of such a plant could, in fact, so work it as to secure a load curve the envy of a shore station manager. Quoting from *Transactions American Institution Electrical Engineers*, Vol. xiv., it is shown from Mr. Foster's paper that plants above 200 H.P. show a remarkable uniformity in the fixed charges of interest, depreciation, taxes, and insurance. Operating expenses gradually decrease in plants from 200 to 1,000 H.P., above which they remain very uniform and irrespective of load variations. Large stations supplying many smaller industries are scarcely affected by the instantaneous load changes. On board ship the mains can be safely and securely run through watertight bulkheads, and generally the system is, like the cables, most flexible. Only distribution losses on branch circuits need to be considered in detail. Main line losses are too small for consideration. Direct current in all cases is to be used. Distant motors can be controlled with known certainty from the central point. The author states that there is not a single auxiliary which cannot be electrically operated with certainty, efficiency, and economy, and he enumerates all fans, pumps, blowers, hoists, shifting and steering gear, turret gear, and gun mounts as daily reaching towards the system of electrical operation, also the air compressors for refrigeration purposes.

JOINT TEST: AN ACCUMULATION NULL METHOD.

By E. RAYMOND-BARKER.

In all joint tests hitherto employed two operations are necessary. Whether in Clark's *accumulation*, the *discharge*, or the *electrometer* methods, the main feature of the test lies in the comparison of two deflections.

These deflections are proportional to the amount of current which, in a given time, has leaked into or out of a condenser or into an electrometer, through the respective dielectrics of joint and standard core.

In practice, indeed, frequently three operations are gone through, viz., testing loss on (1) trough; (2) trough and joint; (3) trough and standard core.

It is quite possible, especially in work at sea, for atmospheric conditions accompanying the two main operations of a joint test to be not perfectly constant. Brine laden squalls, intermittent with sunshine, will cause variation of leakage, which scouring of ebonite would seem, at times, powerless to wholly get rid of.

For these reasons a test in which both joint and standard core are tested simultaneously, would appear to have points in its favour. It was under the influence of this idea that—some two years ago—the writer devised the subjoined test.

The accompanying diagram shows the connections of this test which is practically an *accumulation null method.* T is a double trough of ebonite. The usual precautions are taken as regards good insulation, and to prevent leakage between the two trough compartments.

The core with the joint, and an equal length of similar and perfect core, are laid in their respective compartments and are immersed in salt water. The joint will previously have been hardened in ice or freezing mixture.

P_1 and P_2 are copper plates for effecting connection between the water in the respective trough divisions, and the instruments.

C_1 and C_2 are two mica condensers of equal capacity, each, say, one microfarad.

K_1 K_2 is a Price mixing key (shown as a Lambert for ease of illustration).

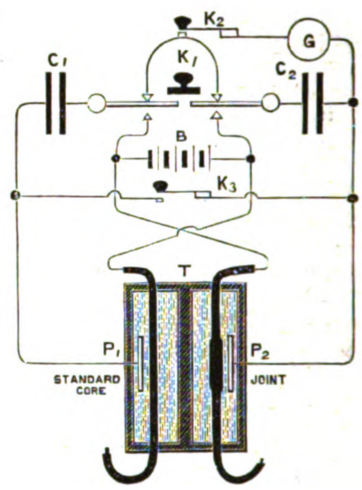
K_3 is an ordinary make-and-break key.

G is a sensitive mirror galvanometer.

B is a battery of high voltage.

For the test, K_1 is depressed during a certain fixed time, say, for one minute. The current leaks through core and joint respectively into C_1 and C_2 in which charges of opposite polarity accumulate.

K_1 is then raised, allowing the accumulated opposite charges in C_1 and C_2 to mix and tend to neutralise. K_2 and K_3 are at once depressed, thus discharging through G any



residue of unneutralised charge. The consequent deflection throw will be to the one side or the other of scale zero, according as joint or standard core has the higher insulation. If the two are equal the deflection will be *nil*.

The side of scale zero indicating that the joint has the higher resistance can be decided once and for all with any given arrangement of instruments, by simple experiment with two lengths of core or leading wire of known inequality of insulation; or, again, by testing for loss on the trough with an artificial leak on one side of the same.

For the joint test proper, when a considerable length of cable may be in circuit with the joint, C_1 and C_2 ought each to be short-circuited until K_1 has been depressed. C_1 and C_2 are then simultaneously unplugged, this operation determining the moment from which the time of charge is to be noted.

By the use of slides or of two high resistances, one being adjustable, this test may be modified so as to afford a perfect *null* method.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Two interesting papers occupied the Institution at its extra meeting on Thursday, April 28th. Mr. H. F. Parshall presented a detailed review of his practical experience of the return circuit in electric traction in his paper, "Earth Returns for Electric Tramways," while the question of return feeders was dealt with by Major Cardew and Mr. A. P. Trotter in a joint paper entitled, "Notes on Electric Tramways."

After the papers had been read, Mr. Gadsby opened the discussion by referring to Mr. Parshall's statement that, where lead-sheathed cables run parallel to earth returns of tramways, the results have been entirely unsatisfactory, since, in the absence of bonding, the lead sheathing is rapidly eaten away. The serious difficulties which arise with such cables makes them unsatisfactory indeed; holes as large as a shilling are sometimes eaten out by the return currents; in tropical climates, where the soil is dry for the greater part of the year, it is found that when rain does fall, and these places are exposed to wet, the cable breaks down. Mr. Gadsby thinks that track welding will be adopted for all tramway work in the next few years; where cast-welded bonding is adopted, good results might be obtained by permitting the metal to overflow or run out at the other side, so as to raise the temperature of the rails sufficiently, but it is a mistake to try and get the weld on so as to have an extremely small amount of clearance. Where rails are laid on white oak sleepers on broken stone, as is the practice in the United States, the conditions are different from what is customary in the country, where a concrete foundation is put in, and there is not much likelihood of trouble with the latter system.

Mr. Gadsby has designed a rail with a separate tread, with the idea of renewing that part of the rail which is subject to wear, and of making the tread of the most durable grade of steel. By stepping and breaking the joints the rail can be made to bond the tread and the tread the rail. With reference to the apparatus and method used in measuring the resistance or joints and rails in position, Mr. Parshall has not stated if or how the resistance of the shunt or parallel path provided by the earth between the test points has been allowed for.

Coming to Major Cardew's paper, Mr. Gadsby considered that it would be impossible to apply the "different voltage" arrangement to a complicated tramway system, but there seem to be some cases in actual practice where the use of feeders of different resistances might be of use.

A certain tramway, not 100 miles from London, exhibits certain interesting features. The tests taken as set forth by Board of Trade Regulations give for the drop in the rails a figure not more than 1 volt, but the leakage to the earth-plate shows 10 per cent. of the total current, the explanation of this being that the generating station is over 300 yards from the line, and an insulated feeder runs from the station or power house to the line terminus. On this feeder there is a drop of from 5 to 6 volts, with the result that the whole of the rail system is some 4 or 5 volts above the earth.

Another speaker referring to the cast-welded joint, thought that it should be bonded electrically, otherwise it does not prove at all a successful system; while Mr. Heaviside described an experiment he had made showing that rails must be insulated completely if it is desired to prevent currents flowing through the earth.

Mr. A. J. Lawson thought that Mr. Gadsby did not recognise the effects of pipes in the subsoil, and the circumstances he had mentioned might be not altogether, but only partially due to the cable in the return, as water and other pipes being connected across and buried in different soils leading up to the generating station would modify the direction of current flow.

A mixed contribution, partly Prof. Ayrton and partly Prof. Perry, followed. Prof. Perry had sent his remarks in writing to Prof. Ayrton for submission in the discussion, and as the speaker and the writer did not always hold the same opinions, the result was somewhat amusing. Prof. Perry thought the most important explanation in the paper by Mr. Parshall was his experience that well-made bonds do not increase in resistance. The exposed surface of the rails is very large, some 50,000 square feet per mile, and the consequences of this should be carefully considered by electrical engineers. Again, in the interests of the companies, Prof. Perry would say that the return should be insulated; whether there should not be a rule, for example, that *all* electrical conductors should be insulated, even though it is known that the Board of Trade rules will partially protect pipes, &c., buried in the ground. New York and Boston have already insisted upon this point—the extra expense need not prove excessive. Prof. Perry ventured to disagree with Prof. Ayrton as to the degrees of importance of educational or teaching institutions being guarded against disturbance from earth currents. Magnetic observatories, however, suffered severely. The value of all records of the Washington Observatory is now destroyed, although two miles away from the source of disturbance, while those of Toronto are useless. At three-quarters of a mile the variations may amount to a half or more of the diurnal variations it is desired to record. While a laboratory may be protected, it is impossible to defend an observatory, and if Kew were interfered with, no money compensation would be commensurate with the damage inflicted. There seems to be no other way in which to obtain a knowledge of the cause of the earth's magnetism than the study of magnetic records.

Then there is the amount of harm that may be done by uninsulated returns to pipes and lines in their neighbourhood. When sewage was cast into rivers the general rights of the community suffered, and steps were taken to prevent future interference. As Prof. Ayrton has before stated, he repeated again, that the use of earth returns was an evidence of conservative feelings of the human being. As earth returns are used for telegraphy, it seems natural to some that we should bring back the current of tramway lines in the same way. There is a talk about zero pressure on the return lines (and of apparatus for effecting this). Who wants them to be at zero? Why should one interfere with the pressures at all? It is an old-fashioned idea that one must do everything by the same means. In ancient days a hole in the roof of a hut let in light and allowed smoke to escape, in later times separate provision was made.

Prof. Ayrton has mentioned on previous occasions that all the railway companies which had Bills in Parliament for the construction of underground railways near South Kensington had undertaken and did insert clauses to the effect than an entirely insulated system would be employed; all had given undertakings that whether a two or three wire were used every bit of the system should be insulated to the satisfaction of the City and Guilds of London Institute and the Science and Arts Department, and had agreed to their right to see that the undertaking was duly carried out. It was to the interest of the companies, who could then construct their lines with best consideration from a purely engineering point of view. Not only would other people not be disturbed, but an enormous benefit would be derived by the companies.

Prof. S. P. Thompson agreed that a standard laboratory should not be interfered with. It was true that Toronto can no longer make magnetic records, but a student's teaching institution is on quite a different footing, and he saw no reason for protecting a laboratory of this kind; rather let the students find out what occurred. He did not apparently favour the plastic bond, and urged the absolute inadvisability of having anything to do with quicksilver. Referring to the thermo-electric effect which interferes with resistance measurements such as Mr. Parshall had taken, he pointed out that the Peltier effects suffered reversal when the testing current was reversed. As Mr. Parshall did not find the tests unaltered by change in direction of current, this was evidence of something else that was not mentioned, as one did not have symmetry. Again with respect to "gathering" the resistance of a conductor is a minimum when the current flows equally through the cross-section, and it is obvious that the useful section diminishes close to a bond, but the professor was utterly astonished to find the "gathering" resistance was represented by 39 inches of good steel rail and hardly thought that "gathering" could be responsible for all that. He thanked Major Cardew for his clear account of how to keep down the drop by return feeders and boosters.

Prof. Thompson was aware that there had been much grumbling at the Electric Lighting Act of 1882, but it is now regarded as a blessing in disguise, as it has saved us from a great deal of abominably bad work: the Board of Trade Traction Rules are a blessing, and not this time in disguise—one need not have quarrelled with them on question of economy had they been more severe than they are.

Mr. Wordingham had come to the conclusion that there was no alternative in some cases to insulating the return. A great objection to slot and conduit systems was the length of time the highways had to be closed for laying—three weeks to a month. Insulated overhead returns had resulted in failure.

Mr. Parshall replied by urging the survival of the fittest.

The four rails of a tramway system represented 6 square inches of copper conductor. The "hole-in-the-roof" argument suited him perfectly; on his basis the hole-in-the-roof became the roof itself! He explained how some of the tests in his paper had been taken, his remarks may be of interest to those who read the paper and reply together in the *Journal*.

Major Cardew briefly replied: He thought that the disturbance at an observatory would depend very largely upon the angle subtended by the tramway at the observatory.

The meeting then adjourned, after a notice by the President that the next paper would be on "The Prevention of Interruptions to Electricity Supply," by Mr. Leonard Andrews.

CORRESPONDENCE.

Carbon Brush-holders.

With reference to the historical note in the first paragraph of Mr. Scott's article on "Carbon Brush-holders" in your issue of the 22nd ult, I may say that although carbon, as Mr. Scott says, does not appear to have been very much used on dynamo commutators until 1892, I remember it being experimented with in the early part of 1889, and largely adopted later by the West End Street Railway Company, of Boston (U.S.A.), on their street railway motors of Bentley-Knight, Sprague & Thomson-Houston constructions.

The use of this material was a decided success, and relieved those in charge of the running of a lot of anxiety owing to the small amount of attention necessary; sparking being practically overcome and wear on the commutator hardly noticeable.

The almost universal adoption of carbon brushes at the present time for street railway work provides ample proof of their superiority on all points over metal brushes, and electric traction engineers have certainly much to thank Prof. Forbes for in suggesting the use of such a satisfactory material.

It is a small detail certainly, but one that has assisted towards making electric traction the success it is.

April 30th, 1898.

"Generation of Electricity at Gas Works."

According to the *Daily Mail*, January 26th, 1898, there are in the United Kingdom 433 private gas companies, 208 municipalised gas undertakings, the majority of which are at the present time making a considerable profit from gas and the by-products or wastes.

During the year 1897 an application for provisional protection for "Generation of Electricity at Gas Works by Utilising the Waste Gases and Heat," was passed by the Patent Office, and the applicant is of opinion that it is possible to generate 30 to 50 units of electricity as well as 9/10,000 feet of coal gas from a ton of coal as well as the usual by-products, coke, &c.

If such is possible, what will be the ultimate cost of electricity?

The capital expenditure of these gas undertakings is stated to be about £66,500,000, and the expenditure on electrical central stations is increasing so fast that the figures can hardly be correctly stated; but it is certain that a large amount expended on land and buildings, if it were possible or practicable to make gas and electricity at the same works, would be saved, besides which there would be considerable saving in the departments of distribution and collecting.

Another feature is the question of Dowson or power gas, made from cheaper coal, having less illuminating but greater motive power; and the combination of some of the systems would obviate the necessity of storing the electricity, which forms the most costly part of an electrical undertaking when "works' cost" is calculated.

The great increase of electrical traction, and the comparative low cost and advantage of electrical motor power and its distribution, and the question of "day load" may be solved by utilising gas works for the production of electrical light and power as well as illuminating and power gas.

All this hinges upon one question: Is it possible or practicable to utilise the present waste gases or heat at gas works for the generation of electricity?

Also, whether the gas companies, which for many years have supplied us with light, heat, and power, are to be superseded?

Now, as many municipalities are owners of the gas undertakings, and have applications for electric light, would it not be worth their while to consider these questions?

Gas engineers have been studying how to improve their light, and electrical engineers how to cheapen theirs, and both have overlooked the fact that it is possible to produce gas and electricity at the same time from the same coal.

What the public want is cheap and good light, heat, power, and quick transit, and the profits thereof to go to the reduction of the rates, and it may be found practicable by combining the production of gas and electricity at one and the same time at gas works.

Bristol.

Free Wiring.

In an article on this subject by Mr. V. Zingler, commencing in your issue of the 22nd ult. and concluding in the current number, it is argued that it is fairer for the consumer, who has the wires and fittings put in for him free of initial cost, to pay in proportion to the actual use he gets out of them rather than for the length of time these goods are in his house. In other words, that it is an all round better arrangement for him to pay a little extra on the cost of the units for the use of the wires and fittings rather than a fixed sum per quarter per lamp put in. I cordially agree with the writer, and feel convinced that the plan which is fortunately being most generally adopted is the one which will work out best in practice, and I hear from the Midlands that a very marked improvement has now been brought forward, which I suppose was not seen when free wiring was first introduced. I refer to the charge for free wiring being made ½d. per unit after the first hour's use at 1d. on the maximum demand basis. This exactly meets the point which Mr. Zingler brings forward, when he says that it may be urged that just as it is found profitable to give the customer a rebate on the cost of electricity after a certain consumption per diem, so it would most likely also be advantageous to all parties concerned to give him a similar rebate on the excess sum per unit for wiring and fittings, the point at which this rebate should come into operation being determined by the sum representing fair interest on capital sunk required from him. Just as when you take a cab for a short trip it costs you 1s., but for a 3-mile run the fare is 1s. 6d., so with the improvement in the free wiring tariff to which I have alluded the customer is not discouraged, by the additional charge for the free wiring, from running his lamps freely and for many hours each day.

Visual Telegraphy.

We have read with mingled feelings of amusement and surprise the numerous and sensational press announcements regarding the alleged invention of Herr Szczepanik.

From interviews with him recorded in *Black and White* and the *Illustrated London News*, we observe that he claims to have originated the idea of employing vibrating mirrors in an apparatus for transmitting views or images of distant objects by electricity.

We may say, however, that as long ago as 1890 we conceived the same idea, and in letters of that date addressed to, and now in the possession of, Dr. Charlton Bastian, F.R.S., we fully described the method whereby this visual telegraphy could be accomplished provided certain mechanical difficulties in the construction of the necessary apparatus were successfully overcome.

Our experience is that the difficulty lies in mechanical construction only, and when Herr Szczepanik has solved this problem he will, indeed, have invented something new.

In the absence of proof to the contrary we must certainly claim to be the originators of the idea of using vibrating mirrors, which, however, is not of much value until some means have been invented for causing them to vibrate at a greater speed than has ever yet been attained mechanically, as in order to reproduce a picture on a screen six inches square with a single electric circuit, the mirror would have to make at least 90,000 (ninety thousand) distinct and intermittent movements in each half second of time, and even at this speed the picture would appear very blurred.

In addition the 90,000 movements of the mirror at the receiving end should be absolutely synchronous with the 90,000 movements at the transmitting end.

We foresee the possibility of reducing the above speed to as little as 300 (three hundred) distinct movements per half second, but then the difficulties of synchronising throughout the longer period of each movement become immensely increased.

It appears evident, therefore, that something more than vibrating mirrors must be thought out before "pictures of battlefields, &c., can be reproduced at a distance with all the clearness of the cinematograph" (*vide Black and White.*)

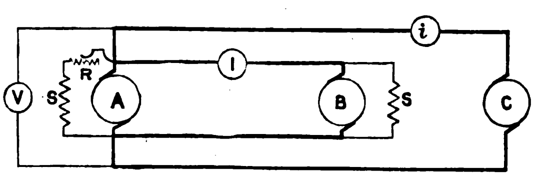
Testing the Efficiency of Direct Current Machines.

On page 548 of your issue of April 22nd appears a reprint from *L'Eclairage Electrique*, by Mons. P. Dupuy, on a method of testing the efficiency of two similar direct current machines. Am I not correct in stating that M. Dupuy is in error in his method of calculating the efficiency? This same test is described briefly by Prof. S. P. Thompson on pp. 759 and 760 of the fifth edition of "Dynamo Electric Machinery," Mr. Kapp being given as its originator.

The formula there given to obtain the efficiency of either machine is:— $\sqrt{\frac{I}{I + i}}$, not $\frac{I - \frac{i}{2}}{I}$ as M. Dupuy has it; where I is the current in the machine running as motor, and i that supplied by the third machine.

M. Dupuy seems to have overlooked the fact that the currents in the two machines are not equal, except when mentioning the Joule effect, where, unless I misunderstand



A, Motor; B, Generator.

him, he makes the currents to be $I + i$ and $I - i$, whereas they should be $I + i$ and I, that in the motor being in excess of that in the generator by the amount supplied by the third machine.

The efficiency obtained is, I take it, that of either machine at an output situated somewhere between the arithmetic mean and the root mean square of $I + i$ and I, being nearer the latter the larger the load. With the figures instanced by M. Dupuy the efficiency should be $\sqrt{\frac{1,000}{1,160}} = \cdot 929$, instead of $\frac{1,000 - 80}{1,000} = \cdot 92$, and the difference between the two methods becomes more marked with a lower efficiency, for instance, with $I = 1,000$ amperes, as before, let $i = 300$ amperes, then the efficiency would be ·877, whereas M. Dupuy would make it ·85.

I have been using this test for some time past in the works with which I am connected, both for obtaining the efficiency and as a handy means of applying a load, and can most fully endorse M. Dupuy's statement as to its convenience. I have found, however, two objections to it, (1) the speed drops below normal; (2) the weakening of the field of the motor is conducive to sparking, especially on toothcored armatures. An easy way of lessening the latter effect is to connect the field coils of the generator (when it possesses more than one) in parallel, and to insert a resistance, cutting this out, and so strengthening its field simultaneously with the weakening of that of the motor; but this unfortunately still further reduces the speed.

M. Dupuy speaks of keeping the external resistance as low as possible, but with machines of large output and low voltage, it is almost impossible to avoid a sensible waste on the leads, switch, and ammeter, which can easily amount to 1 or 2 per cent.

A very approximately correct allowance may be made as follows:—Measure the watts, w, wasted externally, then if V be the voltage of machines, $\frac{w}{V}$ represents that part of i for which this loss is responsible, add half this amount to the generator current and subtract half from the motor current.

$$\text{Efficiency} = \sqrt{\frac{I + \frac{w}{2V}}{I + i - \frac{w}{2V}}}$$

Example:—

Generator current $I = 500$ amperes, $i = 100$ amperes.
Motor current $= I + i = 600$ amperes, $w = 1,600$ watts.

$$V = 80 \text{ volts}, \frac{w}{2V} = 10$$

$\text{Efficiency} = \sqrt{\frac{500 + 10}{600 - 10}} = \cdot 93$, instead of working out to ·913 where these losses not taken into account.

The test is as applicable to compound machines as to simple shunt, but care must be taken that the series turns on the motor as well as those on the generator, are connected cumulatively, otherwise the arrangement lacks stability.

H. B. Poynder.

THE STRATEGIC VALUE OF CABLES.

The present regrettable state of affairs between Spain and the United States, which is a matter of the gravest interest to the whole civilised world, not only on account of the immediate conditions brought day by day before our notice, conditions to which no one can be indifferent, but also on account of the consequences which must inevitably follow when the struggle is concluded, and the time comes for re-adjusting the balance. This situation brings home to us in a practical way a lesson which we should not ignore, although it is not bought by our own actual experience. There are doubtless many points of importance in the war now going on to which the attention of the strategist, naval or military, may be directed with advantage; and there are new problems in politics being evolved which will sooner or later have to be dealt with, but we wish to confine our view to what may seem comparatively a detail of the present complications; yet one which is of the greatest moment, and on which at any time the fortune of war may turn. We have on several occasions laid before our readers our views as to the conditions to which submarine cables are subject in time of war, and have given instances of the invaluable part which these are sometimes called upon to play in such circumstances.

It may, perhaps, be within the recollection of some, that on the occasion of the meeting of the "Convention for the Protection of Submarine Telegraph Cables," which took place in Paris as far back as in April, 1884, a favourable opportunity for establishing the neutrality of cables in war time was unfortunately lost. The result of this convention, at which all the great powers of the world were represented, was a common agreement which, however useful to restrain and penalise wilful damage to cable property in time of peace, did worse than nothing for their protection in time of war.

By formulating and agreeing to Clause XV. of this convention a liberty of action was proffered to belligerents, of which some of them, at least, would have hesitated to avail themselves had not this clause been generally assented to. This portion of the convention reads as follows:—

"*Article XV.*—It is understood that the stipulations of the present convention do not in any way restrict the freedom of action of the belligerents."

It has been said that in case of war cables would be cut when and where necessary, without regard to proprietorship and to after consequences, but whatever moral restraint may have existed before this convention was concluded, or whatever fear of arousing prejudice, if not of provoking actual armed intervention, may previously have existed, has been quite done away with by the *carte blanche* given in the convention. Let us examine the position as it actually stands at present. It is of the utmost importance to each of the combatants that they should have speedy and accurate news of events as they occur, relating to the position and movements of war vessels, the transport and landing of troops, and reports as to the success or failure of the various operations of war. Here Spain is heavily handicapped, as the cable routes by which information may reach the United States are none of them under Spanish control, whereas the cables which united Florida with Cuba, the property of an American Company, are under the control of the United States authorities at Key West. From this point communication with the fleet off Havana, some 90 miles away, can be easily and quickly effected; thus giving the United States a great advantage. The other cable route to the South of Cuba, *via* Bermuda and Jamaica is, we believe, still open, and the line from New York through Hayti to Santiago de Cuba, which belongs to a French company is still working; although it is doubtful if the Spaniards are likely to make use of a cable which lands at New York.

However, we gather from a recent report of proceedings in the Cortes that Spain has taken "the necessary steps to maintain communication." As far as Manilla is concerned there is a single cable from Hong Kong, which until last month was landed at Cape Bolinao and connected with the town of Manilla by a landline some 130 miles long. In consequence, however, of this landline having been cut by the insurgents, the cable was removed from Cape Bolinao and carried direct into Manilla. This cable was interrupted a few days ago, and it is rumoured that the end has been taken on board an American vessel at Manilla for the purpose of establishing direct communication between Admiral Dewey's fleet and the United States; for the truth of this rumour we do not pretend to vouch.

We have on previous occasions given instances of the part played by telegraph cables during various wars, and have shown with what facility these can be destroyed in shallow water. In April of 1882 we published a detailed account of the various occasions on which damage was done to the cables on the west coast of South America during the Peru and Chili war, and the effect thus produced in the course of that war.

We in England have not yet had much practical experience on this subject, it is true that during the bombardment of Alexandria the lines across Egypt, which form the principal link in our means of communication with India, China, and Australasia, were cut by Arabi's troops, but this was little noticed at the time, as telegrams could still be sent to the East across the landlines through Persia, or *via* those which run through Russia and Siberia. Circumstances have changed since that time; we learn that at present the Russians are displaying great activity in Northern Persia, and it is not improbable that in time of need we may find both the Persian and Siberian lines closed against us. Since the time of the bombardment of Alexandria a ring of cables has been put round Africa, which joins the submarine telegraph route to the East at Aden, thus avoiding dangers in Egypt; but these cables are notorious for the frequency with which they break down,* and could not be relied on. Some advantage might be gained by laying a series of cables to Cape Colony, *via* Ascension and St. Helena, and this course has been recommended as one having great strategical advantages. We cannot, however, lend much support to this theory, as this means of communication would be subject to the same danger which threatens all the existing cables to Africa, India, China, and Australasia, it would be liable to be destroyed at the mouth of the Channel in the vicinity of Cherbourg and Brest, where, for more than 150 miles, all these cables lie in water of a depth varying from 40 or 50 to 100 fathoms, a depth at which the cables could be cut with the greatest of ease. We have frequently pointed out the advantages which would be derived by laying a cable from Canada to Australia through the Pacific; a route far removed and naturally secured from the dangers to which the existing cables are subject in many portions of their length. Sir Charles Dilke, who is looked on as an authority in these matters, has said that British cables which followed our trade routes could be patrolled. This sounds convincing, but in time of war it is likely that the Navy will have enough on its hands without telling off a large number of vessels to sail at long intervals along the lines marked down on charts as cable routes. Apart from the lack of foresight evident in this there is an obviously false economy, as the cost of establishing independent and widely separated systems of cables would only be a fraction of that entailed by building a large number of additional cruisers to carry out a patrol duty; which, at the best, would be of little or no use as far as the protection of cables is concerned.

* There are at present interrupted no less than four of the cable sections forming portion of the route to the Cape, *via* the West Coast of Africa; these are the cables connecting Mossamedes and and Cape Town (since April 14th, Benguela-Mossamedes since April 20th, Kotanu-St. Thomé since April 27th, and San Thomé-Loanda since May 4th. Thus, with one exception, all the cables from the Gold Coast to Cape Town are now interrupted. The cable from Sierra Leone to Accra which broke down on April 9th has since been repaired. None of the cables above-mentioned are duplicated.

ELECTRIC TRACTION AT BRISTOL.

Decision of the City Council.

The Bristol City Council, since our last issue, has, at two special meetings, devoted in all no less than six hours to the discussion of its relations with the Bristol Tramway Company with regard to the directors' scheme for extending their system, and working the whole of their lines by electricity. At last matters appear to have so shaped themselves that both the company's Extensions and Electric Power Bills may proceed practically as unopposed measures, except on one point—that with regard to the fares chargeable. It may be that the Sanitary Committee and the company will come to an understanding on this subject in the next few days, but in the light of past experience this is not very likely, and the Parliamentary Committee before whom the Bills come will have, therefore, to decide between the two bodies as to what the fares shall be upon the numerous lines affected. Mr. George Pearson, the chairman of the Bristol Civic Electrical Committee, who was throughout these long debates the spokesman for the sanitary authority, maintained, and other speakers supported his view, that when carefully examined, the Tramway Company's concessions to the city, as a *quid pro quo* for the sanction to use Bristol streets, would be found more apparent than real. The reduction of the fares for general passengers to the rate of three farthings a mile made very little difference in the present arrangements, and on many important sections no difference at all. The company had the prospect, it was argued, of making an immense saving in their working expenses by the use of electric traction throughout their system, and Mr. Pearson contended that the present price of the shares in the company showed what large profits were expected from the use of electricity. With the hopes of these enhanced profits, investors were willing to pay such a price for shares, that the return to them was only £2 13s. 3d. per cent. per annum. As these profits were to be earned by the use of the public roads, it was urged that the Sanitary Committee were perfectly right in their view that there should be a wayleave paid by the company to the city, and a substantial reduction of fares. On the pro-tramway company's side Alderman Inskip was, as before, the chief spokesman, and his main point was that under 11 heads terms had been provisionally arranged between the company and the chairman of the Sanitary Committee, and that these ought to be taken as the bases of settlement rather than to risk by further demands electrical travelling facilities the citizens needed badly. The Council carried his amendment by 32 votes to 30 in the teeth of the recommendations of the Sanitary Committee, and this amendment worded as follows became the substantive resolution:—"That the Bristol Tramways Extension Bill 1898 be allowed to proceed, and the opposition of the Corporation to the Bristol Tramways Electric Power, &c., Bill, 1898, be withdrawn upon condition that the Bristol Tramways and Carriage Company insert in the Bill proper provisions for giving effect to the stipulations Nos. 1 to 11 in the report of the Sanitary Committee, and such other provisions as may be considered necessary for the protection of the public interest, and that the additional stipulations suggested by the last paragraph of the report be not adopted by the Council."

This last paragraph thus thrown aside was:—"Your Committee are of opinion that no arrangement would be satisfactory which does not reserve to the Corporation the right to veto the use of the overhead wire system in certain areas, and provide for the payment by the company of a moderate wayleave for the use of the streets and a greater reduction of fares."—The conditions, 1 to 11, referred to in the resolution, were as follows:—

1. The company are to be allowed to generate electric current and to use the overhead system upon all the existing tramways, and upon the extensions, on condition that if any other system of electric traction, which may appear to the Council to be an improvement on the overhead system, is adopted and worked at a profit of 5 per cent. or upwards on the capital employed, in five or more towns in the United Kingdom, of a population exceeding 100,000 (any district in the County of London under the control of a Vestry, being regarded for the purposes of this condition as a town), the company will adopt that system on notice from the Council, provided that the mileage of the tramways on which the improved system is adopted is approximately the same as the mileage of the company's electric tramways; and provided the Board of Trade decide that, having regard to the length of the company's unexpired period, it is equitable that the company should make the change. Any question as to the approximation of mileage to be settled, in case of difference, by the Board of Trade.

2. The posts and overhead wires are to be subject to the approval of the Corporation, without appeal, as in the Act of 1894.

3. The power of the Corporation over the execution and maintenance of works in the streets is to be the same as in the Act of 1894.

4. The company are not to supply electric current to other companies or persons within the city.

5. The Corporation are to have the right to use the company's posts for supporting public electric lamps.

6. The company are not to be entitled to require the Corporation to supply them with electricity.

7. Of the first additional capital required by the company for the construction of the works authorised by the Bills not less than £200,000, whether issued by means of shares, debentures, or debenture stock, is to be raised in such a way that the rate of interest thereon shall not exceed 4 per cent.

8. Where owners may be required to sell parts only of scheduled properties, the onus of proof that the part can be severed from the remainder without material detriment thereto, shall be on the company.

9. The fares are to be reduced to rates of about three farthings per mile for ordinary passengers, and one-third of a penny per mile for persons (men and women) of the labouring class. The hours for running labouring class tramcars are to be extended so as to include the hours at which women are employed at factories go to work.

10. The time at which the Corporation may first exercise their power of purchase is to be 17 years from May 1st, 1893, and the subsequent periods of seven years, at which the power of purchase recurs, is to be reckoned as from the expiration of the said 17 years. The purchase is to include the whole of the company's undertaking within the city at the time of purchase, whether consisting of tramways or light railways, except the Hanham Light Railway.

11. The construction of the extensions is to be obligatory on the company.

An attempt was then made by several influential members of the Council to add to these 11 conditions to which the company had already agreed, a demand for a wayleave, and it was moved as a further amendment that the company pay to the city 50 per cent. of their net profits after providing for a sinking fund and paying a dividend of 7½ per cent. on their ordinary shares. (The company pay at present partly working by horse-power and partly by electrical power 6 per cent.). This was warmly debated, but was defeated by 34 votes to 30. Then there was a suggestion that children should be charged halfprice as on railways, and this resulted in an insertion in Alderman Inskip's proposal before the words "And subject to such other provisions" of the following clause: "And subject to the scale of fares to be charged being agreed upon between the company and the Sanitary Committee, or failing such agreement to be settled by the Committee of Parliament to whom the Bill shall be referred." This was accepted by Alderman Inskip, and by the Council generally. As the Bills reach the committee stage next week, there was no time for the Sanitary Committee to report the negotiations on fares to the Council, and it was understood the effect would be a contest on the point in the Committee Room of the House of Commons. The company, in a statement, announce that the average distance a passenger is entitled to travel under their proposed fares is 1 mile, 2 furlongs, 5 chains, 76 links for 1d., or ·75d. per mile. By workmen's car the average distance would be 3 miles, 3 chains, 89 links for 1d., or ·32d. per mile. Workmen's cars are, however, run at fixed times only, and are not numerous.

MUNICIPAL ELECTRICAL ASSOCIATION.

A meeting of the Association was held at the Westminster Palace Hotel, London, on Monday, April 25th, at 9.30 a.m., to consider and report upon the clauses having the attention of a joint committee of the two Houses of Parliament. The President, in opening the meeting, expressed regret that the notice sent out had been so short, but the clauses for consideration were so important that it was absolutely necessary the matter should have immediate attention. He then called upon Alderman Higginbottom, of Manchester, who had devoted a very considerable amount of time to the subjects to be considered, and who would be able to give them, he was sure, a very clear explanation of the effect of the clauses. Alderman Higginbottom then carefully explained the clauses to the Association, and explained the course which had been taken by Manchester, Glasgow, Nottingham, Sheffield, and several other Corporations who were represented by counsel before the joint committee. The President then said he would put the clauses one by one to the meeting, and would ask them to consider the same separately.

Clause 1.—"Whether, notwithstanding the provisions of Section 12 (1) of the Electric Lighting Act, 1882, powers should be given in any case for acquiring land compulsorily for generating stations; and, if so, under what conditions as respects liability for nuisance, notices to surrounding owners, and otherwise.

Resolved, that powers for acquiring land compulsorily were desirable, and that such powers should not be coupled with special conditions as respects liability for nuisance excepting as provided for in the Railway Acts.

Clause 2.—Whether compulsory powers of acquiring land for generating stations, if proper to be given in any case, should be given where the proposed site is not within the area of supply.

Resolved, that compulsory powers of acquiring land for generating stations should not be given without the consent of all the local authorities affected.

Clause 3.—Whether, in case of a generating station, however acquired, not being situate within the area of supply, power should be given for the breaking up of streets between the generating station and the boundary of the area of supply.

Resolved, that compulsory powers for opening up streets between the generating station and the boundary of the area of supply should not be given without the consent of all the local authorities affected.

Clause 4.—Whether powers should be given in any case for the supply of electrical energy over an area including districts of numerous local authorities, involving plant of exceptional dimensions and high voltage; and, if such powers may properly be given, whether any and what conditions should be imposed.

(a) With respect to system and plant, and to the construction and location of generating stations, in view of the powers of purchase conferred upon local authorities by Sections 2 and 3 of the Electric Lighting Act, 1888.

(b) With respect to the relations of the promoters to other undertakers, and to local authorities within parts of the area.

Resolved, that no powers should be given for the supply of electrical energy over an area including districts of numerous local authorities without the consent of the local authorities affected, and that no special conditions are required, as the Board of Trade have all powers necessary.

Clause 5.—Under what conditions (if any) ought powers to be conferred upon promoters seeking to supply electrical energy to other undertakers and not directly to consumers.

Resolved, that powers should be conferred upon promoters to supply electrical energy to other undertakers by agreement.

It was further resolved that a witness be appointed to appear before the joint committee to represent the views of this Association as expressed at this meeting, such witness to be selected by the council.

Mr. Gibbings, the president of the Association was appointed by the council to represent the views expressed at the meeting.

LONDON COUNTY COUNCIL.

On Tuesday the Industrial Schools Committee reported that the cost of substituting the electric light for gas at the Feltham School would, according to the advice of the electrical engineer who had been consulted on the subject, necessitate an expenditure of £6,000. The committee did not, therefore, feel justified in recommending such a large outlay, and their suggestion that £800 should be expended on reconstructing the gas works at that school was adopted.

The Bridges Committee mentioned for the information of the Council that they had accepted an offer of Messrs. Laing, Wharton and Down, amounting to £234 14s. 3d., for wiring the brackets and removing the old lamps in connection with the alteration of the position of the lamps in the open approaches to the Blackwall tunnel. The same committee reported the receipt of tenders, a list of which is given in another column, for the lamp columns, &c., required for the electric lighting of Waterloo Bridge.

The Council, on the recommendation of the Building Act Committee, approved plans submitted on behalf of the Charing Cross and Strand Company for an extension of the generating station in Commercial Road, for the erection of a generating station in Penrose Street, Walworth, for the Vestry of Newington, and for an extension of the Bankside station of the City of London Electric Lighting Company.

The Highways Committee reported having received a reply from the Postmaster-General on the subject of the application of the Council, under the Telegraph Act, 1892, for a license to empower the Council to provide a municipal telephone service for London. The reply stated that it would not be competent for the Council, without obtaining the sanction of Parliament, to construct the necessary works and carry on telephone business at the cost of any funds over which the Council has any control. The Postmaster-General further stated that he must await the report of the Select Committee to be appointed by the Government to consider the question of empowering municipalities to undertake telephone exchange business.

The Highways Committee announced for the information of the Council that the Board of Trade had decided to grant the application of the Vestry of Marylebone for an electric lighting provisional order, and that the orders applied for by the County of London Electric Lighting Company and the Marylebone Electric Supply Company for powers in the same parish of Marylebone had been refused.

It will be remembered that towards the end of March, as mentioned in the ELECTRICAL REVIEW at the time, that the Council decided to ask the Board of Trade to insert, in each of the electric lighting provisional orders which might be granted in this or any future session, a clause for the protection of tramways already purchased or likely to be acquired at any future period. In this connection the Highways Committee reported that the Board of Trade had expressed the opinion that full protection was afforded to the Council by the provisions of the Electric Lighting Act, 1882, and the orders made thereunder, by which the Council, as owner of the tramways, would have power, subject to certain conditions, to alter the position of electric lines or works which would interfere with the lawful exercise of any powers vested in the Council, the Board pointed out that Section 15 of the Act provides that where the position of any electric lines or works is altered, compensation shall be made or secured to the owners. In these circumstances the Board regretted that it was unable to insert in provisional orders the clause suggested by the Council.

LEGAL.

WEBLYN v. SHOOLBRED & CO.

THE case of Weblyn v. Shoolbred & Co., was down for hearing in the Queen's Bench Division on Monday, May 2nd, before Mr. Justice Hawkins and a special jury. Mr. Fletcher Moulton, Q.C., Mr. Roger Wallace, and Mr. Gaskill were counsel for plaintiff, and Mr. Lawson Walton, Q.C., M.P., and Mr. Ernest Pollock for the defendants. The action was brought to recover damages for the destruction or partial destruction of a valuable picture, entitled "The Royal Harem," which was on exhibition in the Strand during the latter part of the Jubilee Year.

MR. FLETCHER MOULTON said the damage, which was by fire, was alleged to be due to the negligence of the defendants, in consequence of their having put in an installation of electric light in a defective way.

HIS LORDSHIP (alluding to a vast array of models and electric lighting apparatus in the Court) asked if the case was a patent case. Was all that electrical apparatus to be used before him and the jury? If so he thought it was hardly a fit case to go before a jury.

Mr. LAWSON WALTON said the defendants were anxious that the case should be tried before his Lordship and a jury.

HIS LORDSHIP: I don't know how you purpose to do it; for you may have experiments to make.

MR. FLETCHER MOULTON said there was no doubt it was a technical case, but he thought there would be no difficulty in making either his Lordship or the jury fully acquainted with the facts of the case on which they would have to form conclusions as to what was done in connection with the electrical installation.

Mr. FLETCHER MOULTON said that if his Lordship expressed an opinion that it was not a suitable case to be tried before him and a jury, they would communicate with their respective clients. Both sides were very anxious to have the case tried.

HIS LORDSHIP: I do not think it is a case that could be reasonably tried by a jury or by anybody who has not had some opportunity of making some experiments himself.

Mr. LAWSON WALTON said there were two issues on which a verdict was desired. The first was whether the installation was carefully and correctly done, and the second was whether the fire was caused by the defective installation or had some other origin. He thought that that would involve the calling of considerable electrical evidence.

HIS LORDSHIP suggested that it would be better for experts to make the experiments elsewhere and then give evidence. If there was any likelihood of fire being caused by the experiments he should prefer that they should not be performed in his presence.

After consultation it was agreed that Mr. Fletcher Moulton should take an order referring the matter to an official referee or arbitrator within a fortnight. The parties, with their models and apparatus, and electrical experts, of whom a large number had been subpœnaed, then left the Court.

CROSSLEY BROS. v. JOHNSON.

AT the Greenwich County Court on Friday, before his Honour Judge Addison, Q.C., Messrs. Crossley Bros. sued Mr. W. Claude Johnson, of the Dignaries, Westcombe Park Road, Blackheath, for £21 17s. The sum of £5 was paid into Court by the defendant, who urged that the balance was expenditure caused by the act of the plaintiffs' own servant. From the evidence it appeared that on May 13th, 1897, the plaintiffs sent a workman named Frank Turner to effect certain repairs to the gas engine which worked the dynamo of defendant's private electric light installation. He arrived a few minutes before the dinner hour of the defendant's workman, Suckling. The engine was working at the time, but when Suckling left for dinner he stopped it, and Turner commenced to do his work. Whilst he was removing some bolts from the gas engine it began to work, and Turner noticed sparks on the switch on the wall which turned the electricity from the dynamo either direct to the lights or to an accumulator as might be desired. Turner ran for Suckling, who came and tried to turn the switch, but in consequence of its being partly fused he could not do so, and the engine was finally stopped by Turner who threw off the belt, causing the piston to fall out and the damage, for the repair of which the claim was made, was thus sustained. The plaintiffs' contention was that the switch was faulty, and when put by Suckling, on going to his dinner, at the neutral position, fell to one which allowed the current, in the usual course under such circumstances, to flow back from the accumulator to the dynamo, which thereupon worked the engine, or in the words of his Honour, "the tail wagged the dog." They also contended that Suckling, upon leaving the engine room, should have lifted the brushes of the dynamo, which would have rendered the action impossible. For the defence it was contended that Turner must have handled the switch himself, but his Honour held this to be most unlikely, and found a verdict for the plaintiffs.

KIBBLE v. HARRISON PATENT KNITTING MACHINE COMPANY.

THIS case which came before Mr. Justice Bruce and a common jury at the Manchester Assizes last week, was a claim for breach of contract. Plaintiff was a comedian living in Manchester, and he complained that some electrical work undertaken by defendants for him was executed so badly that he was deprived of a pantomime engagement at the Shakespeare Theatre, Liverpool. The result of this was that he was out of an engagement during a winter season, and incurred heavy expenses in the reconstruction of the work done by defendants. The defence was that the company was not responsible for the way the fittings were made, and that defendants made them perfectly right for the required work. Plaintiff gave defendants an order for the illuminating and wiring of certain dresses, and also for the five batteries required to work them. An engagement was procured with the above theatre subject to the trials of the show being satisfactory. Defendants then informed plaintiff they would not be able to supply a portable battery, but that a stationary one would serve the purpose and the wires would be invisible. When the trials were made the so-called invisible wire, which counsel said was like a piece of clothes line, was used. The trial was a complete failure. The ladies had their wings on all right, and the plaintiff had his battery in the flies with the invisible wire to work it. The first thing they noticed when the thing commenced in the limelight was that the invisible wire stood out even more conspicuously than in the daylight. The next thing they noticed was that lamps on the demon's dress would not light, and plaintiff got his hand burnt. As regards the ladies' dresses some of the lights went out. Although they were angels their lamps were fixed with bitumen, which melted, and the lamps then fell off. As the result of the trial, the manager of the theatre at Liverpool told the plaintiff that "the thing was off," and the engagement was then cancelled. Mr. Harrison, manager of the defendants' electrical department, afterwards apologised to the plaintiff, and said his experiment had been tried and had failed.

Mr. JAMES HILL, a Manchester electrician, spoke of examining four pairs of wings and the demon dress in December last. The lamps in the wings were fastened with some stuff like bitumen, and upon these being lighted the heat generated would have a tendency to soften the bitumen and cause the lamps to fall off. He explained how the defects arose, and said the light was caused to flicker through an intermittent contact. He did not consider the fittings of the demon dress a workmanlike job. He considered it was possible to make a proper installation, and to construct a portable battery for the demon dress without a prior experiment.

Mr. SUTTON, on behalf of the defendants, submitted that the fault did not arise from the work they did. So far as the wings were concerned, the defect was on before it ever came into their hands. As to the demon dress, the defendants simply undertook to supply the things that it required when it was brought to them, but they did not undertake to overhaul it, and be responsible for it.

Mr. H. W. L. HARRISON swore that the plaintiff and he had been in partnership in Peter Street, Manchester, as electricians for stage purposes. Plaintiff worked on the electrical part of the demon dress, and subsequently, when they dissolved partnership, he brought it to him and asked him to put the lamps on it. Plaintiff frequently came to him and went into the workshop and examined the dress while the work upon it was in progress, and expressed his satisfaction with it when it was completed. All the lamps were lighted in Manchester before it left the defendants' hands, but at the trial at Liverpool they would not light. Any displacement of the wires would prevent the lighting.

After further hearing the jury returned a verdict for the plaintiff for £50, and judgment was entered accordingly with costs on the County Court scale.

BUSINESS NOTICES, &c.

Auction Sale.—Messrs. Percy Huddleston & Co. are to sell by auction the contents of the Copper Depositing Works, West Ferry Road, Millwall, E. This is in connection with the General Electric Power and Traction Company (in liquidation) v. Lewis. See our "Official Notices" this week for particulars.

Bankruptcy Proceedings.—An application was made on Wednesday to Mr. Registrar Brougham at the London Bankruptcy Court for an order of discharge on behalf of John Dewhurst, electrician, &c., 52, North End Road, West Kensington. The bankrupt failed last February with provable debts £590, and assets that will realise in all about £200. He attributed his failure to the excessive amount paid to a late partner, to a loss of £130 through embezzlement by a traveller, and to depreciation in the value of the stock-in-trade as estimated for a forced realisation. The Official Receiver reported the following offences, viz., insufficiency of assets to pay 10s. in the £ to the unsecured creditors, imperfect books, and misconduct in not having at once disclosed to the Official Receiver and Trustee the whole of his (bankrupt's) realisable assets. After hearing Mr. White in support of the application, the learned Registrar imposed a suspension of three years.

Electrical Wares Exported.

Birmingham Exhibition.—The Electrical and Trades Exhibition at Bingley Hall closed last Saturday night.

Books Received.—"Steam-Boiler Construction: a practical handbook for engineers, boiler-makers, and steam-users." By Walter S. Hutton. Third edition, carefully revised and enlarged, by the addition of 175 pages and 194 new illustrations. Price 18s. Crosby Lockwood and Son, Stationers' Hall Court, E.C.

"Submarine Telegraphs: their history, construction, and working." By Chas. Bright, F.R.S.E. Published by Messrs. Crosby Lockwood & Son, London. Price £3 3s.

Brown, Boveri & Co.—On April 1st Messrs. Conrad Baumann and Sidney W. Brown were made partners in this well known concern.

Catalogue.—The International Trading Company, of 35, Queen Victoria Street, E.C., who are sole agents in Great Britain and the Colonies for Herr G. Wehr, Sohn, Berlin, have issued a well illustrated catalogue of telephones, microphones, telegraph instruments, electric bells, batteries, and a variety of electrical accessories. The numerous articles are arranged in table form and numbered for easy reference, and the letterpress pages are followed by about 30 pages which are devoted exclusively to illustrations.

Commutator Bars.—Our readers will remember that about six or seven months ago a correspondence took place in our columns in which it was demonstrated that there was room for improvement in lists of stock sizes of commutator bars. We have now received a new list published by Messrs. Thomas Bolton & Sons, for whom it has been prepared by Mr. Theodore Stevens, E.M., A.I.E.E., which ought to prove of considerable utility to designers and makers of dynamos. The list contains over 70 pages of tables which are divided off into three sections: Table I. enabling the dimensions of the bar of any commutator to be easily calculated; Table II. giving a list of sizes arranged according to the number of sections in the commutator; and Table III. giving a list of Bolton's stock sizes arranged according to their dimensions. Messrs. Bolton will send a copy of this useful little book to any electrical engineer who applies at the offices at 90, Cannon Street, London.

Concert.—The Dover Electricity Supply Company held a staff smoking concert on Wednesday last week.

Country House Lighting.—The electric light has recently been installed in Mr. Wood's house at Gwernyfed Park, South Wales. About 180 lights have been fixed, the plant consisting of an oil engine and dynamo with a battery of D.P. accumulators, provision being made for water power or a second oil engine as an auxiliary. The work has been carried out by Messrs. Drake and Gorham.

Dissolution of Partnership.—Messrs. C. Geary and J. Hall, trading as electrical engineers at Swadlincote, under the style or firm of Hall, Geary & Co., and at 164, Corporation Street, Birmingham, as the Birmingham Electrical Accessories Company, have dissolved partnership by mutual consent. Debts will be attended to by Mr. John Hall, and the business carried on under the same name as heretofore.

Foreign Trade.—We have sometimes thought it would be interesting to know to what extent our foreign trade is affected by the official reports of our consuls abroad. The great value of periodical reports of the outlook, accompanied by business hints from official quarters, needs no emphasis in our columns, for we believe many manufacturing and merchant firms who trade with foreign parts, but who, for divers reasons, have not establishments in those countries, have found them of much assistance. During the past few years they have become an essential to the foreign trader, whether from choice or necessity, and with the increasing commercial rivalry between ourselves and other countries they promise to become even more important.

But we have no monopoly in a matter like this, and competitive countries have also their consular trade reports, and we have no doubt that in these any particularly good points noticeable in our business methods are emphasised for the benefit of our competitors, in the same way as we ourselves are kept informed of the efforts of German and other traders with a view to following their example so far as may be practicable.

Electrical manufacturers in this country undoubtedly have plenty to do at the present moment, but a good supply of home orders should not lessen the desire for export business. Everything that can be legitimately done to extend our foreign electrical trade should be taken advantage of.

As a rule we suppose the first thing to be done in the cultivation of a trade with any new district is to watch the opportunity and make a market where none existed before, and having done that, to see that the requirements of that market are catered for in the most thorough manner possible. Were this done, the likelihood of being outdone by foreign rivals would, we venture to believe, be smaller than at present, although the Englishman prides himself upon the fact that his markets are open to all comers, be they friends or foes. That we are not mindful enough of the markets where we should have supremacy is clear, from the remarks of several of our consuls, and we are occasionally thought to give far greater attention to the article ordered than to the man who has ordered it. From one standpoint this is a satisfactory charge, and its outcome is a better quality of goods supplied. The complaint is not that the quality ought not to receive so much attention, but that the customer and the probable customer should be more considered. For instance, it has been attributed to the Englishman that he declines to depart from certain lines and standards of manufacture which he has himself laid down. His manner says, "Take it or leave it; my goods are suitable for home consumption, and they should be good enough for you." But are they? Does it follow that because a thing is suitable for use in England, it can be just as easily applied in the service of the Heathen Chinee? He may be behind the times, but that is not the point, it is a matter of business; and when a man asks for a thing it is the manufacturer's work to supply that specific article if it is at all possible.

What is the result? The German or American trader comes along, and when questioned whether he can supply such and such a thing which his British competitor fails to do, sees a splendid opportunity for ousting his rival, and by hook or by crook he will take and execute the order. The customer does not fail to take a note of all this, and though in the long run he may prefer to deal with the Englishman for other reasons, he for the time being trades with our rivals, and a blow is struck at our supremacy. Mr. Cusack Smith, the British Consul at Samoa, in his report on the trade of the islands during last year, despises the system of circularising which is so largely adopted by our manufacturers, and belauds the personal representation which we have over and over again recommended in these columns. He considers a day's work done by a "civil, ingratiating, well-informed traveller" more than equal to five years' persistent circularising, and quotes a curious instance of German methods in those parts: A German commercial traveller recently visited Samoa with excellent samples at marvellously cheap prices, and obtained £2,000 worth of orders, mainly from British traders, but most or many of his goods were originally made in Manchester. These were ordered by German firms, and marked in Germany with German trade marks, and were sold by the German traveller with the remark: "The English manufacturers won't send out the goods, so we do it, and make the profit." Mr. Cusack Smith says that this only emphasises the folly of "not sending out British travellers," and he declares that British trade will suffer far more severely during the next five years from German competition than it has done already, unless British manufacturers attack the colonial and foreign markets in the energetic, well-organised, up-to-date, and conciliatory manner adopted by the Germans.

A financial contemporary the other day remarked, in connection with this matter, that it is not easy to understand why British manufacturers should be so slow to act upon the advice, in the main sound and practical, conveyed through the medium of our consular reports. German houses go in for a very high standard of education for young men who lay themselves out for commercial pursuits, and our consul at Stettin recently drew attention to the great service rendered in this direction by the Stettin Commercial Association, which was opened about 27 years ago. One of the objects of this association is to send young men out abroad to the British colonies, America, and elsewhere, to improve their knowledge of business, and to work in the interests of Stettin trade, a free grant of about £75 being made to each man for the purpose. At least 50 of these grants have been made, and the German consul of each country visited was informed of the arrival of the student. Here is a form of organised competition which might do untold harm to the business of this and other countries. It should be well digested by Englishmen. What can be the value of mere circularising in the face of such facts as these?

American houses by no means ignore British consular reports, and for that reason we can hardly afford to completely ignore theirs. The American Resident and Consul-General at Bangkok recently addressed some important remarks on the trade opportunities of Siam, a part of the world, by the way, which receives some attention at the hands of American electrical contractors. He draws attention to the splendid field offered for development, and advises special efforts to be made to increase the trade of the United States with this rich and prosperous kingdom of South-Eastern Asia. A critical period is approaching, and the results thereof will determine the control of Siamese foreign trade.

The report says that exporters of Europe have fully awakened to the importance and possibilities of Siam's markets, and adds:—

"After a residence of four years in Siam, I think that here is one of the best opportunities for the United States to build up a trade that is afforded anywhere in the world, considering, of course, the population and area. But all efforts to induce American exporters to enter these markets have been unsuccessful. Letters have come in unlimited numbers, to all of which careful attention has been given; catalogues have arrived and been distributed where they would do the most good; questions asked have been answered in detail; and many reports, general and specific, have been sent to Washington and duly published for the benefit of the exporters and manufacturers of the United States; but still there is a most discouraging lack of interest. This interest should be evidenced by sending to Bangkok experienced and capable representatives to carefully investigate the field, secure trial orders, and establish reliable agencies. In this connection, three facts are worthy of note: First, not more than six qualified representatives of American houses have visited Siam during the past three and a half years; second, almost without exception those that have come have been surprised at the extent and opportunities of the market, and have gone away with satisfactory orders, or, at least, with sufficient to pay expenses; third, in the same period no less than 100 capable representatives of European firms have visited Bangkok, and, in 90 per cent. of the cases, have done very well.

"Catalogues are valuable in their way—invaluable, in fact—but too much reliance is placed on them. They do not discuss the matter with the buyer; they do not answer all his inquiries; they do not obviate his objections to trying a new firm, a new class of goods, or to giving up his relations with some European house which has supplied him for years. If firms which are rich enough to publish the elaborate catalogues, which they issue annually, would devote even a small portion of that expense to sending energetic, educated, and tactful representatives to the far East, they would obtain far more substantial returns."

Some important facts are mentioned in the *Consular Journal*. It is to be hoped, says our contemporary, that our electrical engineers and our public works contractors are fully alive to the field for enterprise which China is now affording. It is, of course, too much to expect that China will now awaken completely from the comatose condition in which she has lain for centuries, but that she is exhibiting greater signs of vitality, owing to the action of the Powers, than she has ever done before is not to be denied. Her rulers are, it seems, learning to appreciate the truth of the scriptural injunction that it is no use kicking against the pricks, and European enterprise has pricked her coast-line sorely of late. The municipal authorities of towns like Shanghai, Pekin, Tientsin, &c., are therefore taking steps to establish electrical tramways, and tenders will presently be invited for undertaking these works. The Shanghai authorities, says a Consular correspondent writing to us, have already adopted the following resolution: "That the Council be, and is hereby, authorised to consider the expediency of establishing a system of electric tramways in the settlement." Our contemporary's correspondent urges electrical and other engineering firms to send out representatives or appoint agencies.

Langdon-Davies Motor.—The business of the Davies Motor Company, of 16, Red Lion Street, Clerkenwell, has been transferred to the Langdon-Davies Electric Motor Company, Limited. This company has taken premises at 101, Southwark Street, S.E., where there is every facility to enable them to cope with a fast increasing business. The entrance floor of the building affords room for spacious showroom and offices, and in the other parts of the building there is ample space for the manufacturing department. The workshops are equipped with machine tools and special labour-saving appliances of the most up-to-date character.

London School Board.—The Industrial Schools Committee has been authorised to obtain tenders for the supply of an auxiliary engine, dynamo, and switchboards, and connecting up circuits for direct lighting on the *Shaftesbury* training ship. The engineer's estimate is £950.

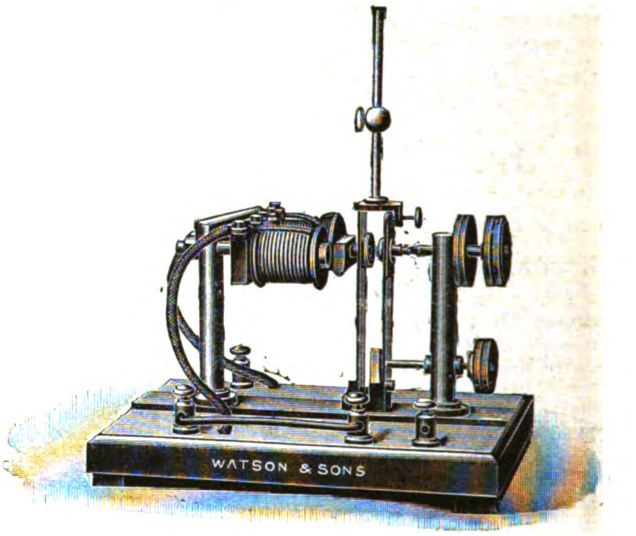
The Microphonograph.—From Mr. G. A. Nussbaum, of 29, Ludgate Hill, who represents La Société Industrielle des Téléphones in this country, we have received a pamphlet describing the new microphonograph which that company has recently brought out. The pamphlet contains an illustrated and general description of the Dussaud microphonograph (Berthon-Dussaud-Jaubert system) and its applications in the treatment of deaf mutes. Some of the illustrations show deaf mutes who are in the seventh heaven of delight upon discovering that by the aid of the microphonograph they are enabled to hear musical and other sounds.

Mill Lighting.—Messrs. W. H. Baughan & Co., of Charlbury, have secured the order for a complete installation comprising dynamo, shafting, accumulators, &c., of the new mills of Messrs. Early & Sons, blanket manufacturers, of Witney.

Personal.—Mr. John Shaw, electrical engineer, of Manchester and Ashton-on-Mersey, has just been elected chairman of the Ashton Urban District Council, and he will thus be entitled to sit on the Bench as a Justice of the Peace for the County of Chester. Mr. Shaw has been a member of the Council since its formation, and in that capacity was enabled to render excellent service when the mains for the electric light now supplied by the Altrincham Electric Supply, Limited, were laid down for the supply of the township. Mr. Shaw was also elected a member of the Sale and Ashton Technical Instruction and other Committees.

Smoke Nuisance.—At Greenwich Police Court on Thursday, the Crystal Palace District Electric Supply Company, Limited, and Mr. B. G. Blanchard, their secretary, were summoned in respect to a nuisance arising from black smoke issuing from a chimney at their works. The offence was admitted by Mr. Dumas who asked for the summons to stand over so that the company might provide other apparatus and get smokeless coal. Mr. E. Wright, clerk to the Lewisham Board of Works, said the Board would agree to this course, and the magistrate adjourned the case for a fortnight.

The "Vril" Contact Breaker.—The "Vril" Contact Breaker for induction coils is the invention of Mr. James King, A.I.E.E., and the sole right of manufacture has been acquired by Messrs. W. Watson & Sons, of High Holborn. The apparatus is claimed to afford many advantages to workers with Ruhmkorff coils. It can be supplied to almost every make of existing induction coil. It is claimed, among other things, that the construction is such, that it gives a prolonged period of contact, affording the necessary time for the thorough magnetic saturation of the core, combined with a very sudden break. The results obtained with the ordinary vibrating break are said to be yielded by the "Vril" with 50 per cent. less battery power, and with 25 per cent. less battery power than is requisite to run the ordinary vibrating break, 15 per cent. more spark length is



yielded by the coil if the "Vril" Contact Breaker be employed. The heating of the platinum contacts is greatly diminished, and does not become very appreciable with a long run of 30 minutes or more; liability to adhere is obviated, and the wear of platinum very much reduced. Workers with Rontgen's X rays will especially appreciate this feature. The speed of the make and break is controlled by means of an adjusting screw. The "Vril" affords facilities for varying the speed of the vibration exactly. It produces the same effect as a mercury interrupter, without any of its trouble and annoyance. The figure shows the breaker mounted on a separate case unattached to the coil.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The Gas and Electric Lighting Committee reported to the Town Council on Tuesday, recommending that the electricity mains should be extended to the West End, and that the low tension direct system, with drop of 110 volts at full load, should be adopted, at an estimated expense of £5,750, as recommended by Prof. Kennedy. The Committee suggest that it be remitted to the engineers to prepare specifications and invite tenders for the work. The Committee did not see their way to recommend the Council to take any action in regard to dust destructors at present.

Barrow.—Mr. R. H. Burnett, the borough electrical engineer (late of St. Pancras), commenced his duties on Monday last.

Basingstoke.—The Electric Lighting Committee, after considering terms proposed by Messrs. Warburg, Dymond & Co., for putting down an electricity installation, has recommended the Town Council to apply for electric lighting powers themselves for carrying out the works. This course was approved by the Council.

Bedford.—The Bedford Town Council have decided to increase, by £1,400, the amount of the £4,000 loan they are about to apply for, the addition being made expressly in order that the electric light may be installed on the Market Hill.

Bermondsey.—At Monday's Vestry meeting the report was considered of the sub-committee, which appeared before the Board of Trade on April 27th, when the opposition of the London Electric Supply Corporation, and the County of London and Brush Provincial Electric Lighting Company, to the Vestry's application for an electric lighting provisional order, was heard by Sir Courtenay Boyle. The Committee reported that after the opposition had been heard, Sir C. Boyle asked whether the Vestry intended to carry out the order if granted, and on being assured by the chairman of the Electric Lighting Committee that such was the case, Sir C. Boyle said that the Vestry could have no objection to the deletion of the clause which empowered the Vestry, with the consent of the Board of Trade, to transfer its powers; and this was accordingly agreed upon. Sir C. Boyle advised the Vestry to again consider the financial aspect of the question, and stated that if within 14 days the Vestry decided to go on with the order, he would recommend that the same be granted. The sub-committee recommended that Sir C. Boyle should be informed that the Vestry, after again considering the financial question at his suggestion, respectfully asked that a provisional order should be granted to the Vestry. This recommendation was unanimously adopted.

Bromley.—The Bromley (Kent) Electric Light and Power Company, Limited, who have just acquired the powers formerly vested in the local authority, have, within the past week, made a practical start. A contract has been entered into for the erection of a central lighting station, and at the present time workmen are busily engaged in preparing the foundations. Many of the shareholders are tradespeople and private residents, who have given notice of their desire to be supplied with the light. The contract for the installation has been secured by Messrs. Edmundsons, of Westminster, and one of the first places to be lit is the new Bell Hotel, now approaching completion. The Bromley Company have also entered into a contract with the newly-formed Chislehurst Electric Lighting Syndicate to supply them with current. The secretary of the Bromley Company is Mr Martin J. Dickins, of the Market Square, Bromley, and, notwithstanding the difficulties experienced in acquiring possession of the order, the future of the company is generally regarded as most hopeful.

Canterbury.—Good progress is now being made with the work connected with the establishment of the electric light here. The whole of the contracts have been settled; the construction of the generating station is well in hand, and the laying of mains is to be commenced in a few days. At the meeting of the Town Council this week the Lighting Committee submitted a schedule of the proposed positions and number of incandescent lamps to be used in public lighting. There are to be 144 on posts and 29 on brackets, the latter of a design costing £3 1s. 10d. a piece. The Committee recommended that the main thoroughfare from St. George's Gate to Westgate be illuminated by means of arc lamps, 12 in all, at an additional cost of about £140. Six separation stations are also to be provided for lighting and extinguishing the arc lamps, at an outlay additional to the estimate of about £707 10s. The contract for wiring the new Reaney Institute for the electric light has been secured by Mr. E. J. Philpot. It is hoped to have the light in use by next winter.

Chorley (Lancs.)—The Corporation have obtained a provisional electric lighting order from the Board of Trade.

Colchester.—The electric light station is to be opened about the month of July.

Colombo.—The contract for the lighting of the public streets and roads of the Fort of Colombo has been given to Messrs. Boustead Bros.

Dewsbury.—The 69 applications for the position of electrician to the Dewsbury Corporation has been reduced from six to three by the Electricity Committee. The final selection will shortly be made. The salary is £250 a year.

Dublin.—The Dublin papers say that on Wednesday evening last week there was a failure in the electricity supply, a number of hotels being seriously inconvenienced. The *Daily Nation* says that "the failure was occasioned by the breakdown of three different engines." That paper also says that several of the hotels are about to take legal proceedings against the Corporation.

Dundee.—The Gas Committee has recommended that the estimate of a Dundee firm be accepted for erecting a new economiser house at the electricity works at £600.

Durham.—A local correspondent says that from Wednesday's Town Council proceedings it would appear that incandescent gas will be adopted for street lighting. The matter of electric lighting *v.* incandescent gas is in the hands of a committee.

Eastbourne.—On Monday the Eastbourne Town Council decided to consult Mr. Wright, the engineer to the Brighton Corporation, anent the public electric lighting works being combined with the destructor. Mr. Wright will be consulted either alone or in conjunction with another expert, who had been approached by the Committee.

Edinburgh.—The Electric Light Committee's provisional estimates for the year ending May 15th, 1899, shows:—Estimated expenditure for 1898-99, £49,250, and the revenue £51,250, leaving a surplus of £2,000 to be transferred to the credit of the rates, after providing £6,000 for reserve fund. Last year the estimate was £33,390, and the revenue £35,455, leaving £2,065 to be credited to the rates, and after providing for £4,000 to be contributed to the reserve fund.

Glasgow.—The Electricity Works Sub-committee recommends the Corporation to adopt proposals which have been brought forward by Mr. Chamen, the borough electrical engineer. The statement, which comes before the Electricity Committee shortly, says that the Waterloo Street station, with its capacity of 3,300 horse-power, was completely overloaded during the fog last winter, and as the increase in the number of lamps fixed had been, on an average of five years, about 30 per cent., this meant, with the erection of over 100 lamps on the Springburn electric tramway route, a necessity for at least 100 horse-power additional. Waterloo Street station being taxed to its utmost capacity, a new site had been purchased at Port Dundas, where work had already been begun, and arrangements had been made for the purchase of another site for a generation station on the south side of the river, near Eglinton Street station. At Port Dundas there would be no difficulty in installing some 30,000 horse-power, and at the southern station another 15,000. The question of distribution had also to be considered. Waterloo Street station was at present distributing current at a pressure of 100 and 200 volts, but the Board of Trade regulations now permitted current to be supplied at 250 and 500 volts, which enabled the current to be carried much farther, and saved very largely in the amount of copper required in the distributing mains and feeders, the saving being about 50 per cent. The new plant already ordered for Port Dundas was designed to supply current at the increased pressure, and the plant for the southern station could be similarly designed. There would be no difficulty in supplying feeding points about two miles distant from each of the new generating stations, and in further supplying an area of about half a mile radius from such distant feeding points. This area practically included the whole municipality, so that there would be no necessity for resorting to high tension current. The use of the increased voltage rendered it impossible to work the new stations in connection with the same mains which at present distributed the energy from Waterloo Street, and so it would be desirable in time to relieve that station of its entire load. The capital expenditure detailed in the report is £551,000, made up as follows: Capital expenditure at present, £150,000; capital expenditure proposed in report, £396,000; cost of removal of Waterloo Street plant, £5,000. The surest way to arrive at a low rate of charge for the supply of electric light, concludes Mr. Chamen, is to make the concern as large as possible, so that the sooner the capital expenditure contemplated in the report is reached the better. He therefore recommends (1) That in addition to the £95,000 to which the Corporation already stand committed, a further expenditure of £61,000 be authorised for the Port Dundas station and mains, and (2) that an expenditure of £108,000 be authorised for the South Side station and mains. The expenditure would be spread over a period of about two years.

Glossop.—A special meeting of the Town Council discussed the electric lighting question last week. A sub-committee of investigation was appointed, with power to engage a consulting engineer. The meeting was adjourned to June 5th, when the question of applying for the provisional order will be dealt with.

Heaton Norris.—The District Council has resolved to apply for a provisional order.

Hereford.—The Electric Light Committee has been empowered to take the necessary steps for providing the electric light for the town. Expert advice will be obtained, and inquiries made *re* site, and on the subject generally.

High Wycombe.—Last Saturday the foundation stone of the electric lighting station buildings was laid by Councillor Wood (chairman of the Electric Lighting Committee of Wycombe Corporation). The company which has been formed to carry out the work is entitled the High Wycombe Electric Light and Power Company, Limited, Mr. Alfred Slatter being the managing director. A site for the electric light station was found in a meadow adjoining Lily's Walk. The buildings have been designed by Messrs. Moxham and Son, of Wycombe, and include a boiler house, engine house, accumulator house, and various offices. The contract for their erection has been entrusted to Mr. Henry Flint, whose tender amounted to £2,383. The contract for the electrical plant has been placed in the hands of Edmundsons Electricity Corporation, Limited, under the supervision of Mr. J. C. Wigham, and of the resident engineer, Mr. Fippard. It is hoped that supply will be ready by July 1st.

Hornsey.—The provisional order has been granted by the Board of Trade with slight alterations.

Hull.—The Electric Light Committee, on 28th ult., decided to recommend the Council to extend the electric light installation of the city into East Hull, at an estimated cost of £25,000. When the extension is made, the circuit of the city will have been completed.

Ilford.—Mr. Hawtayne is to survey certain lands in the district with a view to selecting a site for electricity works.

Islington.—As we have seen several mis-statements regarding the success of the Islington electric lighting undertaking, the following notes will be interesting as being the facts of the case. The Vestry has spent £144,226 capital up to December 31st last, and is now spending a good deal more. The *net loss* last year was £318. The *gross profit* was £4,432, and these figures are good for a business in its second year. The total cost per unit is 3 57d., and to this has to be added interest, &c., amounting roughly to 6 per cent. on the capital invested. As a matter of fact, long before the supply commenced the price of current was fixed, and for public lighting it is 5d. per unit. This covers all charges for current, interest on capital of lamps, &c., repairs to lamps, &c., trimming, erection, management, &c. The 1½d. per unit over works' costs does not quite pay all these charges, so that the supply is quite reasonable at 5d. per unit, and Mr. Hulland, the chairman of the Hackney Electric Lighting Committee, is quite wrong in assuming that the books are balanced by a "cooking" process. Every arc lamp at Islington costs £30—£40 total including *all* costs, as explained above. The Works Committee pay 5d. per unit, and that is all; the Electric Lighting Committee find all plant, labour, lamps, &c, and do all the work, light the streets, &c., and get the sum mentioned as return for *all* and every expense incurred in so doing.

For the quarter ending March 31st, the receipts for the supply of electric light in Islington amounted to over £6,000. The estimated cost of production was £2,700, leaving a gross profit of £3,300. After deducting repayment for loans, there is a net profit of £1,750.

Keighley.—The Corporation is about to approach the electric light question in earnest. A visit was paid to Southport last week, and a provisional order is being applied for.

Lancaster.—The Town Council resolved on April 27th, upon the recommendation of the Electricity Sub-Committee, that the tender of Messrs. Willans & Robinson, Limited, for the supply and erection of a close-type high-speed engine for the electricity works (£1,347) be accepted. The Committee were authorised to accept tenders for a dynamo. Applications for the supply of electricity to Ripley Hospital, the Royal Grammar School, and Bowerham Board School, were granted, subject to guarantees being made that the income from each building would be equal to 15 per cent. on the outlay. With the exception of a few churches, all the principal buildings in Lancaster are now lighted by electricity.

Liverpool.—The Lighting Committee last week agreed upon extensions of mains in various streets at a cost of £800.

Ludworth.—The Parish Council has appointed a sub-committee to inquire fully into the subject of electric lighting.

Mexborough.—The ratepayers will oppose the scheme of the General Power Distributing Company, as in a year or two the district may put down its own plant.

Mitchelstown.—Major Cardew held a Board of Trade inquiry last week regarding the application of the Guardians for a provisional order to light the town with electricity. Mr. Richard O'Driscoll, engineer to the scheme for the Board of Guardians, gave evidence as to the manner in which it was proposed to light the town. The stream from which they proposed to derive the motive power had a horse-power of 17½ on an average. The stream varied very little, though it was occasionally flooded in winter. The average fall in the level would be 3 or 4 feet at the very outside. Major Cardew, quoting from an estimate made by Mr. Harris, of Bray, said he noticed the amount estimated for cost was £825. He afterwards visited the stream, and pointed out that considerable expenditure would be necessary in the making of embankments, and expressed an opinion that a cheaper scheme of public lighting than that now proposed could be adopted with advantage to all parties.

Morley (Yorks).—At Tuesday's meeting of the Corporation Mr. Robert Hammond submitted his report on the progress of the electricity works, which has now been in successful operation for some time. The motor alternator has been returned to Wolverhampton for alteration to the bearings. Mr. Hammond was hoping to be in a position to report that the final tests of the plant had been completed this week, but the contractors have asked to be allowed a few more days' delay. The apparatus for measuring the water is ready, and there is now nothing to prevent the tests taking place at an early date. In accordance with instructions, Mr. Hammond submitted a statement made up to March 31st, showing the commitments on capital account sanctioned by the Local Government Board, £22,500; commitment to date, £20,764; balance of the original scheme still available for mains, extensions, connecting up customers, &c, £1,735 10s. 2d. In November last year, in accordance with the request of the committee, he presented a report on the electric lighting of all the streets through which the mains are laid, and then pointed out that immediate decision on the matter was not necessary, as cable ducts were to a large extent available for accommodating the necessary mains without re-opening the streets. The committee ultimately resolved to order cable for connecting the present arc lamps direct to the sub-stations, instead of the general distributing mains, but to defer consideration of the remainder of the scheme until the works were completed and in operation. Mr. Hammond again brings forward a scheme for the general lighting of the streets where mains are laid. In his previous report he deprecated a mixed scheme of arc and incandescent lighting, and set forth the cost of either type of lighting by itself, for each section under consideration. An extension of the arc lighting might be desirable in South Queen Street and Chapel Hill, but the remaining sections could be best dealt with by means of incandescent lamps enclosed in glass lens refractors, as at Brighton, Ayr and elsewhere. Mr. Hammond recommended that a trial lamp or two on this system should be fixed in some favourable spot for actual experiment. Mr. Hammond then concludes his report by giving his scheme for lighting, which will cost, with special mains, £650, and without special mains, £575.

Portsmouth.—It is proposed to purchase certain property in St. Mary's Street, Portsmouth, adjoining the electric light station, the space being required for extra machinery.

Preston.—The National Electric Supply Company has reduced its charges for lighting current. The company has adopted 220-volt distribution. After July 1st the price will be reduced from 7d. to 4d. per unit after one hour's use, less 15 per cent. cash. Current for heating and motive power purposes will be 3½d. per unit net.

Provisional Orders.—The Electric Lighting (Provisional Orders No. 1) Bill relating to Airdrie, Brechin, Hamilton, and Rothesay was read a second time in the House of Commons last week.

Ryde.—The Board of Trade have decided in favour of the Corporation *re* the Electric Light and Power Company, and consequently the latter will not proceed with their application for powers to supply electricity to the island borough.

Sheffield.—Judging from the correspondence and comments in the local press, and also the discussion in the Council Chamber, it appears to be true that the public meeting at which the proposed purchase of the electricity undertaking was disapproved, was really "packed" by ironmongers and other tradespeople who might be justly termed interested parties. It seems, therefore, that the poll which is to be held is quite unnecessary, yet it must now be held at a cost of about £1,000. Mr. T. Scott Anderson (of the local electrical firm Scott Anderson & Beit) writes to the local press to say that his firm had nothing to do with the opposition. He says, however, that he, as president of the Contractors' Association, wrote to the Town Clerk asking for particulars as to the Corporation's proposals regarding the clause which gave it the right to manufacture and trade, but to the question whether the Corporation would not compete with ordinary contractors no answer was forthcoming. He questions whether six of the votes at the public meeting could be said to be electrical. He considers the Corporation itself is only to blame, as it has known of the opposition for some time past.

Shoreditch.—At the fortnightly Vestry meeting on Tuesday, Mr. H. Winkler again raised the question as to when the electric lighting accounts, which had been promised, would be placed before the Vestry. In his opinion it was desirable that the accounts should be forwarded generally to the members of the Vestry without going specially before the Lighting Committee. In answer, the accountant stated that the accounts were in the possession of the printers, and that he hoped to have corrected copies ready for presentation to the Lighting Committee on the following day, so as to be brought up at the next Vestry meeting. On behalf of the Electric Lighting Committee, Mr. H. E. Kershaw said they had no feeling in the matter. If the Vestry desired to have the accounts before going before the Committee it could have them; but as it was purely a Committee matter, he thought the figures should go before the Committee in the first instance. The discussion on the subject then terminated. The Lighting Committee announced that they had considered a report from the chief engineer to the effect that he had received three proposals from three insurance companies as to insuring the engines. It was resolved to insure the six engines with the National Boiler Insurance Company for £200 on each engine, at a total premium of £49 13s. The same Committee had had under consideration a report from the chief engineer (Mr. Russell) as to whether it was right to charge the capital cost of the arc lamps and posts to the electric lighting capital account, or whether same should be paid for out of the general rate, as in the case of gas lamps, as some of the work in connection with painting same had been charged to the general rates. The Committee recommended and the Vestry decided that the cost of the arc lamps, columns, &c., should be paid for out of the general rate.

Shoreham.—The Local Government Board is prepared to sanction the £6,000 loan for electric lighting if the District Council obtains the necessary powers, submits plans, and complies with the usual conditions as to information. The Council, on receipt of this intimation on Tuesday, decided to leave the matter in abeyance for the present.

Singapore.—A draft scheme has been submitted to the municipality by Messrs. Moine & Co. for electric tramways and the electric lighting of Singapore. The proposal, says *Indian Engineering*, will be taken into consideration in due course, and if vested interests do not intervene, the Settlement will make a necessary advance in its development.

Southampton.—Last week the Council adopted a report of Mr. Manville's, submitted by the Electric Lighting Committee, in which he recommended public lighting by 62 2,000-C.P. arc lamps for various streets. The standards will also be provided with brackets for two 32-C P. incandescents for lighting when the arcs are extinguished at midnight. Thirty-two of these lamps will be used in the streets in which both electric lighting and tramways will be combined, and some of the standards will be arranged for both purposes and some for lighting only. Tenders are to be invited for the supply of the steel and iron columns recommended. It is expected that the streets will be electrically lighted by September.

Southport.—The report of the Gas Committee shows that electricity is rapidly superseding gas in that town as an indoor illuminant. The profits on gas for the year have only amounted to £7,000, or £4,000 less than was estimated.

Stafford.—The annual report of the Corporation Electricity Department shows that the consumption of electricity for the 12 months ended March 31st amounted to 52,231 Board of Trade units, as compared with 39,606 units last year, being an increase of 12,625, or nearly 32 per cent. The manager has submitted a short report upon the advisability of doubling the present pressure of the electric supply, and he was authorised to confer with Dr. Hopkinson, and report fully upon the question at the next committee meeting.

St. Helen's.—The Electricity Committee recommends the erection of arc lamps in a number of streets.

St. Pancras.—A very satisfactory statement was placed before the Vestry at the meeting held on Wednesday last week by the Electricity and Public Lighting Committee, in regard to the working results of the electric light works during the year ended December 31st, 1897. The Committee reported that the total revenue for the year amounted to £33,347 19s. 11d., which is an increase over the year 1896 of £6,258 3s. 6d., equivalent to more than 22 per cent. The net profit amounted to £6,517 19s. 9d., which, after writing off the deficit of £800 12s. 7d. brought forward from 1896, left a net profit for the year 1897 of £5,717 7s. 2d. The Committee recommended the Vestry to forward copies of the accounts to the Board of Trade and the Local Government Board, and that from the profits a sum of £4,000 should be transferred to a reserve fund, and that the balance of £1,717 should be carried forward to the accounts for 1898. In moving the adoption of the report, Mr. H. J. Menzies (chairman of the Committee) complimented the Vestry on the very satisfactory results, as exemplified by the accounts, which showed that the early anticipations in regard to the electricity undertaking were, in the main, being fulfilled. If the enterprise had been of a private nature, the past year's results would have yielded a dividend of 6 per cent, and allowed of £3,000 being carried to the next account. The works had sold a larger quantity of current, which had been generated at a lower cost than in previous years. In three years the revenue from private lighting had been doubled, and the undertaking was still growing. The speaker thought it right that the labours of the staff should be recognised. If the stokers had not quite fully earned the bonus promised to them he hoped the Committee would take their case into consideration and make some recommendation. The Vestry should also recognise the work of Mr. Sidney Baynes (the chief electrical engineer), and that of Mr. A. E. Pycraft (chief clerk of the electricity and public lighting department). The Committee, the speaker concluded, could at last see clear water, and he hoped that the confidence placed in them would not be unappreciated.

Tipton.—The District Council has decided not to withdraw its objections to the scheme of the Midland Electric Corporation for Power Distribution. The Council could not agree to the rates proposed to be charged to them by the company.

Wells.—The provisional order of the Wells (Somerset) Town Council expires in July next, and the Council at their meeting on Monday decided to apply for an extension of time. The Gas Company have fitted incandescent lights throughout the town, but during a gale lately they suffered severely.

West Ham.—The Council has issued a notice to the effect that it will commence to supply electric current in various thoroughfares on September 29th.

West Hartlepool.—The Town Council on Tuesday instructed the borough surveyor to forthwith invite tenders for taking out the quantities for the electric lighting station, and ask for the shortest time in which they can be ready; and that upon acceptance of a tender by the committee, he at once advertise for tenders for the plant. The Local Government Board has sanctioned the application to borrow the money, and the Board of Trade has approved of the system. The Mayor remarked that negotiations were proceeding with the tramway company in regard to the light railway to Seaton Carew, and also in regard to the town supplying electricity to drive the trams. He thought the matter would be settled and an agreement signed before long.

Wormit.—A public meeting last week considered the question of introducing electric lighting into the village. A scheme was brought forward by a Mr. Cowley which would cost, for buildings, plant, &c., £3,000, and an annual expenditure of £335. It is interesting to note that a recent canvass of the district showed one ratepayer to be in favour of gas, 12 oil, and 77 electric light. The meeting adjourned for a week, and a committee is to be appointed.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Algeria.—The first line of electric tramway in Algiers was put in operation on 19th ult. The line, which is 10 kilometres long, extends from Bad-el-Oued to Mustapha.

Birkenhead.—The Special Committee appointed to inquire into the question of tramways in the borough issued a report for presentation to the Council on Wednesday. The Committee report that they have been unable to come to any arrangements with the Birkenhead Company as to the surrender of their lease, which expires at the end of 1900, and they had not thought it necessary to negotiate with the Wirral Company, whose lease expires in 1916. Applications had been received since the closing of the negotiations with Mr. Ross from several bodies desirous of running electric trams in the town, but all had been declined on account of the Council's decision in regard to Mr. Ross's proposal. The Committee have unanimously decided that a more extended system of lines should be laid down for electrical trams on the overhead system, and they consider that the Council should settle upon the routes as soon as possible, and they have drawn up a scheme to submit to the Council, so that work might be decided upon and begun as soon as necessary. In arriving at their recommendations as to routes the Committee have carefully taken into account the following general points:—(1) Suitability of the road, *i.e.*, as to probable traffic, interception of branch or side roads, gradients, widths, &c. (2) Possibility of profitable and useful future extension. (3) General requirements of a district. The routes proposed are the Borough Road line, the Dock line, the Higher Tranmere line, the Shrewsbury Road and Oxton line, the Park Road North line, and the Central Claughton line. The surveyor (Mr. Charles Brownridge) estimates that the expense of relaying existing lines, where utilised, and laying down new lines will be about £104,500, and the wires, poles, cars, and installation will be about £77,500.

Bradford.—Some quick work in cable laying was performed between 11 p.m. last Saturday and 6 p.m. on Sunday, in laying the feeders for the Great Horton section of the Corporation electric tramways. The cables were laid by the staff of the electricity department of the Corporation. Four large mains were put down with a sectional area of 1·6 square inch of copper, together with a telephone cable for the tram service, and a "pilot wire" for recording the pressure at different parts of the route. The greater portion of the work was finished for traffic on Sunday evening, a length of 330 yards being completed, equal to 1,980 yards of cable.

Bristol.—On Friday last week the Bristol Tramways (Electrical Power, &c.) Bill, and the Bristol Tramways (Extension) Bill were read a second time.

Bromley.—The Mason's Hill, Bromley, residents strongly oppose the scheme for a light electric railway to be made in four sections, running from Herne Hill to Farnborough, through Dulwich, Sydenham, Penge, Beckenham, Shortlands, and Bromley. The promoters of the railway are the London Southern Tramways Company, Limited.

Ceylon.—Work in connection with the overhead trolley tramways is being pushed forward. Last month the rails were being laid, the power station erected, and part of the plant was ready to put in position. The span-wire system is to be employed.

Chatham and Rochester, &c.—The Light Railway Commissioners finished their inquiry last Saturday in reference to applications that have been made to carry out an electric tramway system for the towns of Rochester, Chatham, Strood, and Gillingham. Unfortunately, the opposition has proved too strong, and it does not appear that for the present anything further will be done in this respect, and thus a great boon has been lost to the whole neighbourhood. For some time past considerable dissatisfaction has been expressed by many at the present omnibus system, which is very inadequate, and it was thought, very properly, that a tramway system throughout the whole district (which comprises a large area of many miles, as all the towns mentioned adjoin one another, and has a population of more than 100,000) would be very beneficial. There was a great deal of evidence given for the trams. Foremost among the opposing parties was Mr. Thomas Aveling (managing director to Messrs. Aveling & Porter, engineers and steam road-roller and traction engine manufacturers). Their works are situated on the Medway's banks, at Strood. The firm employs nearly 1,000 men, and traction engines were constantly going in and out of the works daily. He maintained that the trams were perfectly impracticable in the streets, and would stop their business. Their firm turned out 360 engines in a year. They did a lot of work for the Dockyard and the Royal Engineer Barracks at Chatham, and he considered their engine traffic could not be worked with the trams. Of course the proprietors of the local omnibuses put in a strong opposition. For the purposes of the scheme it had been put forward that the tram company, if formed, would be prepared to assist the authorities to purchase certain properties in order to widen and improve the streets at necessary places. Numbers of people very greatly regret that the proposition has failed, as the district is being continually extended, and the trams would have been a great convenience to all classes.

Cheltenham.—At the Town Council meeting on Monday it was resolved to inform Mr. Bickerdike, of Montreal, Canada, who has applied for a franchise to immediately construct and operate a line or system of lines for electric cars, forming a complete service for the town, that if he likes to make a proposition the Council will consider it.

Colombo.—Work in connection with the construction of tramlines in Colombo is being pushed forward rapidly under the direction of the resident and consulting engineers, Messrs. Beveridge and Etlinger, sen. The poles for the trolley lines are erected.

Dover.—The contractor for the electric tramways permanent way has asked the Dover Town Council to remit the fine of £254 imposed on account of his contract not being completed to time.

Flamborough and Bridlington.—The promoters of the proposed light railway to Flamborough from Bridlington intend applying to the Light Railway Commissioners for an amendment of the order granted in 1897, to enable the company to increase the capital authorised to be raised, and to extend the time for the completion of the construction of the railway and works.

Holland.—Negotiations are in progress with reference to the conversion of the horse tramways in the town of The Hague into an electric line.

Kidderminster-Stourport.—The electric tramline which will start from the railway station in Comberton Road, and passes into the Stourport Road, following the line of highway, and terminating at the Stourport Bridge, will probably be opened by Whitsuntide. The boilers and engines have been put down, and one of the dynamos has been fixed. The cars, nine in number, are all at the depôt. Each car is constructed to carry 40 passengers, and fitted for electric lighting. Some of the cars are specially adapted for summer traffic, having open sides. Matters are so forward that in the course of a few days it is intended to have a trial trip along the line. A Dudley paper gives some notes on the present position of tramway affairs locally. The Light Railway Commissioners have made an order empowering (if it be confirmed by the Board of Trade) the British Electric Traction Company to make two lines—one from the existing tramcar line at Holly Hall to Kingswinford and thence by Wordsley to the bottom of Brettell Lane; another from Queen's Cross by way of Old Hill to the Five Ways at Cradley Heath. On both these lines the order provides for electric traction on the overhead system. The order has to be confirmed by the Board of Trade. Dudley Town Council has intimated its intention of opposing the order, so far as it deals with the portion of the routes within Dudley borough. Of course, the British Electric Traction Company will be represented by counsel at the Board of Trade inquiry, and backed by the other local authorities concerned outside Dudley, namely, Brierley Hill, Stourbridge, Rowley, and Amblecote Urban Councils and Kingswinsford Rural District Council. The inquiry will probably be held in a few weeks' time.

Leeds.—An interesting epitome of the working expenses and receipts for one week in connection with the Leeds overhead electric tramway system has just been published. The total receipts amounted to £656 16s. 4d., the mileage covered being 14,777 miles, the receipts per mile thus working out at 10·66d. The working expenses, depreciation, interest and sinking fund charges usurped 8·60d., thus leaving a surplus of 2·06d. per mile, or a profit of £6,595 per annum. The capital outlay up to date amounts to £138,374. Mr. E. Basil Lupton, a local solicitor, points out in a letter to the *Leeds Press* that the system has so far cost double the original estimate, and that the system is working at a loss. The figures at first sight show a profit; but he claims that an insufficient amount is taken off for depreciation, which should be 15 per cent., and not 7½ per cent.

The Highways Committee has resolved to recommend that the Headingley, Chapeltown, Dewsbury Road and Hunslet sections be equipped with the overhead electric system.

Limerick.—The firm of Zeitz, of Hamburg, are stated to have written to the Corporation in quaint English offering to establish an electric tram system all over the city "without any cost, on getting a lease of the streets." This is cool! We guess many an English promoter would like to get tramway concessions on these terms.

Liverpool.—The Tramways Construction Committee decided on Monday by seven votes to three, to order for use on the experimental electric tramway between St. George's Church and the Dingle 14 German electric cars—seven of the Altona type and seven of the Ring-Bahn type—with trailers to each. The cars, with their trailers, will accommodate 50 persons each. The Committee resolved to leave Sir Arthur Forwood to order 14 other cars from America, provided the specification of the electrical work was altered so as to fulfil the requirements of Dr. Hopkinson, consulting electrical engineer to the Corporation. About four months must elapse before the cars are ready for use. The Committee are desirous of seeing both the German and American cars at work, with the object of adopting a car of their own pattern which they hope to have made in Liverpool.

The City Council on Wednesday refused to agree to the recommendation of the Generating Stations Committee (of which Sir Arthur Forwood is the chairman) to accept tenders for the supply of electrical generating engines of a certain type, whereupon Sir Arthur intimated that he had striven during the last two years to provide the city with a worthy tramway system, but his Committee had not received the support and sympathy of the Council. He, therefore, not only would resign from the Committee, but that would be the last occasion upon which he would be present in that chamber. This is not the first time Sir Arthur Forwood has resigned from the Tramway Committee!

Newark and Worksop.—An important scheme is on foot to construct an electric railway between Newark and Worksop, which will run through a part of the far-famed Dukeries, so popular as a holiday resort. The line in many places will be laid along the side of the highway, and in others across land to be acquired for the purpose. The total length of the railway will be 22 miles 7 furlongs, and the gauge 4 feet 8½ inches.

Newcastle.—At a meeting of the Special Tramways Committee on Monday a discussion took place as to the two experts to be called in to advise on the cable and electric systems respectively. The resolution passed by the Council stipulated that these should not be financially connected with any tramway company or system of trams. Mr. Laws, city engineer, presented a report suggesting the following gentlemen as experts:—Cables, Mr. Callomb, Edinburgh; electric, Dr. Hopkinson, Mr. James Swinburne, and Mr. Manville. After a lengthy debate the matter was adjourned for a fortnight to enable members of the Committee to make further inquiries.

Nottingham.—The proposals of the Corporation to equip the tramways on the electric trolley system were referred to in our April 8th and 15th issues. On Monday last the following resolution was passed unanimously, and the Bill will accordingly be presented to Parliament:—"That the report of the Tramways Committee now presented to the Council be received and adopted as and for the second reading. That the Town Clerk be and he is hereby authorised, under the direction of the Tramways Committee, to take the necessary steps to obtain all such Parliamentary powers and the consent of the Board of Trade, and any other authorities as may be necessary to enable the Council to carry out the works mentioned in the said report, and that the costs to be incurred in so doing be paid by the Finance Committee in such manner as they may deem most expedient."

Paisley.—Detailed notice of the application which is being made by the British Electric Traction Company, Limited, for the construction and working of electric light railways within the counties of Renfrew and Lanark, is published in the *Glasgow Herald* of 23rd ult.

Portsmouth.—Notice has been given of the intention of the Hampshire Light Railways (Electric) Company, Limited, to apply to the Light Railway Commissioners for an order authorising them to construct and work light railways between Portsmouth, Cosham, Purbrook, Waterlooville, and Horndean. One line from Cosham to Horndean is about 5 miles, 7 furlongs, 3 chains in length, and the other, from Waterlooville along the road leading to Bargreen, about 5 chains in length. The gauge proposed is 4 feet 8½ inches, and the motive power electricity. Powers are to be sought by the company to generate, use, convey, distribute, and sell electricity either for power, lighting, heating, or any other purpose. Mr. A. W. White, J.P., manager of the Portsmouth Street Tramways, has taken an active part in promoting the scheme which is regarded with marked favour by the residents along the line of route, and especially at Waterlooville, a popular resort of Portsmouth people during the summer.

Ripon.—The City Council on 28th ult., had the question of tramways before it. The committee, which has been going into the question of the provision of better railway and tramway facilities, has been considering several schemes for cheaper transport between the city and the railway station, and proposed to visit Blackpool and Lytham to inspect the gas and electric trams; but in this the committee was overruled, the idea being considered premature.

Shanghai.—The Shanghai Municipal Council is considering the expediency of the establishment of a system of electric tramways in the streets of the Settlement, and "in its discretion to formulate scheme for ratification by the ratepayers by which the system be carried into effect."

South Staffordshire.—For some years past the local authorities in South Staffordshire have been agitating for an improved method of traction on the lines belonging to the South Staffordshire Tramways Company which traverse all the principal towns lying between Birmingham and Wolverhampton. At length the Board of Trade intervened, and in consequence of representations by the various District and Borough Councils, the tramway company have been pressed to substitute an improved method of traction for the steam engines at present in use. An important conference, convened by the Board of Trade, was held on Tuesday at the Town Hall, West Bromwich, to consider the question. All the local authorities in the district through which the company's lines pass were represented. Col. Marindin, of the Board of Trade, presided. Mr. Schuster, chairman of the tramway company, explained that they were promoting a Bill in Parliament, the cost of which would be borne by the British Electric Traction Company, the object being the introduction of an improved system of traction along the whole of the South Staffordshire routes. Mr. H. Ward, on behalf of the Handsworth authorities, opposed the overhead electric system, and suggested that a cable system should be substituted for steam engines, because passengers from the various Staffordshire towns would be able to travel to Birmingham without changing cars. Mr. G. H. Dunn (Mayor of Dudley) explained that in four years the lease of the tramways within their borough would expire, and then it was the intention of the Dudley Town Council to municipalise the tramways. Councillor S. Pitt, Mayor of West Bromwich, said, whilst his Corporation did not object to a further extension of the time for the use of steam by the company, yet they wished the Board of Trade to impress upon the company the necessity of improving the method of traction as speedily as possible. He thought probably the suggestion made by the Mayor of Dudley would be accepted by the other authorities, and if thought desirable they would take over the tramways, and then they could introduce what system of traction they liked. They thought, if they consented to a lease of the existing lines to the British Electric Traction Company for 21 years, it would prove disadvantageous to the interests of the local authorities. Mr. Sellon, of the British Electric Traction Company, explained that it was proposed to lay down the overhead electric system. Some of the shareholders objected to this, and preferred the conduit system. Ultimately the conference was adjourned for a month, and in the meantime Mr. Sellon undertook to supply the various authorities with full particulars of the Bill which it is proposed to promote in Parliament. The Wednesbury Town Council favour the introduction of the overhead electric system, which has proved satisfactory in other parts of the Black Country.

St. Helen's.—On 27th ult., a Corporation Committee received the Board of Trade's sanction to the £25,000 loan for equipping the tramlines and putting down plant. The inquiry into the matter was held only eight days previously by Major Cardew. The loan is to be repaid in 20 years. The Board was rightly thanked for its prompt and courteous attention to the matter.

Stockport.—The Stockport Corporation, who expect to be able to publicly supply electric light and power in the autumn, have approached the Stockport and Hazel Grove Tramways Company with the object of purchasing the concern and running electric tramways. At present the company shows no disposition to sell on the terms proposed.

The Surrey and Middlesex Light Railways.—The proposal of the London United Tramways Company to apply to the Light Railway Commissioners in June for powers to construct a light railway, with electric traction as the motive power, through Richmond, Ham, and Kingston, to Hampton Court, is threatened with severe opposition. The route proposed will lie through the residential portion of Kew Gardens, Richmond, over Richmond Hill, through Petersham, past the historical Ham House and the Dysart estates, to Kingston-on-Thames, thence over Kingston Bridge to Hampton Court Palace. In Queen's Road, Richmond, where the best class of houses in the borough are situated, the residents in the proportion of about 100 to two, have declared strongly against the proposal, the Parliamentary Committee and the Amenities Committee of the Richmond Town Council have recommended unqualified opposition, and the house agents in the town and the locality unanimously agree that the line if it came would ruin the place as a residential suburb. Upon the other hand, the Mayor of Richmond, a gentleman of close knowledge of the wants of the borough, and a good judge of its future, cannot definitely make up his mind upon the details of the proposal, and such local leaders as Sir Roland Wilson and Admiral Alington have expressed opinions in favour. A petition in Richmond assenting to the scheme has received 1,500 signatures, Avon-on-Kingston has received 2,000, and at Ham, Petersham, and Hampton numerous signatories testify their approval. In Ham and Petersham the public feeling is all in favour, the need of better means of communication being recognised. The Hampton Wick District Council have met privately, and their decision is kept a close secret; but several members have stated their approval of the scheme. At Kingston, the Town Council have referred the question, with the discussion, to their General Purposes Committee, but there is in the borough a feeling of satisfaction at the proposal. Mr. E. J. Halsey, chairman of the Surrey County Council, in the course of an interview, stated that he considered a tramway a great convenience, and he should support it, provided it was not unduly dangerous or inconvenient. The Ratepayers' Association, on the other hand, have met, and expressed the view that the Corporation and the borough should maintain tramways if they were wanted. The second proposal of the company to carry their line to Uxbridge is meeting with approval along the suggested route.

Volk's Electric Railway.—At yesterday's (Thursday's) meeting of the Brighton Town Council, the borough engineer and surveyor's report to the Works' Committee on Volk's electric tramway was considered. It seems that it will be necessary to reconstruct a part of the line on piles to the south of the new widened Madeira Road, the cost of this to Mr. Volk being estimated at £1,500. The Committee considered this a favourable opportunity for reconsidering the existing arrangement between Mr. Volk and the Corporation, and recommended the grant to Mr. Volk, at a yearly rental of £120, of a lease of the arch he occupies for his machinery, dynamo, &c., and a license for his line for a period of 21 years, subject to conditions for the proper maintenance of the line and such repairs as may be needed; the line, rolling stock, and plant, to become the property of the Corporation at the end of the 21 years.

Wednesbury.—The Town Council on Monday had a discussion *re* tramways. The Mayor said there was no doubt the tramways in that district were a great boon, and he considered it to be the duty of the authorities to do all they possibly could to prevent the stopping of the tramcars, and to give their best encouragement for improvements to be carried out. The electric traction adopted between Wednesbury, Walsall, Bloxwich, and Darlaston was very satisfactory, and he hoped the Handsworth and West Bromwich authorities would support the scheme, and adopt the same system in their respective districts. The overhead electric traction had been proved to be satisfactory, and preferable to the cable system.—Alderman Wilson Lloyd concurred.—The Mayor said whilst they were all desirous of the use of steam on the tramways being abandoned, they were most anxious that tramway traffic should not be stopped.

TELEGRAPH AND TELEPHONE NOTES.

Durham Telephones.—The County Council is of opinion that there should be telephone competition, but does not bind itself to support the New Mutual Syndicate.

Indian Telegraphs.—Mr. C. H. Reynolds, C.I.E., Director-General of Telegraphs in India, recently left Calcutta on a tour of inspection in East Bengal and Assam, whence he proceeds, according to *Indian Engineering*, to Simla, after inspecting some of the newly-constructed lines in the Punjab. A more thorough inspection of these lines is to be made by Mr. A. B. Larkins, Director of Construction. A committee is to determine the value of old telegraph stores dismantled from the field lines on the frontier.

Pacific Cable.—The opening up of China, through recent International developments, has led to the mooting of another proposal for a Pacific cable. It is suggested that a cable may be carried from Vancouver Island to some port in the Sandwich Islands or to Fiji, bifurcating thence to New Zealand and Hong-Kong. There is no doubt, says the *Standard*, that strong efforts will, in the present circumstances, be made in influential commercial quarters to improve both the steamship and cable communications with China.

Telegraphic Communication between Liverpool and the Continent.—Some correspondence has been passing between the Liverpool Chamber of Commerce and the General Post Office regarding telegraphic communication between Liverpool and the Continent. The following letter has been addressed by Mr. J. C. Lamb to the Chamber:—

"With reference to your letters of the 26th ult. and the 25th inst., and previous correspondence on the subject of telegraphic communication between Liverpool and the Continent, I beg leave to inform you that the proposal to use a new cable wire for the traffic between Liverpool and Hamburg was duly carried out, and this department has since been in communication with the German Administration in regard to the adoption of duplex-Hughes working between England and Germany. It has not been found practicable under existing circumstances to introduce duplex-Hughes working between Liverpool and Hamburg, but the experiments in this method of working on other circuits between England and Germany have proved so far successful as to afford ground for entertaining the hope that a similar result may ultimately be attained under the more difficult conditions applicable to the Liverpool-Hamburg circuit. I may add that the German Administration have intimated that they share the desire of this department to expedite the transmission of telegrams between Liverpool and Hamburg, and have expressed their readiness to substitute a copper for an iron wire on the inland section of the circuit in Germany if it is found that the working of the circuit would be improved thereby, and experiments will be made as to the effect of such an alteration as soon as certain new wires which are now under construction in Germany have been completed. With regard to the question of the transmission of telegrams from Liverpool to Bremen *viâ* Hamburg, instead of, as at present, *viâ* London, I have to state that the Liverpool-Hamburg circuit is at present fully occupied, and would be unable to carry additional traffic without delay. In any case the proposed alteration would not lead to any reduction in the number of transmissions, telegrams sent *viâ* London being only subject to two transmissions, viz., from Liverpool to London and from London to Bremen, while, if sent from Liverpool to Hamburg, they would have to be re-transmitted from the latter city to Bremen. Similar considerations apply to the suggested use of the route *viâ* Havre in preference to that *viâ* London for telegrams from Liverpool to Paris. It is feared that the suggestion that the former route should be tried experimentally for a certain time is not one to which it would be practicable to give effect. The question of the transmission of telegrams between Liverpool and France is, however, under consideration, and this department is in communication with the French Administration in the matter. I have to add that if certain experiments which will shortly be carried out yield satisfactory results, it is proposed to extend to provincial towns in England and France the telephonic service, which has hitherto been restricted to the two capitals, and in that case Liverpool would obtain the advantage of telephonic communication *viâ* London with Paris, and, where possible, with other French towns."

Telegraphists' Grievances.—A conference of M.P.s. and representatives of the Postal Telegraph Clerks' Association took place last week at the House of Commons. The matter will be brought up upon the discussion of the Postal Service estimates, and there will be supporters on both sides of the House.

CONTRACTS OPEN AND CLOSED.

OPEN.

Belgium.—May 25th. The date for the receipt of tenders for the electric lighting plant at the railway station at Ghent (Gand-Sud) for the Belgian State Railway Authorities has been fixed for May 25th.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Blackburn.—May 17th. The Committee of St. George's Presbyterian Church invites tenders for the electric lighting of the Church. See our "Official Notices" this week for details.

Dublin.—May 23rd. The Corporation wants tenders for the supply of high tension feeders and low tension distributors laid and jointed complete on a solid system, not including road work, but including the connecting up of existing consumers to the new mains. Also for transformers (20 to 50 kw., about 700 kw. in all) with instruments and apparatus in sub-stations erected and fitted complete. Particulars at the office of the city engineer; or from Prof. Kennedy, 17, Victoria Street, S.W. See our "Official Notices" this week for particulars.

Edinburgh.—May 6th. The Corporation wants tenders for the wiring of the St. Leonard's police station. Particulars from the resident electrical engineer, 5, Dewar Place, and see our "Official Notices" last week.

France.—May 21st. Tenders are being invited by the French Post and Telegraph Authorities in Paris for the supply, in 10 lots, of 111 kilometres of paper-insulated electric cables. Particulars may be obtained from, and tenders to be sent to, Le Sous-Secretariat, d'Etat des Postes et des Telegraphes, 103, Rue de Grenelle, Paris.

Great Eastern Railway.—May 12th. The directors invite tenders for the supply of stores and materials. For particulars see our "Official Notices" last week. Forms of application from the secretary's office, Liverpool Street Terminus, E.C.

London.—May 17th. The Bethnal Green Board of Guardians invites tenders for the supply of plant, and installing the electric light at the new infirmary, Palestine Place. Plans, &c., to be obtained from the architects, Giles, Gough & Trollope, 28, Craven Street, Charing Cross, W.C. See our "Official Notices" April 22nd for particulars.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

West Ham.—May 10th. The Council wants tenders for certain electroliers, standards, &c., required for its public buildings. Mr. J. J. Steinitz, borough electrical engineer. See our "Official Notices" last week for particulars.

CLOSED.

Blackpool.—The Corporation has placed the order for 120 rectified current double carbon lamps, with special switches, &c., with the Gilbert Arc Lamp Company, Limited, of Chingford. This order has been given out after careful tests.

Coventry.—The following tenders were submitted for wiring the new police buildings for the electric light, in accordance with specification prepared by Mr. Ram:—Ellis & Ward, £230; Drake & Gorham, £316 10s.; Veritys, Limited, £197 10s; Dobson and Curtis Bros., Limited, £187 17s.; Coventry Gas Fitting, &c., Co, Limited, £170; W. Tasker & Sons, Limited, £161 13s. Messrs. Tasker's tender was accepted by the City Council on the Watch Committee's recommendation.

Derby.—Messrs. Read, Holliday & Co. have secured the contract for wiring the Fore Street Yard buildings at £197.

Hampstead.—The tenders accepted by the Hampstead Vestry for electric lighting extensions plant are given by a daily contemporary as follows:—Siemens Bros. & Co., Limited, two 350-kilowatt steam alternators, Willans-Siemens sets, £7,100; S. Z. de Ferranti, Limited, two "Ferranti" switchboard panels, £111; John Brown & Co., two induced draught boilers, £4,850; John Fraser and Son, feed water heater, steam and exhaust pipes, &c., £911; also two duplex compound steam feed pumps, £895; Siemens Bros. & Co., Limited, a 50 kilowatt exciter in place of existing 23-kilowatt alternator, £910; less allowance for existing alternator, to be removed by and belong to the contractors, £300 = £610.

Hull.—Messrs. A. Bannister & Co. have secured a contract from the Electric Lighting Committee for the supply of Hickleton coal at 12s. 2d. per ton. Messrs. King & Co. have received the order to wire the Sculcoates Lane station.

Liverpool.—The Generating Stations Committee accepted the tender of Messrs. Willans & Robinson, Limited, for the supply of two compound engines and dynamos, at the price of £6,530 each, and one triple expansion engine and dynamo, at the price of £5,939.

London.—The London County Council received the following tenders for the supply of nine parapet lamp columns and lanterns, and four standard columns and lanterns for the electric lighting of Waterloo Bridge:—McDowall, Steven & Co., £189 12s.; W. MacFarlane & Co., £192 15s.; Young & Co, £250. The tender of McDowall, Steven & Co. is recommended for acceptance.

Newington.—The contract for the erection of the electric light works in Penrose Street at £12,928 has been given out by the Vestry.

Wallasey.—Eleven tenders were submitted for the erection and completion of extension of engine and boiler house at the Council's electric supply station in Sea View Road, Liscard, and that of Messrs. Hughes & Stirling (£3,077) was accepted.

FORTHCOMING EVENTS.

1898.

Friday, May 6th, at 8 p.m.—The Institution of Junior Engineers at the Westminster Palace Hotel. Paper to be read and discussed:—"Evaporative Condensers and Independent Air-pumps for Same," by Mr. Harry Fraser (member).

Monday, May 9th, at 8 p.m.—Society of Arts. "Electric Traction." Cantor Lectures by Prof. Carus Wilson. Lecture II.:—Acceleration—Conditions under which a train is started—Method of drawing acceleration curves—Uniform and accepted acceleration—Example—The City and South London Railway—Control—Comparison of different methods—How to ensure a smooth start—The series-parallel controller—Example—The Buffalo and Niagara Falls Electric Railway—Effect of the slipping of the driving wheels.

The Northern Society of Electrical Engineers.—Palatine Hotel, Hunt's Bank, Manchester. Paper on "Electric Elevators," by Mr. W. C. C. Hawtayne.

Tuesday, May 10th, 7 p.m.—The Institution of Junior Engineers. Visit to Messrs. Brin's oxygen works, Horseferry Road, Westminster, to inspect in operation Dr. W. Hampson's self-intensive refrigerator of gases.

At 8 p.m.—General meeting of the Röntgen Society, at 11, Chandos Street, Cavendish Square, W. Prof. Silvanus P. Thompson, F.R.S., in the chair. Papers will be read on "Notes on the Description of a New Induction Coil in ELECTRICAL REVIEW, February 4th, 1898" (with demonstration), by Mr. A. Apps, M.I.E.E.; and "Some Notes on Contact Breakers," by Dr. J. Macintyre. Discussion to follow.

Thursday, May 12th.—Institution of Electrical Engineers. Meeting at the Society of Arts (subject to the discussion on Mr. Andrews's paper being concluded last night). Papers on "A Magnetic Balance for Workshop Test of Permeability," by Prof. J. A. Ewing, F.R.S., member; and "The Registration of Small Currents used for Electric Lighting and other Purposes," by A. H. Gibbings, member.

Friday, May 13th, at 5 p.m.—Physical Society. Paper on "Galvanometers," Part II. By Prof. W. E. Ayrton and Mr. T. Mather.

NOTES.

Water-Tube Boilers.—A series of interesting trials with the New Haythorn water-tube boiler was concluded on the Clyde last week. With a three months' certificate from the Board of Trade the Caledonian Steam Packet Company fitted the boilers on board their paddle steamer, *Meg Merrilies*. The engines were compounded by fixing a cylinder of 24 inches in place of one of 42 inches. The pressure of the two tubulous boilers is 200 lbs., reduced by reducing valves to 130 lbs. at the engines. Although, says the *Times*, there is always a possibility of defects developing in boilers of the type, the success of the trials so far is marked, a speed of 14 knots being obtained with half the consumption of coal necessary formerly to get a knot less.

Jubilee of the American Association for the Advancement of Science.—Writing in the *Scientific American*, Horace C. Hovey says:—

Fifty years ago the American Association for the Advancement of Science was organised for the purpose of promoting intercourse between scientific men throughout the Continent, encouraging systematic scientific research, and increasing the facilities for more thorough investigation, and enlarging the usefulness of scientific labours. These ends have been sought by periodical and migratory meetings, by publications, by wide correspondence, and perhaps, most happily of all means, by encouraging genial and familiar intercourse between scientists. The completion of the first half century of this noble work will be celebrated in an appropriate manner in the city of Boston, August 22nd—27th, 1898, and the preliminary announcements for the jubilee are already made. The meeting will be held in response to the invitation of the Governor of Massachusetts, the Mayor of Boston, and the numerous scientific and educational institutions that cluster about that centre of intellectual life and activity. This cordial invitation was accepted at the Detroit meeting of the Association. The Boston Local Committee, now organised, includes a most distinguished list of names, among which we note those of his Excellency Governor Wolcott, as the honorary president; 25 presidents of universities, colleges, and other institutions, together with others of distinction as honorary vice-presidents; 129 members at large; Dr. Thomas Dwight, Prof. Alpheus Hyatt, and Prof. E. C. Pickering as honorary secretaries, and Col. H. L. Higginson as honorary treasurer. The latter gentleman is also the chairman of a strong committee on finance. The chairman of the Reception Committee is Dr. J. R. Chadwick, that of the Committee on Invitations is Dr. Henry P. Bowditch, that of the Committee on Excursions is Gen. F. H. Appleton, and that of the Executive Committee is Prof. W. T. Sedgewick. The local secretary, to whom all correspondence should be addressed, is Prof. H. W. Tyler, of the Massachusetts Institute of Technology, Boston, Mass. The Boston scientific Jubilee promises to be one of the most important and interesting assemblies of the kind ever convened. Many foreign scientists of eminence will take part in the exercises, and make addresses. Foreign educational and scientific bodies will send delegates, thus giving the occasion an international character. A number of "affiliated societies," really the offspring of the A.A.A.S., will meet during the Association Week, including those for the study of geology, chemistry, botany, forestry, entomology, mathematics, engineering, &c. All general and sectional meetings will be held in the halls and rooms of the Institute of Technology and of the Boston Society of Natural History. One day will be spent as the guests of Harvard University, one day in the historic city of Salem, and excursions are planned for the White Mountains, Cape Cod, and other regions of interest. Members who have allowed their membership to lapse are requested to renew their connection with the Association. A thousand new members are called for, and every scientific man in America is appealed to in order to make this Fiftieth Anniversary of a great Association a marked event in the intellectual history of our continent. Anniversary cards will be sent, previous to the meeting, to all entitled to them, and a list of members in good standing will be printed for the opening day. Each of the nine sections will prepare a programme in advance, and notice of papers offered should be sent at an early date to the proper secretary. A special invitation is given to all surviving founders of the Association, that is, of those who shared in the meeting of 1848. The names and addresses of such should be sent at once to Prof. F. W. Putnam, Harvard University, Cambridge, Mass., so that they may enjoy the recognition to which they are entitled.

Cables in War Time.—There appear to be some people who have taken seriously a passing remark recently made by Prof. S. P. Thompson, hence the following letter in the *Pall Mall Gazette*:—

Sir,—In these stirring times of war, it has become more patent than ever how important it is for this country to be in uninterrupted telegraphic communication with its numerous colonies and dependencies. The mere possibility of the cables between Cuba and the outer world being cut naturally suggests what is in store for this country should it unfortunately be at war with a European power. I am surprised that a proposal made by Prof. Silvanus Thompson, in his recent lecture on "Telegraphy Across Space" at the Society of Arts, has not created the attention it deserves, coming, as it does, from so high an authority. The proposal was that if £10,000 were put at his disposal for the purpose, he would be able to erect the necessary apparatus for telegraphing without wires intervening between this country and any part of the globe. To be able to telegraph from London to Cape Town or to Calcutta, or to anywhere you like, without the possibility of the wires being cut, for the simple reason that under Prof. Thompson's plan there would be none to cut, is certainly "a consummation devoutly to be wished." I suggest that Prof. Thompson's plan be further examined, and if he can substantiate his claim—as from his great reputation there should be little doubt—the necessary funds should be put at his disposal by Government, in order to enable him to complete his experiments and to bring to perfection his plan of telegraphing across space.—Anglo-German.

Hedging.—We understand that Mr. Killingworth Hedges, C.E., has been elected a director of the Semzée Greyson Intensified Gas Light Syndicate, Limited.

Royal Institution.—The annual meeting of the members of the Royal Institution of Great Britain was held on Monday afternoon. Sixty-six new members were elected, and 63 lectures and 19 evening discourses were delivered in 1897. The following gentlemen were unanimously elected as officers for the ensuing year:—

President - The Duke of Northumberland, K.G.; Treasurer—Sir James Crichton-Browne; Secretary—Sir Frederick Bramwell, Bart.; Managers—Sir William Crookes, Sir Edward Frankland, The Right Hon. George Joachim Goschen, Donald William Charles Hood, Esq., David Edward Hughes, Esq., Alfred B. Kempe, Esq., Hugh Leonard, Esq., Sir William Huggins, Thomas John Maclagan, Esq., Ludwig Mond, Esq., Alexander Siemens, Esq., The Hon. Sir James Stirling, Sir Henry Thompson, Sir Richard Everard Webster, Sir William Henry White. Visitors—Sir Alexander Richardson Bennie, Sir James Blyth, Bart., Charles Vernon Boys, Esq., Edward Dent, Esq., James Edmunds, Esq., Maures Horner, Esq., Edward Kraftmeier, Esq., Sir Francis Laking, T. Lambert Mears, Esq., Lachlan Mackintosh Rate, Esq., John Callander Ross, Esq., William James Russell, Esq., Sir James Vaughan, James Wimshurst, Esq., Alfred Fernandes Yarrow, Esq.

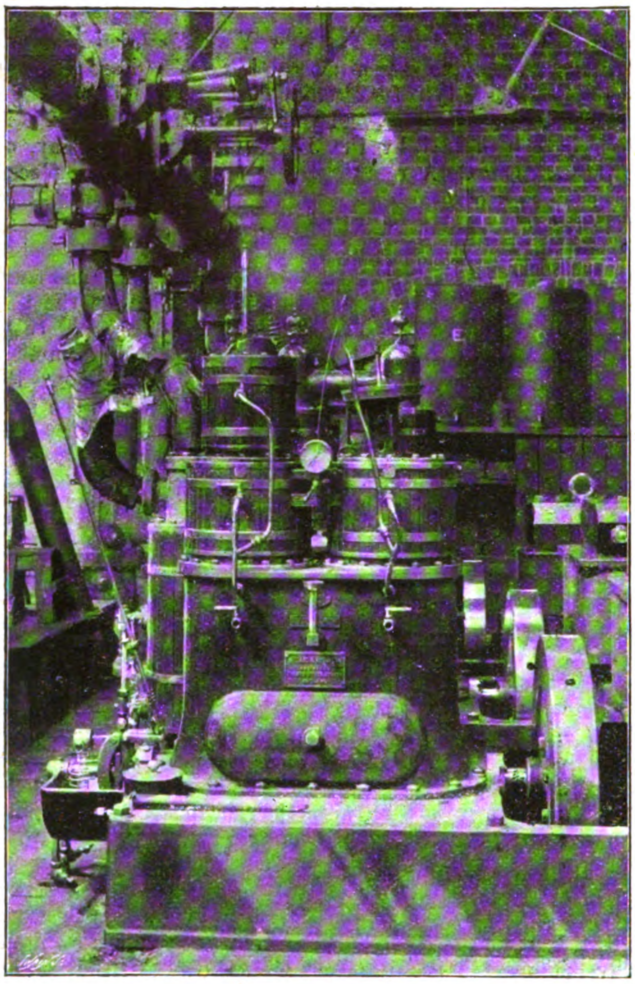
The Jandus Lamp.—The New York *Electrical Engineer* says that a very successful alternating enclosed arc lamp of the non-focusing type for circuits of from 7,000 to 16,000 alternations per minute, and voltages from 100 to 120, is being manufactured by the Jandus Electric Company, of Cleveland, Ohio. A resistance (or economy) coil is placed in the canopy of the lamp, easy of access and conveniently adjusted for the voltage of the arc. The efficiency is high, showing a loss of but 20 watts as the lamp is ordinarily adjusted, *i.e.*, 6 amperes on a 100 to 110-volt line. The lamp ordinarily consumes from 400 to 450 watts across the terminals, thus showing an average efficiency of 95 per cent. The carbons furnished with lamp consist of an equal number of $\frac{1}{2}$ inch core and $\frac{1}{16}$ inch core, each 8 inches long. By using the stub of the upper carbon for a lower in the succeeding run, but one fresh carbon per trim is necessary. One $\frac{1}{2}$ inch core and one solid carbon give good results. The life of one pair of carbons is about 80 hours.

The Welsbach New Gas Burner.—The Welsbach new gas burner has been introduced to the public with the usual blare of trumpets and the inevitable luncheon. At the refection which followed the demonstration at Niagara Hall on Monday, Sir J. Blundell Maple, M.P., gave the company a magnificent advertisement by announcing that his firm had abandoned electric lighting, and had substituted the Welsbach incandescent gas light, because it was cheaper, and produced greater warmth. We should have thought that even the shopkeeping aspect of the question would have had some regard for the truism that cheapness in first cost is not always compatible with economy. That the Welsbach gas light produces, at the expense of the atmosphere, greater warmth than an electric lamp no one will deny, and the Welsbach Company is welcome to the benefit of this argument. We are ourselves not above giving a gratuitous advertisement to the Welsbach Company, and it takes this form: When one is compelled, for one's sins or otherwise, to burn gas, then the Welsbach burner is probably the best in existence. Still, whatever improvements are made in this form of lamp, the great fact still remains that they burn the same old gas.

The Trolley in America.—From the *Electrical World* we learn that by a recent final decision given by the United States Circuit Court of Appeals in an action of the Thomson-Houston Electric Company *v.* the Union Railway Company, henceforth anyone can make or use the overhead trolley in America without paying royalties. The case referred to involved two claims of the Van Depoele Patent No. 450,443, over which there has been almost continuous litigation for several years. Although, according to our contemporary, the decision is merely on a motion for preliminary injunction to prevent the Union Railway Company from using the overhead trolley while the main case is awaiting decision, this opinion, being based on a point of law, applies to the main case, and renders the use of the trolley free from any fundamental patent claims, although there are, of course, plenty of details of construction still covered.

The War and the Malaga Electricity Works.—The chairman of the Malaga Electricity Company, Mr. R. C. Wyatt, of Moorgate Street, E.C., has been in communication with the Foreign Secretary, stating that this and another English company in Spain are in urgent need of coal, and if a supply cannot be obtained at once they must stop work, in which case the action of the idle Spanish workmen might be disastrous. The Foreign Secretary in his reply regrets that he cannot advise the companies in regard to their request for permission to charter two steamers from England to carry coal for the purpose of these works.

Mishap at Southampton Electricity Works.—On Thursday evening last week an accident occurred in the engine room at the Corporation Electricity Works at Southampton. The top of a G.G.S. Willans engine blew off, the cause being either water or something such as a broken ring or



pin getting into one of the steam ports. The damage is practically confined to the engine itself. The supply was maintained by the engines which were running in the new engine room. Very fortunately no one was injured. The photographic illustration will give some idea of the damage.

Appointments Vacant.—The Redditch District Council wants an engineer for the electricity works. See our "Official Notices" this week for particulars.

The Poplar Board of Works wants a resident electrical engineer to devise and carry out an electric lighting scheme. See our "Official Notices" to-day for particulars.

The Institution of Civil Engineers.—The Council have made the following awards for papers read and discussed before the Institution during the past session:—A Telford medal and premium to Mr. A. H. Preece, and a Telford premium to Mr. L. B. Atkinson. The presentation of these awards will take place at the inaugural meeting of next session.

The Telelectroscope.—Although we are not much impressed with the invention of the gentleman whose name wants ironing out, Herr Jan Szczepanik, we believe it is, there seems to be sufficient evidence that his suggested arrangement of oscillating mirrors has been anticipated by Messrs. Bastian & Parsons, who carried out experiments seven years ago. We have seen the correspondence and drawings referred to by these gentlemen in their letter, and, without going into the matter very closely, there seems to be *à priori* publication of Herr Szczepanik's idea of employing vibrating mirrors.

Holophane Globes.—The Committee on Science and the Arts of the Franklin Institute is reported to have recommended the award of the John Scott Legacy Medal and premium to Messrs. Blondel and Psaroudaki for their invention of holophane globes.

Falcon Works Engineering Society.—The annual dinner of the Falcon Works Engineering Society was held at Loughborough on Friday last. Mr. J. S. Raworth presided, and there were some 56 other guests present, including a large proportion of old members of the Society.

NEW COMPANIES REGISTERED.

Electric Laundry Company, Limited (57,077).—Registered April 22nd, with capital £10,000 in £1 shares, to carry on at Hampstead and elsewhere in the counties of London, Middlesex, Hertford, Surrey, Kent and Essex, the business of a laundry, as the same has been carried on by A. W. Armstrong, and to adopt a certain agreement. The subscribers (with one share each) are:—F. M. Marden, 3, Welbourne Road, Tottenham, clerk; F. Dawson, 41, Bookham Street, Hoxton, clerk; T. Dunsdon, 53, Shrubland Road, Walthamstow, clerk; W. T. Edmunds, 118, Beckenham Road, Beckenham, clerk; W. J. Hanbury, Iseldene, Beddington Corner, Mitcham, clerk; H. Elliott, 32, Chichester Road, Leytonstone, clerk; B. Templeman, 10, Haxlitt Road, Kensington, clerk. Table "A" mainly applies. Registered office, 16, Rosemont Road, Hampstead.

Electric Railway and Tramway Carriage Works, Limited (57,082).—Registered April 25th, with capital £150,000 in £5 shares, to acquire "The North of England Railway Carriage and Iron Works," West Strand Road, Preston, and to adopt a certain agreement and to carry on the business of tramway car builders, tramway, railway, omnibus and van proprietors, carriers, electricians, electrical and mechanical engineers, suppliers of electricity, machinists, &c. The subscribers (with one share each) are:—J. Kerr, 94, George Street, Edinburgh, contractor; G. Flett, 110, Cannon Street, E.C., contractor; B. Sykes, 33, Winckley Square, Preston, civil engineer; T. S. Turnbull, The Woodlands, St. Anne's-on-Sea, solicitor; A. H. Mayne, 13, Spring Gardens, Manchester, solicitor; F. Cox, Ruthven House, Marple, Cheshire, accountant; F. Crimes, 5, Merimer Street, Greenheys, Manchester, clerk. The number of directors is not to be less than four nor more than seven. The first are G. Flett, G. F. Fry, J. Kerr, R. H. Prestwick, and G. Richardson. Qualification, £500; remuneration, £600 per annum and a share in the profits divisible. Registered office, 13, Spring Gardens, Manchester.

British Continental Electricity Company, Limited (57,088).—Registered April 26th, with capital £20,000 in £10 shares (1,000 5½ per cent. cumulative preference), to carry on the business of electricians, mechanical, hydraulic, and general engineers, suppliers of electricity, electrical apparatus manufacturers, &c. The subscribers (with one share each) are:—W. A. Brodie, Villa Olivetti, Bordighera, electrical engineer; W. R. Cooper, 87, Upper Tulse Hill, S.W., electrical engineer; R. Alioth, 10, Albanalage, Basle, electrical engineer; C. J. Brodie, Fern Hill, Wootton, Isle of Wight, surgeon; F. C. Brodie, Sandown, Isle of Wight, physician; Mrs. S. C. Brodie, Sandown, Isle of Wight; S. Ward, 35, Gracechurch Street, E.C., solicitor. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first; qualification £1,000; remuneration not exceeding 20 guineas each per annum. Registered by Ward & Co., 85, Gracechurch Street, E.C.

Davey Paxman & Co., Limited (57,093).—Registered April 26th, with capital £250,000 in £10 shares, to adopt an agreement with J. N. and W. Paxman, for the acquisition of the business carried on as "Davey Paxman & Co.," at Colchester and elsewhere, and to carry on the business of mechanical electrical mining, water supply and general engineers, agricultural implement and tool makers, boiler makers, rolling stock and waggon builders, &c. The subscribers (with one share each) are:—J. N. Paxman, Colchester, engineer; W. Paxman, Colchester, engineer; A. P. Butcher, Colchester, manager; H. G. Plane, Colchester, manager; W. H. King, Colchester, secretary; J. J. Phillips, Colchester, foreman; T. W. Hall, Colchester, draughtsman. The number of directors is not to be less than two nor more than five; the first are J. N. Paxman (chairman), W. Paxman, and W. Marriage; qualification, £250; remuneration as the company may decide. Registered by Robinson and Stannard, 19, Eastcheap, E.C.

Macartney, McElroy & Co., Limited (57,101).—Registered April 26th, with capital £12,000 in £10 shares, to carry on the business of electrical engineers and contractors, consulting electrical engineers, and undertakers for the construction, supply and sale of electric plant, and to adopt an agreement with J. F. Macartney, J. A. McElroy, and B. W. Champion. The subscribers are:—J. F. Macartney, 41, Edgware Road, W., contractor, 90 shares; J. A. McElroy, 26, Cortland Street, New York, U.S.A., mechanical engineer, 90 shares; B. W. Champion, Queen's College, Cambridge, gentleman, 100 shares; H. J. Dawson, 15, Emmanuel Road, Cambridge, gentleman, one share; L. Cobbett, M.B., 2, Round Church Street, Cambridge, one share; W. R. Scott, 100, Great Western Road, Glasgow, engineer, one share; J. Speak, Kirton Grange, near Boston, England, gentleman, one share. The number of directors is not to be less than three nor more than seven; the first are the first three subscribers; qualification, £500. Registered by C. F. Martelli, 10, Staple Inn, E.C.

Electricity, Limited (57,121).—Registered April 27th, with capital £51,000 in £1 shares (1,000 founders'), to adopt an agreement with C. O'D. Barrow and C. H. Smith, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers are:—P. W. Davis, 61½, Fore Street, E.C., merchant, 250 shares; G. W. Grabham, M.D., Mathyns, Witham, Essex, 250 shares; C. G. Smith, 59, Hatton Garden, E.C., manager, one share; A. I. Grabham, 59, Farrington Road, S.E., engineer, one share; T. J. Stockall, 6, Clerkenwell Road, E.C., merchant, 250 shares; J. J. Stockall, 50, Ferme Park Road, N., merchant, 250 shares; H. Verden, 14, Great Winchester Street, E.C., solicitor, one share. The number of directors is not to be less than three nor more than seven. The first are the first five subscribers. Qualification, £250; remuneration, £200 each per annum (£300 for the chairman) and a percentage of the profits. Registered office, 6A, Austin Friars, E.C.

Frank Suter & Co., Limited (57,193).—Registered May 2nd, with capital £20,000 in £1 shares (4,000 5 per cent. cumulative preference), to adopt an agreement with F. W. Suter, H. E. H. Wyman, and T. White, and to carry on the business of electricians, electrical engineers, workers and dealers in electricity, motive power and light, founders, tool makers, boiler makers, millwrights, &c. The subscribers (with one share each) are:—F. W. Suter, 66, Berners Street, W., electrical engineer; H. E. H. Wyman, 66, Berners Street, W., electrical engineer; T. White, 66, Berners Street, W., electrical engineer; F. H. Jerson, 44, Downshire Hill, Hampstead, secretary; A. M. Bramall, 23, Leadenhall Street, E.C., solicitor; P. Holmes, Brookfield Cottage, Chigwell, Member Stock Exchange; G. S. Saunders, 23, Leadenhall Street, E.C., solicitor. The number of directors is not to be less than three nor more than five; the first are the first three subscribers; qualification £500. Registered by Bramall and Co., 23, Leadenhall Street, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Notting Hill Electric Lighting Company, Limited (25,921).—This company's return was filed on April 5th, when the whole capital of £100,000 in £10 shares (6,452 ordinary, 550 founders', and 2,998 ordinary preference) was taken up. The full amount has been called, and £100,000 has been paid.

Kensington and Knightsbridge Electric Lighting Company, Limited (26,193).—This company's return was filed on March 24th. The capital is £350,000 in £5 shares (50,000 ordinary, 10,000 first preference and 10,000 second preference); 15,000 ordinary, all the first preference, and 5,500 second preference have been taken up, and 5,000 ordinary are considered as paid; £5 per share has been called on the others, and £127,500 has been paid.

Rugby School Electric Lighting Company, Limited (39,309).—This company's annual return was filed on April 18th, when 90 shares were taken up out of a capital of £5,500 in £50 shares, and paid for in full.

Hove Electric Lighting Company, Limited (36,942).—This company's return was filed on March 29th, when the whole capital of £40,000 in £5 shares was taken up; £5 per share has been called and £39,970 has been paid, leaving £30 in arrears.

CITY NOTES.

Kingston-on-Thames Accounts. WE have not previously had an opportunity of referring to the very marked progress that was made by the Municipal Electricity Works at Kingston during the year 1897.

Mr. J. E. Edgcome, the borough electrical engineer, in his report to the Corporation points out that after the payment of all the works' costs for generation of electricity, maintenance and repair of machinery and mains, taxes, insurance, and all management expenses, there remains a balance of £867 19s. 9d. as compared to £301 3s. 1d. for 1896. This sum is sufficient to pay the interest for the year on the capital expended on the undertaking, leaving a balance of £43 12s. 1d. towards the repayment of principal. In other words, if the undertaking were the property of a company, sufficient profit on the works had been made during 1897 to pay interest at the rate of 3½ per cent., and to leave a sum of £43 12s. 1d. in hand to be carried to the reserve fund.

We note that very considerable extensions are in hand, and if the present rate of progress is maintained, there is little reason why the close of the present year should not see the works approaching the profit-earning stage. The cost of production has been largely diminished, as will be observed from the subjoined figures.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£36,700*	—
Number of units sold	194,268	155,681
Number of lamps connected	9,200	6,825
Revenue from sale of current	£3,765	£2,892
Net revenue	£868	£301
Average price obtained per unit	4·85d.	4·64d.

Cost of production.	£		Per unit.	1896.
Coal	1,314		1·62d.	1·79d.
Oil, waste, water, and engine room stores	155		·19d.	·22d.
Salaries and wages at generating station	625		·77d.	·93d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	364	Works' cost 3·03d.	·45d.	·60d.
Rent, rates and taxes	100		·12d.	·12d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	454		·56d.	·58d.
Depreciation of buildings and plant account	-		—	—
Renewal fund account	—		—	—
Total	£3,012		3·71d.	4·24d.

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	3,765	0	0	4·85d.
Meter rents, &c.	104	0	0	—
Supply of steam	—			—
Transfer fees	—			—
Sundry sales	60	0	0	—
Total	£3,929	0	0	4·85d.

* Includes extensions now in hand.

Total cost per unit (exclusive of depreciation and renewal accounts), 3·71d.; works' cost, 3·03d.

Elmore's German and Austro-Hungarian Metal Company.

THE report of the directors of Elmore's German and Austro-Hungarian Metal Company, Limited, for the year 1897, to be submitted to the general meeting to be held in London on May 11th, states that the reduction of capital authorised by the meeting of July 21st last has been duly carried out, and that after writing off the amount brought forward, and the charges for the year, the amount standing to the cost of patents has been reduced to £84,252. The preference shares issued have been increased by the issue of £10,000 in July last. It will be remembered that this issue was made at the request of the meeting called for the reduction of capital. The loan to the "Metall" Company has been increased to £39,045, and mortgages to the extent of £40,000 upon the property at Schladern have been lodged with the trustees for the debenture holders. The option given to a syndicate in Hungary for the purchase of a license expired, and the directors did not see their way to renew it. They are now negotiating with one of the most important firms in Hungary, upon terms similar to those asked for last year, and, they believe, with a fair prospect of success. The debenture stock of the company, which now stands at £44,983, falls due for redemption on July 1st next. It is proposed to take power to issue £75,000 of debenture stock at 6 per cent., and to issue £60,000 during the present year, out of which the 8 per cent. stock will be repaid, and the balance expended in the purchase of copper, &c., at Schladern. With regard to the "Metall" Company's accounts, the directors, while regarding a profit of £3,203 as satisfactory, cannot but admit that the amount does not come up to their expectations. The value of the sales was 50 per cent. more than those of 1896, while the trading profit was £333 less. The decrease in the profit was due to the Government ordering a very much larger quantity than the directors were informed they would of tubes at the base, or lowest price. The directors demurred to this, and as a new regulation came into force, which gave the company power to cancel the contract, it was arranged that it should be cancelled. This was done, and, at the request of the Admiralty, the company tendered again, but at greatly enhanced prices. The directors are glad to report that the tender has been accepted, and that the company has been allotted nearly the whole of the new contract, only small tubes up to 1⅝ inches in diameter going elsewhere. Notwithstanding the increase in the sales during the past year, the company were unable to accept even a moiety of the orders offered, and therefore gave orders for new plant, sufficient to double the output of the year 1897. A portion of this new plant is already at work. The sales for the quarter ended March 31st show an increase of 77 per cent. over those for the same period last year. The directors have also purchased additional land available for further extensions, upon a portion of which they have erected workmen's dwellings. The directors are pleased to report that the process now works smoothly, and that the new plant being erected contains improvements which reduce materially the cost of repairs and maintenance. With regard to the profit shown, the directors would beg to remind the shareholders that the sum of £5,749 has been deducted from revenue by way of depreciation during the past three years. In view of the cash requirements of the "Metall" Company for the new plant and copper at Schladern, the directors regret they cannot recommend the payment of a dividend out of the profit, and have carried forward the amount to the credit of the accounts for this year.

Calcutta Electric Supply Corporation, Limited.

The first annual general meeting was held on Friday last, at Cannon Street Hotel, Colonel A. J. Filgate presiding.

In moving the adoption of the report, the Chairman regretted that greater progress had not been made with the works of the company, but they had had many matters to deal with which had occasioned delay. The question of what mains should be laid underground and what wires fixed overhead had involved protracted negotiations with the Government of Bengal, the Telegraph Department, and the municipality of Calcutta, but in February last the Government engineer approved a scheme which enabled the directors to give the necessary orders to the contractors to carry out the works. According to a telegram received a day or two ago, the Government authorities and the Calcutta municipality had agreed that, on the expiration of the period of 21 years for which the company's concession had been granted, it should be renewed for a further like period unless the undertaking was purchased by the municipality. On the whole, he thought the affairs of the company were now in a satisfactory state, and that the whole of the mains at present contemplated would be ready by the time the generating station was in a position to supply current. From what he knew of Calcutta, he believed they were likely to have a very successful undertaking.

Mr. E. Boulnois, M.P., seconded the motion, which was adopted.

City of Birmingham Tramways Company, Limited.

Mr. James Ross presided at the annual meeting of the company, held at Birmingham last Friday, and pointed out that the financial results had been satisfactory, in spite of the fact that their endeavours to improve the system had been frustrated by the Committee of Public Works and the Council. The chairman then detailed the circumstances, and quoted from letters to show that the Council had accepted the terms of the company to construct an overhead wire system with not more than 10 miles of conduit. Subsequently the Council withdrew their consent to permit an overhead system to be erected. The chairman, in conclusion, mentioned that the board had appointed as managing director Mr. G. C. Cuningham, who had had considerable tramway experience in Canada. Under the extended powers arranged between the Council and the company some time ago a new system was to be installed, and the public were looking for splendid concessions, but all this had been put on one side by a sudden and unexpected change of front on the part of the Public Works Committee.

The report was then adopted, and a dividend at the rate of 5 per cent. declared on the ordinary shares.

The Eastern Extension, Australasia, and China Telegraph Company, Limited.

The gross receipts for the half-year ended December 31st, 1897, including Government subsidies, amounted to £275,142 7s. 2d., against £325,405 12s. 6d. for the corresponding period of 1896. This decrease is due to the reductions of tariff brought into force during the past year and the falling off of Australasian traffic. The working and other expenses, including £30,956 8s. 6d. for cost of repairs to cables and expenses of ships, absorb £102,844 13s. 10d., against £106,270 9s. 7d. for the corresponding period of 1896, leaving a balance of £172,297 13s. 4d. From this is deducted £4,559 2s for income-tax, £32,606 13s. 9d. for interest on debentures, debenture stock, and contribution to sinking fund, &c., leaving as the net profit for the half-year £135,131 17s. 7d., which, with £34,812 16s. 3d. brought forward from the previous half-year, shows an available balance of £169,944 13s. 10d. One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on the 12th prox., making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1897. The balance of £57,444 13s. 10d. has been transferred to the general reserve fund. The report states:—"The policy of strengthening the service by making judicious renewals from time to time in the weakest sections of the cables has been continued during the half-year under review, and the cost of the renewals carried out during that period has been charged against the general reserve fund. The contract made with the Spanish Government for extending the company's system from Manila to the islands of Panay, Negros and Cebu was successfully completed, and the new cables opened for traffic in November last. Since the close of the half-year a further contract has been entered into with the Spanish Government for improving telegraphic communication with the Philippines by extending the Hong Kong cable, which was originally landed at Cape Bolinao (Luzon), direct to Manila. The contract was completed last month, and the station at Bolinao removed to Manila. In accordance with the provisions of the trust deed dated May 10th, 1879, 451 of the company's 5 per cent. Australian Government subsidy debentures, amounting to £45,100, were drawn by lot on the 4th inst., for payment at par on July 1st."

The West Coast of America Telegraph Company, Limited.

The report of the directors for the year ended December 31st, 1897, to be presented at the first ordinary general meeting on May 10th, 1898, states that the gross income for the year 1897, as shown in the annexed revenue account, was £25,773. The continued depressed state of the nitrate industry, and of trade generally on the West Coast of South America, has had an adverse effect upon the traffic receipts; but the income of the company was sufficient to provide for the working expenses (£19,476 0s. 2d.) and the interest on the 4 per cent. debentures, leaving a balance of £296 19s. 10d. to be carried forward. The company's cables, landlines, and the repairing steamer have been maintained in a state of efficiency. The directors regret to report the decease of their esteemed colleague, Lord Sackville A. Cecil, on January 29th last, to replace whom, Sir Albert J. Leppoc Cappel, K.C.I.E., has been elected by the board.

The Spiral Globe, Limited.

As foreshadowed in our last issue, the prospectus of this company is now before the public, the capital offered being 75,000 shares of £1 each, out of a total capital of £150,000.

The vendor, Mr. S. B. Apostoloff, of 5, Fenchurch Street, London, has fixed the price at which he is willing to sell the whole of the patents and patent rights to the company, at £10,000 cash, £25,000 in fully paid shares, and £30,000 in cash or shares at the option of the directors. The company has in addition to pay a further sum of £25,000 in cash to the vendor on the sale or commercial working of the various foreign patents if as and when sold, a certain sum being allocated to each patent.

The spiral globe is a simple and pretty addition to an ordinary incandescent lamp, and apparently acts as a collector and diffuser of the light rays. It has, however, the disadvantages of acting as a dust collector, and of being fragile. Mr. F. J. Down estimates the sales at the rate of 2,000,000 per annum, and the profits on these sales at £26,000 per annum, increasing with a natural increase of sales to £35,000 per annum in subsequent years. We cannot follow this enthusiast in his appreciation of the invention, as shown by his report, but we think the spiral globe a pretty addition to the lamps ordinarily sold, and were the vendor content with pence, instead of the pounds named, there might be some future for the company.

London Platino-Brazilian Telegraph Company, Limited.—A meeting of this company was held at the offices of the company at London Wall yesterday, but we were informed that the proceedings were private.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending April 29th, 1898, were £2,694 4s. 7d.; corresponding period 1897, £2,292 0s. 3d.; decrease, £402 4s. 4d.

The City and South London Railway Company.—The receipts for the week ending May 1st, 1898, were £988; week ending May 2nd, 1897, £934; increase, £54; total receipts for half-year, 1898, £18,757; corresponding period, 1897, £18,546; increase, £211.

The Dover Corporation Electric Tramways.—The receipts for the week ending April 30th, 1898, £130 8s. 10d.; total receipts to April 30th, 1898, £1,951 11s.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, April 29th, 1898, were £476 15s. 8d; corresponding week last year, £537 18s. 7d.: decrease, £61 2s. 11d.; passengers carried, 77,851: corresponding week last year, 81,812; aggregate to date, £7,3[illegible] 17s. 1d; aggregate to date last year, £7,655 3s. 10d.; decrease to date, £286 6s. 9d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending May 1st, 1898, amounted to £1,451; corresponding week last year, £1,276; increase, £175.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending May 2nd, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,362.

THE STEAM TURBINE ENGINE AND ITS APPLICATIONS.*

By JNO. D. BAILIE.

During the 13 or 14 years which have elapsed since the introduction of the compound steam turbine, many modifications and changes have been made both in the engine itself and in its auxiliary parts. A *résumé* of the various forms through which this engine has passed would occupy more time than is at disposal; it may, however, be said that the two most prominent types—judging from the standpoint of practical and commercial success—have been the "Twin Parallel Flow" and the "Radial Flow" turbines, and as many of both of these are still at work in central electricity supply stations and elsewhere, it may be well to begin the paper by a brief description of their leading features.

In the twin parallel flow turbine the motor spindle is fitted with two sets of rings of curved blades, one complete set in each half of the machine, and on the inner periphery of the cylinder are corresponding rings of blades of opposite curvature between which those on the spindle rotate. The blades on the inside of the cylinder are guides, their function being to direct the steam on to those on the spindle. Steam is admitted at the centre of the turbine case, all round the shaft, and flows simultaneously right and left through each series of rings of blades to the ends of the cylinder, thence to the common exhaust—the rotation being caused by the impact of the steam on the spindle blades. The flow of steam being equal in each direction, end pressure and excessive wear on the bearing collars are avoided.

The bearings are of somewhat unusual construction. Surrounding the bearing sleeve, or bush, are two sets of steel washers, which are in turn encircled by a steel liner—the latter being a free fit in the bearing seat. Each washer is about $\frac{1}{16}$th inch thick. They are of two diameters, and are arranged alternately small and large, the smaller being a close fit on the bush and about $\frac{1}{32}$nd inch clear of the liner, and the larger a close fit in the liner and about $\frac{1}{32}$nd inch clear of the bush. They are held tightly together by a strong spiral spring, and any lateral movement due to imperfect balance makes them slide mutually against one another, thus permitting the shaft to find its own centre of gyration, relieving the pressure on the bearings, and damping vibration.

The lubrication of the bearings is automatic and continuous by means of a fan and a screw fixed on the turbine shaft. The suction of the fan acting on the free surface of the oil in the stand-pipe draws it up to the screw, which in turn forces it through the adjacent bearing, and also through a feed-pipe to the other bearings, from whence it flows back through a return pipe to a reservior, to be again raised by the fan, and the process repeated.

The speed is controlled by a rather nice arrangement. A leather diaphragm is mechanically connected to the throttle valve by means of a rod and crank, and so operates it, that as the diaphragm distends the throttle valve opens to steam, and *vice versâ*. An airway leads from the diaphragm to the inlet of the fan, so that when the turbine is working, the suction of the fan tends to close the diaphragm against the tension of a spring. The action is as follows:—When the speed becomes too high, the suction of the fan increases, partially closes the diaphragm, and so reduces the admission of steam; conversely, when the speed falls below the normal, the suction of the fan decreases, the diaphragm extends, and opens the throttle valve to admit more steam. This combination in itself exerts very fair control, but is scarcely sensitive enough for electrical work; it is therefore supplemented by an electrical regulator. On the magnet yoke is a vertical spindle, on which are delicately pivoted a small iron bar or needle, and a tuning fork shaped arrangement with flat heels. An air-pipe leads thence to the leathern diaphragm. When the machine is excited, the magnet yoke attracts the needle, and a spiral spring makes it tend to resist the attraction. The spring is so adjusted, that the greater the magnetic pull, the more is the mouth of the air-pipe closed by the hind heel of the tuning fork. When, therefore, the speed of the machine, and consequently the magnetic pull, get below the normal, the heel falls back and opens up the mouth of the air-pipe, the inrush of air tends to neutralise the suction of the fan, and allows the diaphragm to extend, thus opening the throttle valve to admit more steam. On the other hand, when the speed and magnetic attraction get above the normal, the heel closes the air-pipe inlet, allows the fan to contract the diaphragm, and so reduces the admission of steam.

The radial flow turbine differs from the foregoing in that, instead

* Abstract of a paper read before the Yorkshire College Engineering Society, February 14th, 1898.

of the steam flowing in a direction parallel to the axis, it flows radially outwards. In this type there are several discs fixed on the shaft, and revolving with it, from the front faces of which the blades or vanes project in the form of a series of concentric rings. In one complete turbine motor there would be, perhaps, six of these discs of equal diameters, also a disc of considerably greater diameter fitted on both its faces with rings of blades of larger dimensions than those on the other discs; this large one may be termed the low pressure disc. Between the moving discs are stationary discs, attached to the case, on which the rings of guide vanes are so arranged as to alternate with the rings of moving blades. Steam enters at one end of the cylinder, inside the smallest ring of blades on the first disc, passes through the successive rings to the circumference, thence between the back of the rotating disc, and of the next stationary disc, to the inmost of the next series of rings. This is repeated until the centre of the low pressure disc is reached, when the steam flows through the blades on both sides of the disc simultaneously, and thence to the exhaust.

The steam turbine as now made is somewhat similar to the one first described, in that it is of the parallel or axial flow type.

The turbine shaft is encircled concentrically by a series of "drums" of several diameters, round the outer circumference of which the sets of rings of moving or rotator blades are fitted. The interior of the turbine case is correspondingly stepped, and is fitted with rings of guide blades of similar but opposite obliquity to those on the spindle. The rings of guide blades alternate with the rings of rotator blades, so that when the machine is at rest the spaces between the blades form a series of zig-zag passages or channels. The diameters of the drums, the dimensions of the blades, and the steam passages, are graduated to suit the increase in the volume of the steam as it expands towards the low pressure end. Each ring of guide blades, together with its corresponding ring of rotator blades, may be regarded as a turbine complete in itself, the steam turbine engine therefore consists of a considerable number of small turbines, at each of which expansion of the steam takes place. Steam is admitted through a double-beat valve, and entering the cylinder all round the spindle, passes through the first ring of guide blades on to the first ring of rotator blades, then through the second ring of guide blades to the second ring of rotator blades—and so on, losing pressure at each step, until it has passed the last ring of rotator blades, when it exhausts into the condenser or atmosphere, as the case may be.

No effective work is done by the barrels; they are merely revolving baffle pistons, or "dummies," to balance the end thrust due to the pressure of the steam on the turbine blades. They are stepped similarly to the bladed barrels, with which those of corresponding diameters are connected by channels in the casting in order to equalise the pressure. The adjustable thrust bearing takes up any slight endlong pressure which may not be neutralised by the dummies. This thrust bearing differs from the usual pattern only in that the grooved bush is split longitudinally into halves, with separate adjustment for taking up wear. The thrust bearing is adjusted by a screw at the end keep of the engine. The end play can be tried when the engine is running slow by slackening the nuts holding down the keep, and inserting a lever between the keep and the cylinder; it should not be more than, say, $\frac{1}{100}$th inch. If the bottom half of the thrust is worn, a thin liner may be put in at the back.

The bearings are of the tubular type, and consist of a phosphor bronze, or gun-metal bush in which the shaft rotates; round this bush are slipped three concentric steel tubes, each fitting loosely over the one inside it, the outermost being a free fit in the bearing seat. The bush has grooves cut on its inner periphery, and the tubes are perforated to allow the free passage of the oil. When the machine is working the clearance between each tube and its neighbour is charged with a film of oil, with a result that, while the shaft retains a small amount of freedom, the viscosity of the oil acts as a damper to prevent oscillation. The circulation of the oil is continuous and automatic by means of a pump driven by an eccentric and worm gear from the turbine shaft, the supply of oil is therefore proportionate to the speed. In some machines the oil is continuously fed into the bearings under a head of some 6 or 8 inches, from cisterns immediately above them; it then drains into a receiving chamber, from which it is again pumped to the various cisterns. In other machines the keeps are sealed, and the oil is forced through the bearings under a pressure of from 5 to 10 lbs. per square inch. The cisterns are all connected by pipes, so that the one pump maintains the circulation.

When the turbines are to be used in tropical climates, or in exceptionally hot places, oil coolers are frequently fitted. These may be built into the bed-plates, and consist merely of a cast-iron shell containing a spiral copper tube, through which the oil is passed on its way to the reservoir, the cooling being effected by a water circulation.

The engine is coupled to the fan, dynamo, pump, or other machine to be driven, by means of a square bored sliding sleeve, fitting loosely over the squared ends of the respective shafts. The exterior of this sleeve carries the worm which drives the worm-wheel, which in turn, by means of an eccentric and connecting rod, transmits the motion to the oil-pump plunger.

This worm gear also plays an important part in the governing arrangements; but as the method adopted for controlling the turbine depends upon the nature of its work, it will be dealt with later on.

When very large powers are required, it is sometimes found advantageous to use more than one cylinder, and to pass the steam through them in the usual sequence.

Turbines are designed for working either condensing or high pressure, and they lend themselves readily to either condition. At some places they are required to work part of the time on the condenser, and part on the atmosphere; when this is so, they are bladed for condensing, but fitted with a bye-pass and valve, with which the excess blades may be cut out when working on the atmosphere. The relative saving effected by condensing is more than with reciprocating engines, for the steam may be expanded down to 1 lb. absolute, or even lower, without any material increase of frictional resistance, and a very high ratio of expansion is therefore practicable; indeed, it is usual to blade a condensing turbine for the terminal pressure of 1½ lb. absolute per square inch. It is evident, therefore, that where condensing is feasible it should be resorted to, and the condenser adopted should be one giving a high vacuum. Frequently the engine is fitted with its own condenser; the shell containing the tubes forming part of the bed-plate, and the air and circulating pumps being driven from the worm on the turbine shaft by a rocking beam.

The turbine is best adapted for speeds of not less than 2,000 revolutions per minute, and they are usually designed to run at from 3,000 to 6,000 revolutions; when the speed of the machine to be driven is considerably below 2,000, gearing or belts may be interposed. At first sight, gearing would seem to be unsuitable for these speeds, both as regards durability, efficiency, and quietness of running, but very fair results have been obtained with double helical spur gear made of steel. This type of gear is also used when it is desired to adjust relatively higher speeds, and ratios of as high as 8 to 1 have been successfully negotiated. In a 16-kilowatt turbo-dynamo built some time ago, the turbine ran at 25,000 revolutions, and the dynamo at 4,000 revolutions, a ratio of 6¼ to 1. A 150-kilowatt turbo-alternator at the Newcastle and District Company's station has a ratio of 2 to 1, the turbine running at 9,400 revolutions and the alternator at 4,700 revolutions. Hitherto, reducing gear has not been employed when the machines have been built for power work, but at the present time a launch is being engined with a turbine gearing on to two propeller shafts. The use of reducing gear enables the turbines to be run at a very high speed, and so greatly decreases the weight per horse-power, but at present the writer much prefers direct driving, especially when the load is liable to sudden variation.

The Steam Turbo-Dynamo.

When the turbine engine was first introduced, electrical engineers recognised its marked suitability for driving dynamos, and for several years this was the only use to which it was put. The first turbo-dynamo built was a small one, giving only 4½ kilowatts, and running at 18,000 revolutions per minute; nowadays, for central electricity supply stations, plants having capacities of from 350 to 1,000 kilowatts are not uncommon. One of the large London companies alone has no fewer than 13 of these turbine plants, each giving 350 kilowatts, four each giving 500 kilowatts, and others equally large are being built for them at the present time. They are also used in the supply stations of Newcastle, Cambridge, Woking, Portsmouth, Scarborough, Madeira, Woolwich, Blackpool, &c., so that their fitness for this class of work would seem to be proved.

Turbo-dynamos are also being largely and increasingly used for power work at collieries, for driving iron works and other places where heavy and sudden changes of load are met with, as well as for electric traction, and they do their work well. Indeed, this is a direction in which, in the opinion of the writer—and in the opinions of the users also—they score heavily over reciprocating engines. He would emphasise this by adding that, so far as he is aware, in no single instance where users have installed turbines for power work have they, when extending, reverted to reciprocating plant. The principle of the engine eminently fits it for dealing with extremely variable loads without detriment, and the governor, which being a special feature will be described at length later on, exercises such perfect control that practically no attention is required.

The steam turbine dynamo ordinarily comprises a multiple expansion steam turbine coupled direct on the same bed-plate to a high speed dynamo, by means of a square bored sleeve. The dynamo bearings are similar to those of the engine, and are connected with them by pipes, so that the one oil pump provides the circulation for all.

The electrical governor which controls the speed of the machine is very quick and reliable in its action.

A centrifugal "safety" governor is usually fitted to large machines, to come into action only in the event of accident. It derives its motion from the worm on the turbine shaft through the worm wheel and the bevel gear, and actuates a valve in the relay by means of a rod and clutch. It is set so as just not to blow off when the machine is at full speed.

The hand lever above the relay is merely for the purpose of lifting the main valve at starting, or for admitting steam to warm through. A similar lever embraces the collar of the centrifugal governor spindle. Either of these levers might be used in an emergency for shutting off steam from the engine; the long lever will answer the same purpose, for if moved either to its top or bottom position, the main valve closes.

Turbo-alternators run perfectly in parallel, either with each other or with any of the leading slow speed machines.

These turbo-electric generators would seem to compare very favourably with other types as regards economy in steam consumption, especially when working condensing. A 100-kilowatt turbo-dynamo supplied to one of the Lancashire corporations gave a consumption of 20·1 lbs. of steam per electrical horse-power at full load, and 22·3 lbs. at half load. The steam pressure at the machine was ·02 lbs., and the and the vacuum was 26¾ inches. A 50-kilowatt plant, supplied to the same corporation, used 20·9 lbs. per electrical horse-power at full load, the steam pressure being 90 lbs. and the vacuum 28½ inches.

A 200-kilowatt plant supplied to a large ironworks near Chester gave, with a boiler pressure of 100 lbs. per square inch and a vacuum of 25 inches, a consumption of 19·51 lbs. per electrical horse-power at full load, and 20·9 lbs. at half load, a rise from full load to half load of only 7½ per cent.

A 150-kilowatt turbo-alternator supplied to a central electricity supply company gave the following results:—The steam pressure at the machine was 70 lbs. per square inch, and the vacuum was 26½ to

26¾ inches; the steam consumption at full load was 17·28 lbs. per electrical horse-power, at half load 20 lbs., and at one-fourth load 22·01 lbs.

In all the above, the consumptions are to be taken as per electrical horse-power-hour.

The machines quoted are not necessarily the most efficient that have been built; the writer has chosen them because he has been connected with them to some extent, three out of the four having passed through his hands; he thinks, therefore, that they may be taken as fair examples of the efficiency of condensing type steam turbine plants of medium size.

The writer concludes by saying that the advantages claimed for the turbine are:—Simplicity, compactness, lightness, portability, absence of vibration, low cost of foundations, ease and cheapness of repairs, long life of bearings, automatic lubrication, steady governing, absence of cylinder lubrication, economy in oil, indifference to priming, low all round steam consumption, absence of cylinder condensation, general satisfactory working, and saving in attendance.

COMMERCIAL FORMS OF ELECTRICAL RESISTANCES FOR LIGHTING AND POWER PURPOSES.*

By Ll. B. ATKINSON.

(*Concluded from page 592.*)

Resistances for Regulating Dynamo and Motor Shunts.

Almost any of the forms are suitable for this purpose. As to capacity, the maximum amount of power to be dissipated is reached when the resistance is equal to the resistance of the shunt, and when the current comes down to half its original value.

Resistances working by compression, and therefore giving a perfectly steady graduation between maximum and minimum, have the advantage of allowing the E.M.F. to be regulated very exactly, an advantage where dynamos are being run in parallel.

Arc Lamp Resistances.

These form an important class, as very large numbers of them are used.

The usual form consists of a porcelain cylinder, having a spiral upon it, in which is wound a German silver wire. The resistance is regulated by a movable clamp, placing more or less of the wires in circuit.

Three forms of arc lamp resistances were designed by the writer some years ago, in each of which the base is an iron cylinder covered with asbestos, on which the resistance is wound. All these forms of resistance have the disadvantage that as the wire is heated and cooled it is subject to very considerable strains, and the wires are frequently fractured.

In that form of arc lamp resistance in which "Relugite" is utilised as the resisting material, and the resistance is adjusted, as required, by tightening or slackening the end on the top.

An important advantage possessed by this latter form of resistance is that as the coefficient of temperature variation is negative, the resistance is higher when first the current is switched on than it is when the arc has been burning a short time, and the resistance becomes warm, thus assisting in keeping the current to its normal value, whilst the arc becomes of a proper length.

Resistances for Lowering Lamps.

These are mostly used for stage effects, and if made with switches, should have a large number of contacts to make the graduation imperceptible, or liquid resistances or resistances worked by pressure variation should be used.

Owing to the peculiar nature of the fire risks in the theatre, special care should be taken that the rise of temperature should be small.

In the case of resistances designed by the writer for the Drury Lane Theatre, the specification was that the resistances should not rise more than 80° F. above that of the atmosphere.

Resistances for Meter and Instrument Testing

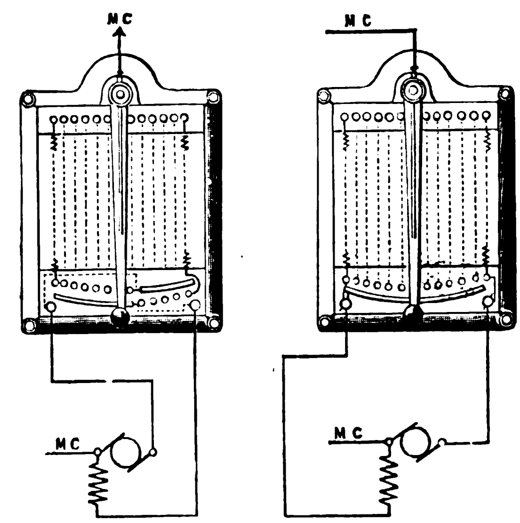
For this purpose resistances with sliding wire, or liquid resistances, have been generally used, enabling the current to be kept at an *exact* value. The "Relugite" pressure resistances is now being adopted for this purpose. It has the additional advantage with alternate currents, that the resistance being inductionless no errors are introduced.

Motor Starting Resistances.

It has frequently been a subject of complaint that the resistances for starting both continuous current and multiphase motors, particularly for small powers, cost almost as much as the motor itself. This has been largely due to want of standard designs specially suited for the purpose.

In general the resistance is not required for more than, say, one minute, but should be capable of carrying the full load of the motor for that time. Some forms recently introduced will only carry the load for 20 seconds; this is not safe.

For the purpose of regulating the speed of motors the resistances must be made larger, and must be capable of carrying a load depending on the range of regulation, but if this is a wide one practically the full load of the motor must be provided for. The simplest way of regulating the speed of a shunt motor is shown in the right-hand diagram, where a resistance is placed in circuit with the armature of



M C Main circuit.

Starting resistance with shunt regulation. Starting resistance without shunt regulation.

the motor, the full line pressure always being on the shunt coil. The left-hand diagram, a modified arrangement, in which part of the speed regulation is effected by varying the strength of the current in the magnet coils. In this case the method of working is to have, in the first instance, the full line pressure on the magnet coils and resistance in the armature circuit. The resistance is gradually taken out of the armature circuit, and resistance is then inserted in the magnet circuit, thus weakening the field and allowing the speed to rise.

If this form of regulation is to be adopted, the magnet windings should be specially arranged for the apparatus to have a low resistance, so that the motor is considerably over excited at starting.

In order to avoid the possibility of a motor being switched into circuit rapidly, it is preferable to fit such resistances with a screw motion, but if this is done arrangements must be made by a separate switch or otherwise, so that the circuit can be broken instantaneously in the case of accident or emergency.

An important point in connection with regulating resistances, particularly where the variation in resistance from point to point is considerable, is the question of the switch contacts, as considerable sparking occurs on the contacts, which, from this cause, become dirty or roughened, and causes considerable trouble.

In a form of switch pillar for starting and regulating speed of motors designed by Messrs. Royce, independent quick-break contacts are fitted at each resistance point, and the final break is effected by a carbon contact. In a form designed by Pochin, the switch arm itself carries a small wiper which takes the spark, and it may be renewed as required.

In the case of pressure resistances these precautions are unnecessary, and even in the case of resistances with multiple contacts and filled with "Relugite" material, owing to the fact that such resistances are inductionless, the spark on the contacts is practically eliminated.

Conclusion.

In conclusion, the writer desires to point out the advances which have taken place in the last few years in the design and manufacture of resistances, owing largely to the increased demand, and therefore to the specialisation which this has allowed, and hopes that the notes contained in the foregoing paper will prove of interest to the members of the Northern Society of Electrical Engineers, who have doubtless had considerable experience not only of the merits, but of the disadvantages, to which this class of apparatus is liable.

From a manufacturer's point of view, it is greatly to be desired that engineers designing plants will endeavour to avail themselves of manufacturers' existing patterns and standards rather than to specify for particular arrangements, as it is only in this way that the cost of accessories of the electric light and power plants can be brought to a point which will have the effect of greatly stimulating the use of electrical appliances in many cases where at present the admitted advantages do not outweigh the expenditure necessary.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

EARTH RETURNS FOR ELECTRIC TRAMWAYS. By H. F. PARSHALL, member. Paper read April 28th, 1898.

Considering the small difference of potential at which electrolytic action may take place, a matter of primary importance in electric tramway systems in which the rails are used as return conductors, is in reference to the rate of fall of potential, and the difference of potential between the rails and the general mass of earth, the magnitude of which may vary according to such local conditions as the locality of gas and water pipes, the conductivity of the earth between the rails and such pipes, and the conductivity of the pipes themselves.

The exposed surface for leakage of the track is very great; thus in the ordinary four-track tramway system there is some 50,000 feet per route mile. With so great a surface, and with, as is generally the case, considerable conductivity of the concrete and earth, a large fraction of the current may be diverted from the rails, even in short lines, and with a maximum drop as small as that specified by the Board of Trade.

Thus, in tests recently carried out in a line some 8 miles long, it was found, by cutting the track at the middle of the line and inserting an amperemeter, that some 60 per cent. of the current was returning through the earth itself. Tests made as to the conductivity of the earth return showed as a whole that it was about one and a half that of the rails, bonds, and fish-plates, which would indicate that on an average about 33 per cent. of the current was leaving the rails. In other words, the voltage drop in the earth return was but two-thirds of what it would have been had the current been wholly in the rails.

In laying the rails, therefore, it seems desirable to adopt such methods of construction as will, to a considerable extent, insulate the rails from the adjacent mass of earth. The conductivity of the earth is considerable, and with differences of potential up to the limit established by the Board of Trade is so great that, in the cases I have examined, stray currents are not diverted from the mass of earth by gas and water pipes. I have made tests by cutting the rails and measuring the currents at different points, and, so far as could be determined, the neighbouring gas and water pipes were not traversed by the current. In one special case two lines of the tramway formed two sides of an acute angle triangle, and a very large water main formed the third side, and even though some 50 per cent. of the current did not come back through the rails, the tests showed beyond doubt that there was no current whatsoever coming across the third side of the triangle through the water pipe. Of course, with the small difference of potential common in practice in this country, the C.E.M.F. of polarisation which accompanies currents flowing between conductors when electrolysis takes place is an important element in determining the law of current-flow.

The tests carried out by the writer have in every case shown that the joint conductivity of the rail and the earth is considerably greater than that of the rails themselves. For this reason there exists the necessity of determining the conductivity of the rails, fish-plates, and bonds, before the track is laid in the earth, so that after a roadway is completed the measured drop may be taken as an indication of what percentage of current is straying from the rails; further, so that tests made from time to time may indicate the general condition of the bonding.

In general it is desirable that the earth return be isolated to the greatest degree practicable from any other metallic conductors liable to be affected by electrolysis. In some cases, however, where the drop in the earth return has been comparatively great, attempts have been made to prevent electrolysis by bonding the rails to the adjacent gas and water pipes. The results have been more or less satisfactory. It is obvious that, if the rails and adjacent gas and water pipes can be kept at the same potential, electrolytic action can be effectively prevented. Considering, however, the very considerable conductivity of the earth, it would seem doubtful whether such bonding would prove effective with any considerable drop in the rails, since in this case stray currents would flow from one part of the system to another, and at such a difference of potential as would cause electrolysis.

In the case of lead-sheathed cables running parallel to earth returns of tramways, the results have been entirely satisfactory and are conclusive, since, in the absence of bonding, the lead sheathing was rapidly eaten away. This instance, however, is not to be relied upon as an indication that it would be safe to carry out the same process in dealing with gas and water pipes. The lead sheathing is homogeneous, of comparatively high resistance, and with small surface exposed to the earth, whereas the reverse holds true with gas and water pipes as ordinarily laid down. I have no doubt that there are cases in which effective bonding of the rails adjacent to conductors might give entirely satisfactory results, but I should hesitate to make any general recommendation to this effect, since in very many cases a result directly opposite might be obtained.

There is such a difference in soils—first, as to corrosive properties; second, as to electrical conductivity—that a general rule which would prevent electrolysis in every case would be unnecessarily severe, and in many cases prohibitive. It is obvious that, where currents stray generally into the earth so as to enter metallic conductors, the difference of potential should not be allowed to exceed that at which electrolysis begins, + the drop in the earth itself.

In a given system of distribution the controllable features in the earth return are practically limited to the method of jointing the cross section of the rails, and the chemical composition of the rails.

The chemical composition of the rails cannot be altered greatly, since rails low in carbon, but of high electrical conductivity, are found to wear away so rapidly that high carbon rails are a practical necessity.

The cross section of the rail in practice is largely determined from mechanical considerations, and in the best practice rails of from 80 to 100 lbs. per running yard are used.

The method of making the rail joints is practically, then, the only factor controlling the resistance of the rail return that is susceptible to wide variation in practice.

The electric welding of the rail joints has been tried in the United States, but thus far the results have not been such as to encourage the manufacturers to advance the use of the system, or the tramway companies to adopt it.

The joints in electrical tramway work are equally objectionable from either a mechanical or electrical point of view, so that a system of perfectly welded rails would meet with general favour. In practice the effect of temperature in causing expansion and contraction has been noticeable in long lengths of welded rails, but the effects thereof have not been of such a serious nature as might be expected from the range of temperature.

From the reports I have at hand it appears that there were unexpected results of the welding process that made themselves evident in the course of time.

First, the electrical conductivity of the welded section was less than that of a solid rail.

Second, the portions of each rail near the weld were so softened as to wear away unevenly.

Another unexpected result was that, owing to the sudden increase and decrease in temperature, the rail took a very high temper at the weld, so that its power to withstand shock was decreased.

To the writer's mind it is not improbable that these mechanical difficulties could be overcome. Welding apparatus of sufficient capacity, however, is costly, and it is frequently difficult to arrange for the amount of power required; so far, therefore, the process has not been employed in this country.

Another method of somewhat the same nature as the process of welding is that known as the "cast weld," or the "Falk joint." This joint is made by pouring molten metal into a metal mould clamped round the rail joint. The surfaces of the cast metal that come in contact with the mould and with the rail joint are chilled, and are thus prevented from forming a perfect weld. I believe it has been asserted that a weld is effected. It seems, however, extremely doubtful, since without the use of a flux a weld is almost impossible between cold wrought steel and molten iron. The rail expands after the metal is poured around it, and remains expanded until after the cast-iron has set, and finally resumes its former size. This affords a slight clearance for expansion and contraction, and accounts for the mechanical success of the joint, which, if carefully applied, makes when new a perfect mechanical track; although, in the writer's mind, the difference of resilience between the part surrounding the casting and the remaining part of the track may eventually cause uneven wearing away of the rail.

The clearance above spoken of undoubtedly admits a certain amount of moisture, so that by the formation of oxide the resistance of the joint increases in the course of time. From the results of tests which I have at hand, it also appears that the electrical resistance of this joint, even when new, varies considerably; so that, considering the low voltage restrictions in this country, it should be used in connection with an efficient form of bond. Owing to the rigidity of the joint, however, copper bonds will undoubtedly be found more durable in conjunction with it than with a fish-plate form of joint.

Bonds.

The bonds generally used up to this time are of the pressure-contact type, and in making any general statements this is naturally assumed as the basis.

In the discussion of a paper read some time ago before this Institution, the writer pointed out that, according to experience with pressure contacts in central station work, 100 amperes per square inch had been found the limit in best central station practice; and that, considering the trying conditions to which bonds are subjected in the earth, one-half of this value would more likely be satisfactory.

In actual practice I have found it advisable to work to a still lower limit, and in most of the systems which I have designed the current-density at surface of contacts does not exceed 25 amperes per square inch. Experience shows this limit a safe one, and that the contact resistance is negligible as compared with the resistance of the rails.

Considering the complicated phenomena accompanying a junction of copper and iron, in respect to the difference of potential caused by the contact of dissimilar metals, and the effect due to a current passing between dissimilar metals, it seems in the normal case that all E.M.Fs. would balance each other, since in the case of the current keeping uniformly through the rails the E.M.Fs. at the positive ends of a bond are balanced, and in the case of one end of a bond losing its contact the additional resistance would be greatly in excess of the unbalanced contact E.M.F.

The design of copper bond should be largely in reference to the permanency of the contact surface. If there is any working between the surfaces, sooner or later there will be a film of oxide, so that the value of the contact is destroyed. The working of the surfaces may be caused by heating from excessive current density, or by lack of flexibility in the bond. Numerous types have been forthcoming. Many of the bonds brought forward during the last two or three years have been designed with a recognition of the importance of greatly increasing the area of the contact surface, as compared with the cross-section of the body of the bond itself.

It is beyond the scope of this paper to discuss all the different types of bonds that have been brought forward from time to time. Samples of many of the different types are exhibited. The copper bonds that the writer has tested, since they have been more generally used in this country, are either of the "Chicago," "Crown," or "Columbia" type, samples of which are before you.

Flexible bonds are found desirable for use where the mechanical conditions are such that short bonds can be used, in which case the added resistance of the bonds to the track can be made as low as 5 per cent., or less. Bonds of this type have been frequently used in the United States, and with good results when the ends are made of drop forged copper. When, however, the ends have been made of cast copper, and cast on to the conductors, the results are not generally satisfactory. The resistance of cast copper is so much greater than that of drawn copper that it is not best suited for use in bonds. Further, the union between cast copper and drawn copper wires is imperfect, so that the electrical resistance is much higher than between two pieces of pure copper fused together.

The remaining type of bond that I propose to discuss is that known as the "plastic" bond, which was invented by Mr. Edison several years ago. From the results obtained from a line bonded over five years ago, it appears that this plastic alloy, which consists of mercury and other ingredients, as to the nature of which I am uninformed, is much more permanent than might be expected from its mechanical nature. The bond is placed between the fish-plate and the rail, in a cork receptacle, which is compressed to about half its thickness when the fish-plate is drawn up tightly.

The amount of copper required materially to increase the conductivity of well-bonded rails is so great that in ordinary practice auxiliary track feeders are not commercially practicable, unless they be connected in circuit with a source of E.M.F. to compensate for the drop in the feeder, so that this may exceed that in the track return.

I believe Major Cardew was the first to suggest employing E.M.Fs. in feeders to compensate for the drop therein. In the arrangement, however, of the earth return as originally devised by him, it was necessary to use generators of different E.M.Fs. in the generating station. I have used in my work a generator that is separately excited through a coil in series with the trolley feeder, so that the voltage generated by the armature is directly proportional to the current-output, provided the field magnet is not saturated. The armature is in series with an insulated feeder connected with the rail at whatever point it is necessary to take off current. The results in practice are most satisfactory. It has been found that the machine works perfectly automatically, and limits the voltage drop in the earth return to any desired amount by an adjustment of a rheostat in parallel with the field-magnet coil. Fig. 1 gives a diagrammatic representation of the system.

In a system that I have recently designed to carry some 250 cars, I propose to employ several earth generators feeding in from several points in the system. Pairs of test wires are run back to the station from various points, one of the test wires being connected to the track return, and the other to adjacent earth plates. The earth generators in the station will be adjusted from time to time, according to the difference of potential between the earth plates and the earth return. As far as possible the adjustments will be made so that the two are kept generally over the system at the same voltage.

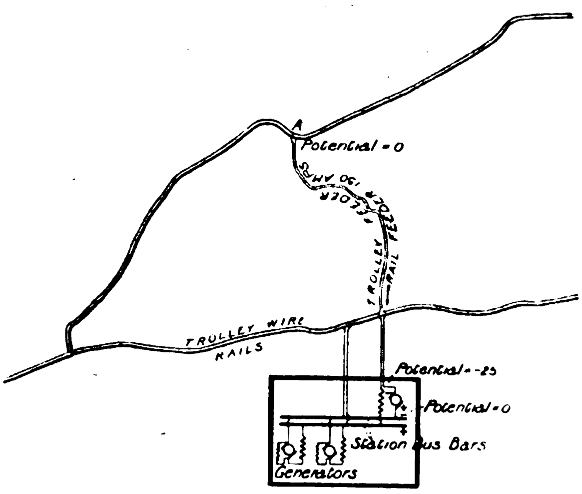

Fig. 1.—Return Booster System.

Whatever difference of potential there is between the two, will be such that the earth return is, in general, positive to the neighbouring water or other pipes, since in this case whatever electrolysis takes place will be in the track return itself.

Steel Rails.

The percentages of carbon, manganese, &c., in steel rails have varied considerably at different times; and there are, even now, wide variations in the practice of different companies, and in different countries.

It may be said that English rails some years back would commonly contain the following:—

Carbon	0·25 to 0·35
Manganese	0·8 „ 1·0
Silicon	0·05
Phosphorus	0·06
Sulphur	0·06

Of late years the percentage of carbon has increased. One large railway company specifies:—

Carbon	0·4 to 0·5
Manganese...	0·95 „ 0·85
Silicon	0·10 „ 0·06
Phosphorus	0·10 „ 0·08
Sulphur	0·08

In American practice the carbon runs still higher, as will be seen from the following:—

Carbon	0·45 to 0·55
Manganese	0·8 „ 1·0
Silicon	0·10 „ 0·15
Phosphorus	0·06
Sulphur	0·06

In France yet higher percentages of carbon have been tried, running up to nearly 1 per cent.

The results are shown in the following table—trials of some sample sections of steel rail of varying compositions which were furnished for testing purposes:—

Carbon.	Manganese.	Silicon.	Phosphorus.	Sulphur.	Resistance compared with copper 20° C.	Resistance of 1 mile 1 sq. in. sectional area at 20° C.
0·378	0·550	0·181	0·040	0·041	10·8	0·468
0·446	0·568	0·188	0·046	0·044	11·1	0·482
0·536	0·592	0·201	0·051	0·059	11·3	0·490
0·568	0·608	0·204	0·053	0·061	11·4	0·495
0·588	0·632	0·214	0·056	0·065	11·5	0·499
0·610	0·650	0·220	0·062	0·071	12·9	0·560

Eight 76-lb. track rails, tested in place after 2½ years' use, gave the following results:—

	Resistance compared with copper 20° C.	Resistance of 1 mile 1 sq. in. sectional area at 20° C.
Test No. 1	11·3	0·490
„ „ 2	10·3	0·447
„ „ 3	10·1	0·438
„ „ 4	10·7	0·464
„ „ 5	9·65	0·419
„ „ 6	10·07	0·437
„ „ 7	10·25	0·445
„ „ 8	10·50	0·455
Average ...	10·4	0·45

Two old 65-lb. rails, much worn, tested in place:—

	Resistance compared with copper 20° C.	Resistance of 1 mile 1 sq. in. sectional area at 20° C.
Test No. 1	11·7	0·508
„ „ 2	12·3	0·534
Average ...	12·0	0·52

High values would be expected owing to the wearing of the rail, which is not allowed for in the calculations.

Two new 90-lb. rails, tested in place:—

	Resistance compared with copper 20° C.	Resistance of 1 mile 1 sq. in. sectional area at 20° C.
Test No. 1	10·6	0·460
„ „ 2	10·4	0·451
Average ...	10·5	0·455

A 66½-lb. rail not laid:—

	10·0	0·434

Bonds.

The current flows across the joints partly through the fish-plates, and partly through the bonds. The resistance of the fish-plates is a variable quantity, but all tests on rails in use have shown that they contribute considerably to the conductivity of the joint.

For the bonds themselves the following tests have been made:—

(1) Conductivity tests on bond copper.
(2) Resistance due to contacts.
(3) Resistance due to current "gathering" from other sections of rail to enter the bond terminal.

(To be continued.)

ELECTRICAL ENERGY (GENERATING STATIONS AND SUPPLY).

(Continued from page 578.)

Lord Cross (chairman) presided over the sitting of the Joint Committee on Thursday, when evidence was given by Mr. James Swinburne, consulting engineer, and Vice-president of the Institution of Electrical Engineers, upon the fourth head of the reference to the Committee, viz., "Whether powers should be given in any case for the supply of electrical energy over an area including districts of numerous local authorities involving plant of exceptional dimensions and high voltage; and, if such powers may properly be given, whether any and what conditions should be imposed—(*a*) with respect to system and plant, and to the construction and location of generating stations in view of the powers of purchase conferred upon local authorities by Sections 2 and 3 of the Electric Lighting Act of 1888; (*b*) with respect to the relations of the promoters to other undertakers, and to local authorities within parts of the area."

Witness, examined by Mr. Pember, Q.C., said that it was now being realised by capitalists that electrical energy could be safely and cheaply conveyed a long distance by wires, and there was nothing to prevent the general development of the distribution of power from the pit's mouth, the only thing remaining to check such industrial development being legal difficulties. They could carry extra high electric pressure by comparatively small wires to various places where there was a demand. Overhead wires were used abroad, but in this country only underground wires would be employed. Such systems could supply power at a long distance and over an enormous area. In order to supply such an area there would be local transformer stations or sub-stations, which would be comparatively small affairs, and there would be no smoke, steam, or vibration. Electrical progress was disgracefully behindhand in England, one reason being that it was not realised as it should be, that distribution was as good in the case of coal as in that of water power; the novelty, from the engineering point of view, was practically nothing. He had considered how far an extended distribution was necessary for the purpose of cheapness. He would not say it was a necessity, but it would be an advantage. Besides lighting, there was the question of energy for motors and tramways and light railways. It frequently happened, if there was a central supply, many small villages and towns could be lighted, because the capital cost would only be for distribution. That would be especially advantageous in the Black Country. There was an extreme case to be considered in the fact that looms could be worked by motors. There was no doubt also in the future, that mills and engines, and so on, would be driven by motors. He had lately inspected one of the largest electric factories in Berlin, and found between 6,000 and 8,000 people employed making about 30 dynamos and motors a day. The majority of these motors were for the purpose of driving machinery. For cotton spinning, where uniform speed was an essential, a motor would be preferable to an engine. For all such things as these the central supply would be the cheapest way of bringing the current. With regard to the protection of the consumer, he thought competition might be allowed if the district was served badly either in the way of price or distribution. Local authorities had the chance of competing on exceptional terms with other people. He saw no need for a monopoly being given to any company. All sorts of people scattered about could get power, such as farmers, to drive threshing machinery, and even in an extreme case, it might pay to light up the harvest field all night. A thing managed on a large scale could be worked cheaper than on a small scale. In the case of a town supply, if the local authority worked a station properly there was no reason for the scheme of supplying power in bulk to come in; but if the station was not worked properly it would be to the advantage of the ratepayers to have a supply in bulk. The only thing which it would be to the advantage of the local authority to purchase would be the low pressure distribution; but even then the conditions were not the same as in the case of an ordinary electric light company. He thought if the local authority had the power to purchase in 42 years they would get a much better bargain than in an ordinary case.

Mr. PEMBER: You think such a distribution would be a great public and commercial benefit?—Yes, and it must be considered from a public and commercial point of view, and not from a parochial point of view.

And you see no reason why there should not be compulsory purchase of land for a generating station as much as in the case of a railway station?—I think there is more reason in this case.

Proceeding, WITNESS said there should be power to break up the roads. It only involved the taking up the roads once to lay down the mains.

Mr. COWARD: The position of the local authorities is this. Should such a scheme as you suggest be authorised without the consent of the local authorities within the area of supply. Is that your view?—I do not see why you should get the consent of, perhaps, 150 local authorities.

Further examined, WITNESS said that he saw no reason why there should be the consent of the local authority in the area where the generating station was erected, because places could be chosen where there could be no nuisance. Some years ago he worked out a scheme of transmitting power from the Midlands to London, and it would pay perfectly. He did not think they could make general principles of purchase fit in with regard to London as could be laid down with respect to the country, because the conditions were so different. He saw no reason why it should not be laid down that the local authorities should fix the route which mains should take, subject to an appeal to the Board of Trade, and also that the local authorities might carry out the work at the expense of the undertakers.

By Lord SPENCER: The chief disturbance to telephones and telegraphs came from electric traction, and no difference could ensue from the supply coming from a distance. He would give the local authority every kind of notice and right to appear before compulsory purchase was adopted.

Questioned by Mr. KIMBER: The cost of coal might be considered the governing power in the supply of electricity. He thought special conditions would have to be imposed with respect to the danger of high voltages, but such conditions could be easily met. It would be fair that notice should be given to the neighbouring owners of the intention to build a generating station. In many of the modern generating stations there was no vibration at all.

Replying to Lord KNUTSFORD, WITNESS said that some protection should be given to the consumer in regard to price, possibly by a reference to the Board of Trade.

By Lord BALCARRES: High pressure and extra high pressure mains were carried overhead abroad. It was a danger, but he thought too much was made of it. It was certainly not the case to say that the carrying of such mains overhead was the cause of considerable loss of life. He would not recommend the carrying of overhead mains in towns.

By Lord MONKSWELL: It would pay to supply London from the Midlands, because of the saving in the cost and handling of coal. He thought the ordinary law of nuisance should apply to electric lighting companies in towns.

Questioned by the CHAIRMAN, WITNESS said if they got the power to erect these large generating stations, they were safe from purchase.

Mr. HENRY GRAHAM HARRIS, partner of Sir Fredk. Bramwell, said his firm had erected several electric stations. They had been consulted with regard to the supply of electricity at high voltage from long distances, and the supply to a large area from a central station would be economical, and would lessen the price to the consumer. There were several grounds of economy. The management expenses would be less, and the cost of the installation of the works per unit would be less. Larger units of machinery were cheaper, proportionately. The cost of collection would also be less. The current could be used for various purposes besides that of lighting. He agreed generally with the evidence of the preceding witness.

Questioned by Mr. COWARD, WITNESS said he agreed with the evidence of the previous witness that the local authority should have the right to direct the route of mains in their streets.

By Mr. KIMBER: He thought the sliding scale of the gas companies was a good thing, but the question was that there should be no purchase if the scale was adopted with electric lighting companies.

By the CHAIRMAN: Before the Electric Lighting Act of 1888 extended the time to 42 years, it was not worth while for capitalists to put their money into such undertakings, because the period was not sufficient and the risk too great. It was extremely doubtful now, in some cases, whether 42 years was sufficient, but in a large number of cases it was sufficient.

Mr. JOHN FRANCIS ALBRIGHT, chairman of the Midland Electric Corporation Scheme, said his view upon giving a power to a company to supply wholesale was, that it was important to a company like he represented to have the power to supply to corporations for lighting purposes. At the present time the company was in a dilemma, because, whereas they contracted with the corporations to supply them only, yet, under the law, they were called upon to supply all demands. He did not say that such corporations as Manchester and Liverpool could not supply as cheaply as a large company, but a small local authority could not do so.

By Mr. KIMBER: He would not object to the sliding scale. He could not say at what price the London companies could supply light, because the conditions were so different.

By Sir ALFRED LYELL: In London there would never be the same demand as in the Black Country.

Mr. PEMBER said that would conclude the case for the companies.

An argument took place with Mr. STEVEN (representing the present companies) as to calling witnesses, and it was decided that he should not.

Mr. CRIPPS (Parliamentary Agent) asked that the Metropolitan Electric Lighting Company should be heard. That company was the largest in London, and as Mr. Pember was representing a combination of competing companies their interests were not identical.

The CHAIRMAN said the Committee would hear counsel for the company on any new point.

The Corporation witnesses were then called.

Mr. HIGGINBOTTOM, Alderman of the city of Manchester and chairman of the Corporation's Electricity Committee, was first called. He said that the Corporation had power to supply energy to the whole of the city, and they were also the undertakers of surrounding communities. The demand had become very great. Manchester had always maintained that the Corporation should have sole and absolute control of the streets. Gas, electric lighting, and hydraulic power were all supplied municipally. The duplication of electric mains would be extremely undesirable. The electric supply in Manchester had been a very profitable undertaking from the first. Local authorities ought to have power to acquire land compulsorily, and companies should be in the same position. Electrical undertakings should be exempt from proceedings for nuisance, where proper care was exercised. As far as possible, all stations should be confined within the area of supply, and in laying mains between an outside generating station and the area of distribution, the local authority should have the right of determining the route of the mains, and of itself doing the work of laying down if it so wished. The consent of the local authority should be necessary to any undertaking for the supply of electrical energy, and the right of purchase given under the general Act should remain. The case of London, he thought, was quite different from that of the other great provincial towns.

Lord Cross presided on Monday over a further sitting of the Joint Committee.

Sir SAMUEL JOHNSON, Town Clerk of the city of Nottingham, which had a population of 230,000, said the Corporation already possessed the gas works, and they supplied gas to an area of 100 square miles outside the city boundary. They also owned the water and the tramways. They started an electrical undertaking four years ago, so as to maintain their authority over the streets. It was not thought that the electric station would pay at first, but it had been a great success. They made a profit both from the gas and water. Last year they made £33,000 odd profit from the gas, most of which was due to the city. They attached great importance to the control of their streets. They agreed that Corporations should have compulsory power to purchase land for generating stations. In other words, they asked to be put on the same footing as other undertakings where power was given to acquire land compulsorily for the public benefit. He was authorised to speak for Lincoln, Rotherham, Chesterfield, Doncaster, and some 12 other cities, and the strong feeling of all those places was that they should keep the control of the streets, and that they should not be given up to dividend-seeking companies. There was no objection to the Board of Trade dispensing with the consent of the local authority, if it were shown that there were no good grounds for refusal to allow the streets to be opened.

By Mr. PEMBER: They supplied their largest consumers with electricity at 2⅜d. per unit. Ordinary consumers were charged 6d. for the first hour. They had about four miles of subways, through which all pipes were carried. The reason he referred to dividend-paying companies was that their chief object was to pay a dividend, and not the public convenience. According to the practice of the Board of Trade, his Corporation had the monopoly of the supply of electric light. In the case of a central supply company wishing to carry a main through their streets, and not to supply the city, they did not object to their consent being subject to the Board of Trade. They committed no nuisance whatever in respect of their generating station. He thought that notices of an intention to acquire land for an electric generating station should be served on occupiers within a radius of 50 yards.

Examined by Mr. BALFOUR BROWN, WITNESS said applications had been made for their consent to electric companies coming into the city, but having invested the ratepayers' money in an electric light undertaking, they did not see why a company should come in. If the Corporation were not doing their duty they should not be exempt from competition.

By Lord SPENCER: When he said the Corporation should have a veto regarding the breaking up of the streets, he meant that that should be subject to the Board of Trade or Parliament. The Corporation had not at present contemplated supplying electric light outside their area. They could generate all the power they required in their own area, but in the case of an authority being unable to generate within its own area, there should be power to carry a main through other areas, subject to conditions.

Questioned by Mr. KIMBER: Their powers with regard to electric light were conferred by a provisional order. It seemed a fair proposition that they should have compulsory powers for the acquisition of land for generating stations. At present they did not supply power; not because they could not do so as cheaply as steam, but simply because there was no demand for it before. Now they intended applying electrical power to the tramways, and the matter was now before the Corporation. They would be able to supply electrical power cheaper than the light, because there would be a day load.

Lord BALCARRES: If a great demand arises for energy in your city, are you convinced that the municipality will be able to meet that demand?—Certainly; to the uppermost.

Your municipality desires a monopoly?—Yes, the same as for gas.

By Mr. ASHTON: The municipality did not appear to have protection in the outside area they supplied with water in respect of interference by electricity. He had heard that 10,000 to 20,000 volts was contemplated being passed through mains, and in that case, in a county like theirs, liable to be broken up by mining operations, the water pipes might be damaged, and the supply to the town stopped.

By Lord MONKSWELL: The objection that manufacturers would not take power from the Corporation because of business secrets leaking out he did not think would hold good, because at present they supplied gas power to manufacturers.

By Mr. KIMBER: His Corporation was opposing the Bill of the General Power Distributing Company.

Further examined by Mr. PEMBER, WITNESS said that after paying off all preliminary charges, and providing for all costs, and all charges such as rates and taxes, interest on money and sinking fund, they made a profit in the first year of £500, and in the next year a profit of £2,200. Then they reduced the price of the light to the extent of £2,000, but still made a profit of £3,600. They were seeking to double their station now, and if they did that, and the demand for light still continued, they would be able to reduce the cost. They had 35,000 8-candle-power lamps, and supplied 4,800,000 units.

Mr. GEO. FRANKLIN, Lord Mayor of Sheffield, said that the Corporation had agreed to purchase the undertaking of the Sheffield Electric Light and Power Company, and they were promoting a Bill in Parliament to affirm the agreement for the purchase. They were opposing the Bill of the General Power Distributing Company. The generating station in Sheffield was situated almost in the centre of the town, and had been running about 12 years with absolutely no complaint as to nuisance. They got a plentiful and cheap supply of coal, and so far as Sheffield was concerned, there would be no advantage in having a huge generating station at the pit's mouth. He agreed as to compulsory powers being given for the acquisition of sites, and they deprecated any interference with the streets. He agreed generally with the evidence of the previous witness.

By Mr. RICKARDS: He thought that municipal corporations could undoubtedly carry out industrial undertakings as economically as private companies. Sheffield was indebted to private enterprise for the starting of an electric undertaking.

Questioned by Mr. KIMBER, WITNESS said that the present Sheffield Company did not supply power, but the Corporation intended to do so, and were making arrangements to work the tramways by electricity. He did not think electricity would be more economical to manufacturers in Sheffield of armour plate and things of that sort. The maximum charge of the Sheffield Company was 4d. per unit, and last year they supplied three-quarters of a million units. With the increase of output and the equalisation of the load, the Corporation hoped to decrease the price considerably. They hoped to bring down the cost in two years to 1d. per unit.

By Lord KNUTSFORD: So far as the mere breaking up of the streets was concerned, they would not object if the work was left in the hands of the Corporation.

Examined by Lord BALCARRES: Two years ago the Corporation would have objected to competition, because when the company went to Parliament an agreement was arrived at with the Corporation.

By Mr. ASHTON: A newspaper notice should be sufficient for neighbouring occupiers of intention to take land for a generating station.

Dr. JOHN HOPKINSON, F.R.S., and past-president of the Institution of Electrical Engineers, said he agreed that both companies and local authorities should have compulsory powers to acquire land for generating stations. With respect to breaking up the streets, the local authority should have the power of withholding their consent, subject to the action of the Board of Trade. The reason that the charge for power could be less than light was that those using power used it for a longer period.

By Mr. KIMBER: He came before the Committee at the instance of the Corporations. He was frequently consulted by electric light companies, and was connected with the Metropolitan Electric Light Company.

Questioned by Sir LEONARD LYELL, WITNESS said there was undoubted risk to gas and water pipes by the working of electrical tramways, but the Board of Trade had laid down conditions which would prevent that, and a careful engineer would take even greater precaution.

By Mr. ASHTON: There were dangers in a town from overhead electric wires, but much greater freedom might be permitted in the country with regard to overhead wires.

Lord BALCARRES: Do you think these great general distributing stations have in them the elements of success?—When their power is very cheap I think they have. In the case of coal I do not think it makes much difference, as coal can be easily carried.

The CHAIRMAN: Supposing you were an autocrat, and had to supply a large industrial area with the cheapest power, would you advocate one central station in one particular place, or a number of them?—A great many. Of course, you must take the particulars of towns into consideration. In the case of London there would be a difficulty of getting a site.

If you had to make a fresh start with London, what would you do?—If I had to make a start with all the experience we have had, I should put the stations outside.

Would you put up one station for the whole of London?—No; probably two or three.

On the ground of economy, how many stations would you have?—I do not think there would be much economy in having only one station, except as regards rent.

But suppose you get the land cheap for the supply of London, how many stations would you have?—Five or six.

Sir ALEXANDER BINNIE, chief engineer to the London County Council, said that at the present time there were in London 26 bodies authorised to supply electrical energy, 14 of which were companies, and 12 local authorities. Of the local authorities with electric lighting orders, five were supplying the areas shown. In consequence of the crowded condition of the streets, the matter was becoming serious, and would have to be dealt with in a more thorough manner than it had been.

Mr. J. W. BENN, chairman of the Highways Committee of the London County Council, described the powers which that body had over the companies in regard to opening the streets. The companies had to ask the consent of the County Council.

By Mr. BALFOUR BROWNE: He quite understood that the Board of Trade was the final authority as to opening the streets. The County Council had no power to purchase any portion of the electrical plant in London.

Questioned by Earl SPENCER: It was quite peculiar to London that the London County Council, while having certain powers over the Electric Light Company, had no power of purchase. He thought they certainly should have power of purchase. In the event of such power being given, they would ask for the power to erect stations outside their own area, and they had a precedent for that in the case of the sewage system.

By Mr. KIMBER: With respect to the proposals to supply energy in bulk, it seemed to him that the power of purchase was valueless to the local authorities.

By Lord CROSS: The County Council would reduce the price of the light before relieving the rates if they owned the electric lighting companies. Municipal ownership was, however, their chief object.

The CHAIRMAN: I thought so.

Earl RUSSELL, late chairman of the Highways Committee of the London County Council, said that if a central supply system was to come in, the power of purchase would have to be in the hands of the central authority.

By Lord BALCARRES: There was no suggestion that the local authorities should be deprived of the right they had now to buy up electric light stations after a certain number of years.

Mr. W. H. PREECE, chief electrician of the Post Office, said that generating stations were required for other purposes than those which had been brought before the Committee. They had been told of the supply of energy for lighting and power purposes which were growing at a considerable rate; but besides that there was the working of tramways, the supply of current for charging batteries for cabs and vans in London, and also generally for traction purposes. Then again, there was a very important field about to be opened, which was the working of existing railways by electricity. The Metropolitan District Railway had obtained a Bill, which had passed through one House, to enable them to work their railway by electricity. In the future, also, electrical energy would be used largely for chemical manufacture and the production of heat. These were things which showed that the construction of these central stations required legislation conditions. Their attention was first called to the nuisance likely to arise by the interference with telephones. Now the Telephone Company had learned wisdom, and the practice was invariably to make the telephone circuit a metallic circuit. With telegraphs it was quite a different matter, for with the enormous system it was impossible to duplicate the wires. Disturbances had been caused at Greenwich Observatory by the City and South London Railway, and at Liverpool by the Overhead Railway. All those disturbances could, however, be remedied. There was one difficulty which up to the present had not been entirely removed, and that was in the working of tramways by the trolley wire system. From them loose currents ran about which affected water pipes and gas pipes. There was no doubt, however, that with stringent clauses appointing proper control these disturbances would ultimately be removed also.

Do the power houses cause nuisance?—They might, but they are remedial. There is, of course, the cartage of the coals and the removal of the ashes, which cannot be avoided.

But vibration with these new engines can be avoided altogether?—Yes.

So that, practically, there is no nuisance?—The only nuisance is possible vibration from neglect.

The operation of opening streets might become a nuisance?—Yes, I would keep that under the local authority.

If you had to start afresh with London, how many stations would you have?—I think London could be served for all purposes if we had four large central stations. Two or three on the banks of the Thames, or two or three on the main railways. That would remedy almost all the difficulties I have enumerated.

Continuing, WITNESS said that the Manchester Corporation had its own station, and they were going to build another large station on the outskirts of their area. Glasgow was a very similar case. Glasgow was one of those places where electrical enterprise had advanced at a very rapid rate indeed. He had visited the great generating station at Niagara before it was opened, and was acquainted with its progress. There they utilised the water-power with the intention of distributing it to places at a great distance; but as a matter of fact, a large town had grown up close to the station. In Buffalo city, 20 or 30 miles distant, they found they could generate the energy as cheaply with coal. He did not think the Niagara station could supply further than 30 miles at as cheap a rate. He thought there should be power to compulsorily purchase land for generating stations.

The CHAIRMAN: Do you look forward to a great increase in the use of electricity in the next few years?—Yes, and I think the progress made in this country has been too much discredited. The progress made in England is very great indeed. Progress with regard to electric tramways has been slow, and that is due to the clauses in the Tramways Act. With regard to electric lighting, I am not sure that we are not in advance of America.

Proceeding, WITNESS referred to the network of pipes of all sorts under many of the streets of London, and he thought the time would come when the Post Office would have to put itself officially in communication with the London County Council and the local authorities to see if they could come to some terms by which subways could be constructed for the mains.

Sir COURTENAY BOYLE, recalled, put in a letter received from Mr. Alexander Siemens with regard to the question of insulation in Germany.

Questioned by Mr. KIMBER as to the possibility of having a sliding scale for electric lighting companies as in the case of gas companies, WITNESS said the difficulty was to fix the initial price; but the Board of Trade hoped soon to introduce the sliding scale.

(*To be continued.*)

HIGH RESISTANCE INSULATION.*

By REGINALD A. FESSENDEN.

(*Concluded from page* 598.)

As mentioned, this author considered a simple case of Maxwell's general theory, and proved the above results by making actual measurements on condensers and resistances connected up so as to correspond to a simple case of a dielectric of high resistance with conducting particles in it. This paper should be read by all electricians, especially those concerned with cable work. I would like to speak of this subject more in detail, but for lack of time will only add that most of the conclusions in that paper have been confirmed by me, and that some which had been arrived at independently were seen to be in perfect agreement.

It is this absorption and the consequent losses which make glass useless as an insulator against high A.C. voltages. In some experiments made by Messrs. Stanley & Chesney which were shown me, the glass plates of the condenser, when on an A.C. voltage (though thick enough to have stood 10 times the D.C. voltage), after a few moments got hot, sparks could be seen passing inside the glass, and the plates finally broke down. Glass is not homogeneous, as it is made up of a number of substances, some much better conductors than others, and of different capacities, and all stirred together but not dissolved. This is shown by the care which has to be used in getting glass homogenous enough for optical purposes, it even having, as has been told me by Mr. Brashear, to be kept perfectly horizontal when annealing, as the heavier parts tend so much to sink down to the bottom, even when the glass is only plastic, that the only way to do is to keep the levels of different density parallel to the surface of the disc so that their effect on the light will be as equal as possible for all rays. Otherwise one side of the lens would be of heavy glass and the other light, while at present it is so arranged that one face is dense and the other light. Mica is much less objectionable, especially if its cracks are filled up and it is well dried. Paraffin when properly treated makes very good condensers. The old method of piling together pieces of paraffin paper and tinfoil and then pressing them, left much air and moisture inside. This produced large electrical absorption and gave large capacity. Messrs. Hutin & Le Blanc were the first to discover that good condensers could be made by heating such condensers till the moisture and air were expelled. Their results† showed that the specific inductive capacity of this more homogenous dielectric could be reduced from 8 to 2·5. I have myself found it come down as low as two. They then found that the same results could be obtained by heating the paper before making up the condenser. Since then, this method of forming condensers by heating them to expel moisture, air and acid has been used quite generally, with some modifications and improvements resulting in a shortening of the process.

It may be said as a general rule that the capacity of all substances showing absorption may be reduced by this treatment, if the heating be kept up long enough. A great many oils, for instance, are given high capacities, but I have found that in many cases this can be greatly reduced by this method, and that the slight remaining excess of K. over that called for by Maxwell's theory can be almost entirely removed by removing the free fatty acids, mucins, &c. Oils tested by me were olive, castor, linseed, and cottonseed. All these have very high insulation resistance and low specific capacity when so treated and purified, but they soon lose this again when exposed to air. It is evident, therefore, that the anomalous results obtained by Hopkinson and others were due, in some cases at least, to impure material, and such results must be considered as forming a strong proof of the correctness of Maxwell's theory.*

But when the substances are not themselves solid, but viscous, they must have a mechanical backing. For this pure cellulose is generally used. Pure cellulose contains some loosely combined moisture. Consequently it can exist in two states. Dried below 100° C. it decreases its specific inductive capacity very much, and has very high resistance and is flexible. Kept above 100° C. for any length of time it loses some of its combined water, has a much higher ohmic resistance, and its specific inductive capacity sinks to 1·9 or 2. It, however, becomes very brittle, and even though the temperature be only a few degrees above 100° C., it finally cannot be bent without breaking. (This brittleness must be carefully distinguished from the so-called rottenness which cotton fabrics get when dipped in linseed oil and dried. The fact that cotton tears easily in such a condition is due to the same cause as makes a wire mosquito netting tear when painted, *i.e.*, the fibres are stuck fast by the varnish and cannot help one another. This can be proven by removing the dried oil, when the fibre will be found to have nearly its original strength.) In this condition it is best suited for making condensers. The paraffin itself is greatly improved, as was pointed out by Hutin and Le Blanc, by heating to about 140° C. Three hours heating I have found satisfactory. The dried paper, immediately on removal from the oven, is plunged into the hot paraffin, so as to protect it from absorbing moisture. The condenser is then made up and boiled so as to remove the air, for several hours. This boiling method was described in a recent patent as a novelty, but it was used by Mr. Chesney at Pittsfield in 1891.

A condenser so made, if perfectly pure cellulose is used (perfectly pure paper is used in practice), and with pure paraffin, will stand 250 volts per thousandth of an inch when the dielectric is less than ·01 inch, and at a higher rate for greater thicknesses, when the effect of small defects in one sheet of paper is not so serious.

Practically the same remarks apply to the making of induction coils. Here, however, we meet with the great difficulty that the paraffin in cooling is sure to shrink, and will leave hollows inside. The way to get over this is to construct the coil so that when cooling the shrinkage will take place outside, just as if one were making a casting of some metal having great contraction. The coefficient of adhesion also should be less between the walls of the mould and paraffin than between the wire and paraffin; also the outside should never be let harden first, as then, of course, a hollow space is left inside. Another precaution is to expel all gases by heating the paraffin for some time above the temperature at which the coils are to be boiled. The coils should be boiled above 100° C. for some hours to drive off the loosely combined water. This destroys the mechanical strength of the cellulose, but as the whole coil forms a solid mass this is of no great consequence.

Silk should never be used where high insulation is required, as pure cellulose, dry and boiled in paraffin, is so much superior to it that there is no comparison. With pure cellulose, coils with only 1,700 feet of wire per inch of spark stand perfectly, *i.e.*, the spark may be five times longer than the coil. In ordinary use, coils having a spark length $3\frac{1}{2}$ times that of the coil have been run for long periods with no breakdowns.

As regards oil insulation for ordinary induction coils, the writer has not had sufficient practical experience. I believe, however, that very good results are obtained. With regard to the Thomson high frequency coil,† there is no question of the efficacy of oil there, especially with regard to ease of repair. As is well known, however, the oil and coil should always be heated above 110° C. for some time if the best results are to be obtained. A very curious increase of insu-

* Extract from a paper read before the American Institute of Electrical Engineers. From an incomplete advance proof.

† *La Lumiere Elec.*; July 25th, 1891.

* A rule connecting this effect with the sign of the Kerr's electrostatic optical effect has been given by the writer.—*Elec. World*, January 2nd, 1897.

† Popularly known as the Tesla coil, on account of his having brought it into prominence through his use of it in his lectures though it was invented and first described by Elihu Thomson.

lating power for high frequencies in oil has been noted by Elihu Thomson, who has suggested that it might be due to inertia of the molecules of oil. To test this, one of the writer's students, Mr. Bennet, constructed a two-phase high frequency electrostatic field. Though insulators placed in this rotated even when placed within a $\frac{1}{16}$th inch glass flask, the effect was found to be due to air currents, and when these were eliminated no movement was obtained, so that the cause of this effect is still unknown, and it is doubtful if true dielectric hysteresis has ever been observed.

So far as Mr. Chattock's experiments and the experience of the writer go, there is not a great deal of difference between the dielectric strength of different substances. It is probably related to the tensile strength. As mentioned previously, the writer* pointed out that there was strong evidence to show that the tensile strength of a substance was due to the mutual attraction of charges on the atoms, and that the observed values agreed well with the calculated and followed the same law. Some time later, Chattock,† in a very interesting and able paper, showed that, as the results of his experiments, the dielectric broke down when the slope of potential was great enough to pull apart atoms having charges of the same dimensions as the ionic charges. This was shown for gases, fluids, and solids, and forms a very interesting—and, I believe, independent—corroboration of the writer's electrostatic theory of cohesion. Consequently, the nearer the atoms are together, and the greater their rigidity, the greater also their dielectric strength.

Chattock's experiments give for solids and fluids :—

Substance.	Volts per cm. for breaking down.
Glass	919.000
Water	1,050.000
Oil	930.000

which agrees well with the theory.

From the above it will be seen that, if the materials are pure, and ohmic resistance is of not much importance, a compound having its molecules held together tightly will have a good dielectric strength for D.C. voltages.

This paper is already so long that I cannot touch in detail on the question of cables. There are also other papers in existence written by men better equipped for the task. I had intended saying something about what Siemens has called the "absurd craze for high insulation resistance," but the fact is now generally recognised, except by inexperienced engineers, that the best cables are those of medium ohmic resistance. I will only mention two methods which have occurred to me as feasible for certain purposes. One is based on the fact that the dielectric strength of air, as shown by the experiments of J. J. Thomson and Peace, increases very rapidly with the pressure, at 90 lbs. per square inch being equal to that of a good quality of rubber. A similar plan, though not requiring any very large pressure, is due to Mr. Westinghouse, who thought of employing it four or five years ago in Philadelphia. The second occurred to the writer on reading Elihu Thomson's article on the use of liquid air as an insulator. It is this: Since ice at only 12 below freezing has a specific resistance of over 1,000 meghoms, *i.e.*, as good as some brands of insulation, why not make the conductors hollow, lay them in a trench filled with water, pass cold brine through the pipes, use the brine for cooling houses, making ice, &c., and let the frozen water act as the insulator. A rough calculation shows that this is commercially feasible, even neglecting all sources of profit from the furnishing of the brine (*i.e.*, if it were used only for cooling the pipes). After making all allowance for friction of fluid, cost of power, &c., the balance comes at the right end, if the line is always fully loaded.

The question is sometimes raised, whether we can ever hope to have a non-inflammable substance which shall be elastic like India-rubber. The probable cause of the elasticity of rubber is known,‡ and it would seem as if there was no reason why such a substance should not be prepared. All we have to do is to coagulate one substance in the midst of another. In fact, we have at present in tetrametaphosphate of sodium such a substance, elastic as rubber, transparent and tough, and when pure, a good insulator. It would be an admirable material if it were not for the fact that the elasticity is due to water, and when this dries out it becomes brittle.

As regards an organic artificial rubber, I have very little doubt but that it will be made as soon as it is understood by chemists that its properties are due to structural and not chemical causes.

Armature windings.—The present methods of using mica leave little to be desired. The writer might mention, however, one novel method he used in a case where very heavy currents were to be carried. Asbestos and silicate of soda, as is well known, form a good coating, but is, however, poor mechanically. The armature bars were wrapped with asbestos string and then coated with the silicate. This made when dry an extremely firm covering which could only be removed with a hammer. Though at first a bank of 100 lamps could be lit up through the insulation, after a little running it dried out to quite a high figure and the machine did good service, at one time running several hours as I am informed on good authority, under such an overload that the carbon brushes were red hot.

In cases where cloth is to be treated, we have a very different question. There are two ways of using cloth, first, as a backing merely, by coating it on the surface with some substance which is supported by it, as plaster on lathing. Many substances work well in this situation, but the fact that little tubes of cellulose are very apt to stick up through the coating, as was pointed out to me by Mr. F. R. Upton many years ago, and that if moisture gets in at the edge it spreads all over, renders it not the best kind of insulation. Rubber is sometimes applied in this way to cotton tape, but though of very high resistance and insulation at first, it rapidly deteriorates. In general it should be said, that where a permanent result is desired, rubber should never be used unless kept in the dark, and out of contact with air. If these precautions be neglected, the life is very short. The other method is to saturate the whole cloth with some substance which will penetrate every crevice; but when this impregnating substance has solidified, it must continue to fill these crevices and capilliary tubes. For this reason no substance which is dissolved in anything else can be used. If, for instance, we try a varnish dissolved in alcohol, it will be found that the strength of the solution in the capillary tubes is much smaller than outside, for the same reason that sea water filtered through sand becomes fresh.* Consequently on drying these capillary spaces are not filled up and let water in. Therefore, unless we adopt the first method and plaster the insulator on thickly and deep enough so that it does not matter whether the support insulates or not, we must use melted solids or drying oils. Unfortunately but few solids which melt are *elastic*, since this elasticity is obtained by a structure which is destroyed by melting, and those solids which melt into thin liquids and remain *flexible* when solid do not preserve this property except within narrow limits of temperature, as can be easily tested by holding under a cold water tap and striking the specimen sharply. Soft paraffin can be used in some cases if the cellulose be well dried and thoroughly saturated. The asphalts cannot as a rule be used, as they never get sufficiently fluid on melting. There is, however, one notable exception: uintaite or, as it is commercially called, gilsonite. This substance I found many years ago had the peculiar property that, when melted, like paraffin or oil, it will pass into the the pores of cellulose or cloth. Having a very high melting point, nearly 300° if I remember, and mixing perfectly with paraffin in all proportions, it gives mixtures which are admirably adapted for induction coil work as these compounds can be made to have high melting points and to penetrate a coil thoroughly. I also, some years later, in 1891, used this material in combination with linseed oil for transformers, the process at first proposed being boiling in vacuum, but it was found that even without this saturation was complete. I understand that this method is still used, though modified in form, by the company for which I first devised it. Of the drying oils, with the exception of some foreign oils as Chinese wood oil, and an African oil whose name I cannot recollect or ascertain, linseed and the drying nut oils are the best. Linseed oil has the remarkable property of expanding on drying. This enables it to fill up all pores. Its durability is evinced by the good condition of old oil paintings. The varnishes crack and go, but the oil

* J. J. Thomson, "App. on Dyn. to Phys. and Chem.," p. 190.

remains. Its insulation is not injured up to very high temperatures at which shellac, rubber, &c., would be worthless. This material was used a great deal by the Edison company in its early days, but it often broke down. The trouble was traced to the lead drier, and after many experiments Mr. Marshall, who had charge of this work, finally settled upon the use of pure raw oil. This gave excellent results, and was long used, but took some time to dry, and the writer finally, after many tests, found that borate of manganese drier got rid of the trouble, while, as is well known, it gives a very quick drying varnish. This was used by the United States Company in Newark on their machines, with the result that in 1890, after use for a year, the former reported only two armatures so treated as returned for repair (they were injured by lightning), and no fields. This material was also used by the Stanley Company for transformers. Another advantage of this borated oil is, that it always retains a slight stickiness, and so gives a good joint when wrapping around wires, &c. Many substances so used are not sticky, and let moisture in through the joints. Where a smooth surface is required, it is readily obtained by dusting on a little talc, a method first suggested, I believe, by Mr. Edison. It can also be given a coat of Japan on the outside. Varnish gums should never be used with linseed oil, as they are brittle, and the dried oil is only just flexible enough. Consequently, when the oil has dried the resultant varnish is always very brittle. A temporary elasticity is given at first by the fact that when the solvent has dried off the oil is still fluid and undried, and as the varnish gum keeps the air from getting at it rapidly, it sometimes remain flexible for a year. Such mixtures also crack when cold.

Sample *c* is a specimen of borated oil saturated cloth, which is now between eight and nine years old. It will be noted that it is still fresh and flexible, and a recent dielectric strength test showed up very high, 7,000 volts if I recollect. The pure raw oil is boiled at about 200° with ½ per cent. of borate of manganese for several hours till it begins to be thick.

Non-inflammable materials can be made, as I have pointed out elsewhere, by taking out the hydrogen atoms of hydrocarbons and substituting chlorine. Even paraffin can be thus treated if kept warm, and first turns to a fluid and then to a solid. At one time it seemed as if this process might be valuable, but the use of enclosed conduits has done away with the greatest source of danger from fire.

I will conclude by describing a couple of devices which I have found useful in preventing insulation from being spoiled. Soldering acid, as commonly used is a solution of chloride of zinc. If this falls on cellulose it turns it to a paste. It never evaporates and always takes up moisture from the air, and will gradually eat its way through quite a thickness of insulation. Whether it is acid or neutral makes no difference so far as its action on the insulation is concerned, though the neutral solution does not corrode the wire. Resin has the disadvantage that it is not a fluid, and is clumsy to handle. I have found that by shaking up powdered resin in very strong ammonia, an ammonia soap is produced which works well in most cases. The ammonia dissolves the copper oxide and evaporates afterwards, leaving the powdered resin which is an insulator.

Apparatus can be protected from overheating by putting in the apparatus a small glass tube filled with carnauba wax. This melts near the danger point, but remains quite hard up till then, so that by imbedding a spring and contact in the wax, when the apparatus gets too warm the wax gives, and the spring expanding causes a short circuit, which blows the fuse.

The largeness of the subject must be my excuse for the fragmentary nature of this paper. After I had begun it I found I had made a mistake; what I should have undertaken was to write a book. I trust, however, that some of the points I have developed may prove of interest.

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. Thompson & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*

8,988. "Improvements in electrodes for accumulators." C. Alker and P. Mennesseier. Dated April 18th.

9,002. "Improvements in, or connected with, apparatus for the manufacture of potassium chlorate or sodium chlorate by electrolysis." J. Brock and The United Alkali Company, Limited. Dated April 18th.

9,070. "Improvements in contact shoes for electric railways." W. M. Brown. Dated April 19th. (*Complete.*)

9,071. "Improvements in, and relating to, telegraph and like cables." J. A. L. Desblove. Dated April 19th.

9,077. "Improvements in enclosed arc lamps." G. Thomas-Davies. Dated April 19th.

9,091. "An improved connector for electric wires and cables." T. E. Taylor, jun., and J. Collings. Dated April 19th.

9,105. "Improvements in apparatus to be used in connection with the electro-deposition of metals." F. Greenfield. Dated April 20th.

9,122. "Improvements in, and connected with, line selectors for telephones." H. Oppenheimer. Dated April 20th.

9,154. "Improvements in electric lamps." T. S. Hill and Peto and Radford, Limited. Dated April 20th. (*Complete.*)

9,178. "Improvements in electro-motors." J. T. Robson, C. H. Marsden, and H. W. Headland. Dated April 20th.

9,197. "Improvements in, and relating to, telegraphic transmitting apparatus." F. G. Creed Dated April 21st.

9,213. "Improvements in electrical heating and cooking." W. B. Spikins and A. H. Mayes. Dated April 21st.

9,218. "Improvements in secondary batteries." G. E. B. Pritchett, T. W. Pritchett, and A. G. Gold. Dated April 21st.

9,237. "Improvements in holders for high tension incandescent electric lamps." G. E. Heyl-Dia. Dated April 21st.

9,292. "Improvements in electrical igniters to be used with gas or oil engines, or for similar purposes." W. Baines, Jun. Dated April 22nd.

9,299. "Improvements in or relating to overhead trolley wires for electric traction overhead electric cables or other wires." R. Hacking. Dated April 22nd.

9,317. "Improvements in electric igniting devices for cycle lamps." G. M. Bauer and F. Kriegner. Dated April 22nd.

9,330. "Improvements in controllers for electric motors." R. Belfield. (The Westinghouse Electric and Manufacturing Company, United States.) Dated April 22nd.

9,339. "Improvements in electrical switching apparatus." H. Edmunds. Dated April 22nd.

9,340. "Improvements in electric safety fuses or cut-outs." Verityss, Ltd., and L. J. Steele. Dated April 22nd.

9,380. "Improvements in and relating to alarm clocks and electrical alarms." H. G. Campbell. Dated April 23rd.

9,394. "A process for electric heating and furnace for realising same." A. Roufaut. Dated April 23rd.

9,425. "Improvements in or relating to electrical cut-outs." J. W. Manley. Dated April 23rd.

9,436. "Improved means for electrically heating second-class electric conductors serving as incandescence bodies for imparting to them the requisite conducting power." M. Deri. Dated April 23rd. (*Complete.*)

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. (*in stamps*).

1897.

19,230. "Improvements in a system for the electrical protection of safes." I. Freed. Dated August 19th, 1897. This relates to a protection system comprising of a closed electric circuit; the safe forming a component part of the circuit. On the interruption of the circuit there is a means for sounding an alarm bell. There is an electromagnet and its armature forming an integral part of the circuit, but arranged outside the safe. There is also a structure provided with a recess; with lugs fixed in the walls of the recess. There are a series of spring pawls fixed to the safe and adapted to engage in the lugs and lock the safe in the recess. 9 claims.

19,518. "Improvements in electric arc lamps." T. Spencer. Dated August 24th, 1897. This relates to an arc lamp adapted to be operated by an alternating current; and consists of a combination of opposed solid carbon electrodes with an enclosure for their proximal ends. There is a choking coil in electric circuit with the electrodes, and an automatically movable core for the choking coil. The core is connected with one of the electrodes so that a reciprocatory movement of the core may be imparted to the electrode. 1 claim.

18,934. "Improvements in automatic electric alarms." P. V. Vandevelde. Dated August 16th, 1897. This relates to an alarm device for use in ordinary window sashes provided with counter balance weights. Below the usual grooved pulley are placed two spring arms fixed to the casement one above the other. They are insulated from one another and connected with a battery. The top one is longer than the other and comes in contact with the weight when the sash is down. As soon as the sash is raised the weight is lowered and the end of the spring arms are so arranged as to spring together; which completes the circuit and operates the alarm. 2 claims.

PARLIAMENTARY ELECTRICAL ENERGY COMMITTEE.

IT seems to have been the general opinion of counsel and of all others engaged in the Parliamentary Committee, whose proceedings we have reported at considerable length, that the matter was carried through at a great rate, and that the issues were much confused. It is pretty clear that there has not been time to sift the whole matter, and that whatever the report of the Committee, it will scarcely be final. If the Committee are prompt in their report, and there is time to draft a Bill embodying their recommendations and get it through the House this session, enough may be done to relieve the almost absolute block which there is at present; but it is perfectly evident that there are a number of other questions which are rapidly ripening for solution, and it is greatly to be desired that the electrical industry, as a whole, should begin to consider this carefully and organise themselves with a view to getting their case more strongly and authoritatively placed before Parliament than has been possible on the present occasion, mainly because of the short notice and rapidity with which the matter has been carried through. We think it is very desirable to urge the importance of the recommendations of the Committee being given effect to by Parliament this session, as another year's block, whatever is done in the end, would leave us another 12 months behind our foreign rivals.

We are hopeful from what was gathered of the general tone of the members of the Committee and the evidence, that, at any rate, some of the discouragement to which private enterprises are subjected at present may be removed. We doubt if very much will be done directly to this end in the Committee's report, in fact, we do not know whether from the nature of the reference to them they can do much, but the evidence was strong in favour of the old political economic dictum that officials favour officials, and that although the Board of Trade were supposed to have a discretion to give private enterprises at any rate a fair chance, yet that in practice their powers had so been used as to put a complete stopper on it. Sir Courtenay Boyle practically acknowledged this himself, and we think most people will agree that it is so, and to a greater extent than appears on the surface, since a certain number of companies did get through in the earlier stages, and when private individuals felt less hopeless than they do now of carrying out any enterprise. We believe it will be found to be a fact that notwithstanding the enormous increase of electrical enterprises in other countries, the *rate of increase* in this country is not progressing. In fact, we are not sure if apart from the manufactures carried out to supply Corporations and what may be called purely private work it is not diminishing, although both in Germany and America it is progressing by leaps and bounds.

In connection with this we might refer to the reports from Berlin in the *Financial News*, and the large space which is

D

given very frequently to particulars of electrical enterprises, whereas in the same paper the reports on English enterprises are at most three or four lines, and these deal almost entirely with London companies.

Again, we would point out the unfairness of the matter to those engaged in the electrical industry. Of course, now private enterprise is pretty well snuffed out for ordinary undertakings; but, at the same time, it is true that the teaching of the local authorities, the bringing forward of facts and new ideas, and their education, has almost entirely been done by private individuals, often at great expense both of money and time. Although such men deserve well of the nation, and it is on the labours of such men in other departments that the greatness of England has been built; in the case of the electrical industry, owing to the state of the law, and the action of municipalities, they have not only received no reward or encouragement, but have been pushed aside often with contempt, and left to bear heavy loss and discouragement.

If our rivals in America and Germany were pursuing the same course as ourselves the matter would not be so serious, because we and our trade rivals would be in the same boat, and one would have no advantage over another; but that is not so, and we think it is acknowledged on all hands that both our great commercial rivals have got a considerable start of us in this matter, and the encouragement there is for them to proceed with further developments will undoubtedly enable them to keep ahead of us, and probably to increase their lead, unless strong measures are taken to put the members of electrical industries in this country in at least as favourable a position for the development of enterprises as are our industrial rivals.

We hail with satisfaction the activity which has characterised local bodies for some years; at the same time we cannot help thinking that often, not being very well instructed, there is far too great a tendency amongst them to conclude that what is sauce for the goose is sauce for the gander in all cases, and that because such towns as Manchester, Edinburgh, and some other municipalities of large area, and where commercial intelligence of a high order can be secured on the Town Council, have done ostensibly well, that consequently it follows that comparatively small towns of a different character, and where the majority of the members cannot usually have the same business experience, can produce similar results.

The Candle-Power of Arc Lamps.

In a recent issue of the *Electrical Review* of New York, Mr. Marks, of enclosed arc lamp fame, replied to the question of a correspondent who asked, "What is the candle-power of an arc lamp using 45 volts and 10 amperes?" by detailing the reasons which make it impossible to answer this query with any degree of accuracy. Although it has been common knowledge for many years that any statement of the candle-power of an arc lamp was certain to be misleading if unaccompanied by full details of the conditions under which the test was made, yet it is probable that the extent of the possible error is not so generally known, and the figures given by Mr. Marks will therefore be of interest. It is said that there are five different candle-power values which are used at various times, viz.: (1) Nominal candle-power, the value of which, according to the definition adopted by the National Electric Light Association, is 2,000 for a 450-watt lamp. (2) Horizontal candle-power which has been given by different experimenters at figures varying from 227 to 456. (3) Maximum candle-power which has been given at figures varying from 1,080 to 2,000. (4) Mean spherical candle-power which has been given at figures varying from 425 to 653. (5) Mean hemi-spherical candle-power below the horizontal plane passing through the arc, which Mr. Marks gives as 600. But if it is decided that results shall be given in one particular value of the five named above, say, for example, in mean spherical candle-power, and if full information is given concerning the globes or reflectors used and whether the test is made in a dark room or at the place where the lamp is in service, there still remain variations due to quality and size of carbons, shape of the carbon points, and personal errors of observation. Mr. Marks says that it has been found that the substitution for one carbon of another of different quality has made as much as 80 per cent. difference in the mean spherical candle-power, and that with carbons of the same quality there may be a difference of 30 per cent. in the candle-power according to whether the carbon is $\frac{7}{16}$-inch or $\frac{5}{8}$-inch diameter. With regard to personal error, a test is quoted where with 10 observers a variation of about 13 per cent. was found between the highest and lowest results obtained; and we are finally reminded that there are three important standard candles which may be referred to, viz, English, German, and French, and that there is a difference of about 15 per cent. between the values of the first and last named. After reading the article in question, it is strongly borne in on us that the only safe answer to such a general question as that of our contemporary's correspondent is, that the candle-power can best be represented by x, as tests can be quoted to show that it has any value between about 200 and 2,000 according to the conditions of test; and that in comparing the efficiency of arc and incandescent lamps for lighting purposes, it is necessary to reckon on 1 to $1\frac{1}{2}$ watts per candle for an arc lamp instead of on the lower figures which are often used.

Rayleigh on Stokes.

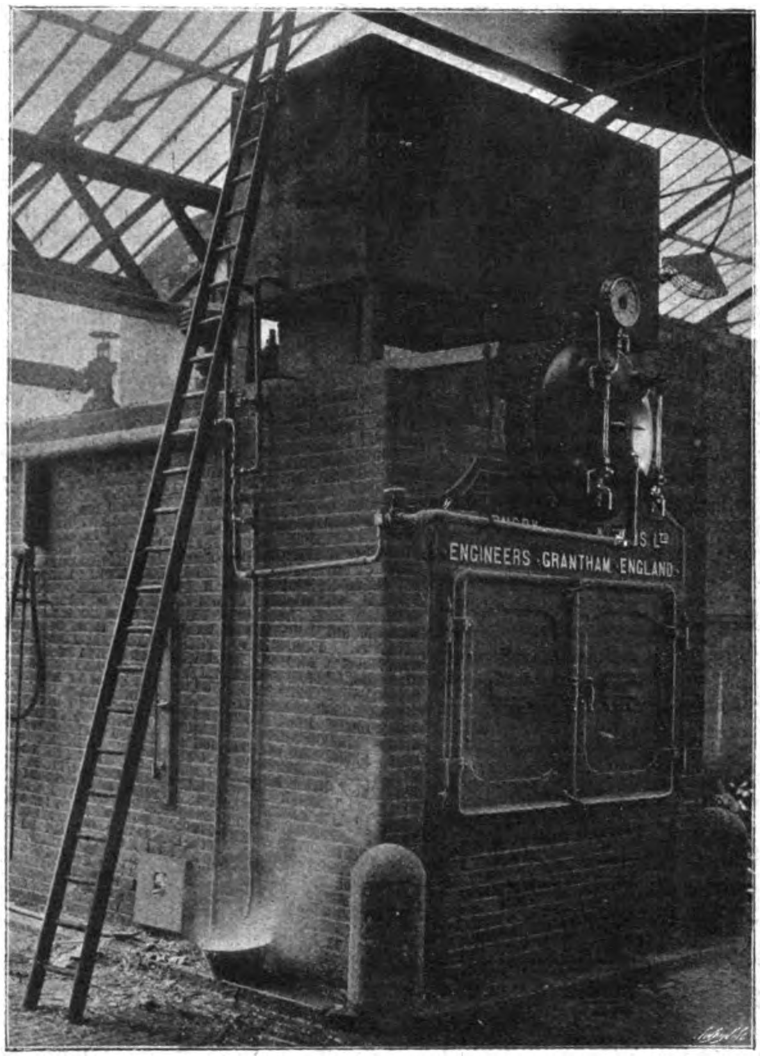
Sir G. Stokes, about two years ago, suggested a theory of the Röntgen rays, according to which the Röntgen rays were regarded as aperiodic electro-magnetic waves caused by the impact against the anti-cathode of the charged particles in the cathode stream. This theory has recently been developed by J. J. Thomson (*Phil. Mag.*, Vol. 45, p. 172, 1898), and has come much into favour with other authorities. In *Nature*, April 28th, however, Lord Rayleigh raises a protest against the acceptance of this theory. He says it has certainly much to recommend it, but he cannot see that it carries with it some of the consequences which have been deduced as to the distinction between Röntgen rays and ordinary luminous and non-luminous radiation. The conclusions of its supporters "that the Röntgen rays are not waves of very short length, but impulses," surprise Lord Rayleigh. From the fact of their being highly condensed impulses, he would conclude, on the contrary, that they *are* waves of short wave length. He asks what becomes of Fourier's theorem and its assertion that *any* disturbance may be analysed into regular waves? The view that the vibrations of ordinary light are regular, and thus distinguished from disturbances made up of impulses, he says, is an exploded idea, in the theory of light. A curve representative of white light, if it were drawn on paper, would show no sequence of similar waves. Rayleigh favours the view that Röntgen rays differ from ordinary light only in the shortness of their waves.

THE ST. PANCRAS DESTRUCTOR WORKS.

WE illustrate below a side view of the Hornsby water-tube boiler which has been fitted up at the St. Pancras Vestry destructor works, and is fired by the waste gases from the destructor.

The rating of the boiler, if fired by coal, is 118 H.P. (1 H.P. = 30 lbs. of water evaporated per hour) working pressure 120 lbs. per square inch, number of tubes 59 (seven deep, three rows of nine wide and four rows of eight wide), 18 feet long and 4 inches diameter. The steam drum is 39 inches diameter × 28 feet 10 inches long, and is provided with a patent separator to ensure dry steam; it is fixed over the uptake tube from the front header. The headers are provided with a hand-hole opposite each tube, and each hand-hole is provided with a mild steel internal safety cover. The mountings consist of one deadweight safety valve, high steam and low water, with whistle alarm; one 2-inch deadweight safety valve; one steam stop valve; one steam gauge dial 10 inches diameter; one check feed valve $1\frac{1}{2}$ inch diameter; one blow-off valve 2 inches diameter. The boiler is made throughout of mild steel, no cast-iron or cast-steel being used in its construction.

We are informed that the boiler has done excellent work and given every satisfaction.



THE ST. PANCRAS BOILER.

THE TEMPERATURE OF INCANDESCENCE LAMPS.*

I HAVE already described† a purely electrical method of measuring the temperature of incandescence lamps, and more generally, of any radiating body whatever. This method consists in studying: (1) the variation in the resistance of the lamp as a function of the difference of potential at the terminals; (2) the variation, as a function of the time, in the resistance of a lamp which is cooling. From this we can easily deduce the curve of the watts radiated as a function of the time, and consequently, the total number of joules or small calories given off by the lamp. The filament is then weighed, and from M. Violle's formula:—

$$Q = \cdot 355\, t + \cdot 00006\, t^2$$

we deduce the temperature t (assuming that the filament is made of pure carbon).

This method was applied, under my directions, by Messrs. Gindre and Fréauff-Ozeune, then pupils at the Ecole Supériure d'Electricité ‡; the first measurements were taken with the aid of an amperemeter and a voltmeter and presented no difficulty; the subsequent ones were more difficult; they were carried out in the following manner:—

A special interrupter enables the following operations to be performed:—

1. At the time zero, the current of the lamp is broken.
2. Immediately after, the lamp is introduced into an auxiliary circuit including an accumulator and a resistance box.
3. At the time t, an instantaneous contact brings the two terminals of the lamp into connection with the plates of a condenser.
4. This condenser is discharged through a ballistic galvanometer. These various operations are executed by a slide which moves in a direction parallel to itself between two grooves; the intervals of time are measured by a tuning fork which inscribes its vibrations on smoked paper; it is evident that at these high temperatures the cooling is very rapid, and that it is necessary to be able to measure accurately fractions of a second. A simple calculation then enables us to find the resistance of the lamp at any given moment.

The experiments were carried out on four lamps, A, B, C, D, of 65 volts and 10 candles. I will call t the temperature, R_o the resistance of the lamp to the ordinary temperature, R_t its resistance to $t°$, p the weight of the filament expressed in milligrammes, E the tension at the terminals. These are the results obtained:—

Lamps.	E	p	R_o	$\frac{R_t}{R_o}$	t
A	65	6·3	175	·53	1,720°
B	65	5·35	170	·54	1,610°
C	65	5·2	170	·52	1,630°
D	65	4·8	170	·53	1,620°

We see that the results relating to the lamps B, C, D are very similar; the lamp A, for some reason or other, gives a somewhat higher temperature.

However this may be, the above results are of some importance when we consider the differences in the figures of the various writers that have treated this subject. H. F.

* Note presented to the Académie des Sciences, March 7th, 1898.
† See *L'Electricien*, Vol. xii., p. 323.
‡ The experiments were made at the Central Electrical Laboratory.

Weber, in fact, mentions these temperatures as hardly exceeding 1,300°, whereas M. le Chatelier gives 1,800°.* It will be seen that our results more nearly approximate to the latter estimate, especially as we have reason to think that our lamps were less *over-run* than those of M. le Chatelier; these are the variations of resistance given by him:

t	$\frac{R_t}{R_0}$
15°	1·00
700°	·75
1,000°	·66
1,400°	·57
1,800°	·49
2,100°	·44

At the temperature of normal working, the ratio $\frac{R_t}{R_0}$ was ·49 for M. le Chatelier's lamps, whereas this same ratio attained to ·53 in our experiments; now, at this value ·53 corresponds exactly to the temperature 1,600° in M. le Chatelier's table.

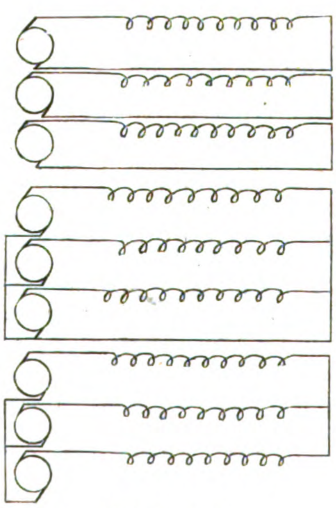
The principal cause of error in the above experiments lies in the light weight of the filament; it would be easy to remedy this by working with low voltage lamps. We can, in fact, easily show that, with an equal lighting power the weight of the filament of a lamp varies in inverse proportion to the two-third power of the difference of potential at the terminals.

From the above experiments we can deduce curves of the variation of the total radiation as a function of the temperature, but this question is too important to be entered upon here.

THREE-PHASE MACHINERY.

The *Western Electrician* for April 9th, 1898, contains an interesting article on three-phase machinery by W. M. Venable, in which some of the principles underlying three-phase working are expressly stated in a very simple manner for the benefit of those who are not able to make a thorough study of the subject and yet who require a good general knowledge of it.

If three alternating-current generators, supplying three separate circuits as in fig. 1, are connected together at one terminal only, the operation of the machine will not be affected. Such a connection merely brings the three terminals to a common potential, and does not affect the difference of potential between the two terminals of any one



Figs. 1, 2, 3.

machine. There will, therefore, be but little effect on the operation of the machines if a common wire is run for all, as in fig. 2.

If now we can arrange the circuits and construct the dynamos so that there will never be any current in the common return wire, we can dispense with that wire altogether. This condition is satisfied when the currents in the three remaining wires are 120° apart in phase and equal in intensity.

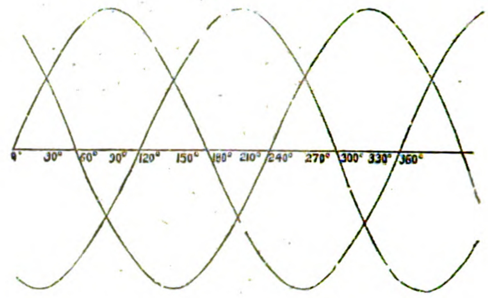


Fig. 4.—Sine Curves of Three-Phase Circuit.

Fig. 4 represents three equal sine curves 120° apart, and shows that the algebraic sum of the ordinates at any instant is zero. We have, then, the arrangement shown in fig. 3, and if the loads in the three branches are equal, three line wires only are needed. The easiest way to keep the machines 120° apart in phase is to combine the three machines in one, that is, to put three windings on one armature. Such machines are called three-phase alternators. A simple one can be made of a Thomson-Houston arc dynamo by bringing the terminal wires to collector rings instead of to the three commutator segments. The fields have to be separately excited.

Fig. 5 is a diagram of such a winding.

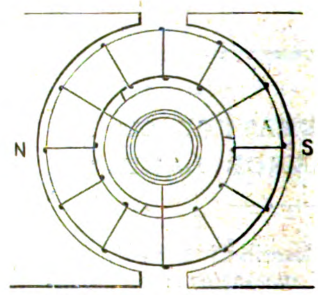

Fig. 5.—Three Phase Winding for Two-Pole Machine.

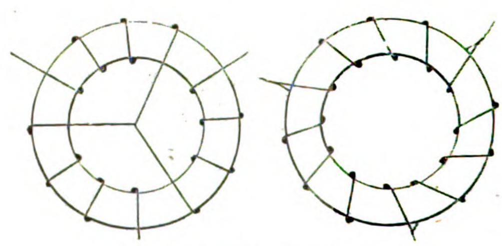
The number of poles can, of course, be increased, just as in an ordinary alternator, increasing the frequency of alternations.

There are two ways of connecting the armature coils of a three-phase alternator. One of these, known as the star connection, is shown in fig. 6; the other, known as the mesh winding, is represented in fig. 7.



Figs. 6 and 7.

One of the great advantages of three-phase working over single-phase systems lies in the fact that the energy transmitted can readily be used either for lighting purposes or for motive power. Three-phase induction motors are, as is well known, self-starting under a very considerable load, and are as simple, reliable, and as easily controlled as the continuous current motor. The induction motor is superior to the continuous current motor, in that its secondary winding is short circuited, and it is entirely devoid of commutator, collector rings, or any rubbing contact.

* *Journal de Physique*, 2nd series, Vol. i., p. 203.

Those readers who have not the time to study the subject deeply, will be able to form some idea from the above of the nature of the generation and distribution of electrical energy by means of tri-phase currents. There is novelty and great simplicity in the method of showing how it is necessary to use only three wires in three-phase distribution systems.

THE RANGE-FINDER FOR DETERMINING THE DISTANCE OF A HOSTILE SHIP OR FORT.*

The accuracy of modern rifled guns is one of the wonders of engineering. Two experimental shots fired a few years ago at the same elevation from the same gun fell within 30 yards of each other, after traversing a distance of 12 miles. If a modern rifle is laid upon the target, with proper elevation and allowance for windage, it is safe to say the shot will find the mark.

The correct elevation of the gun can only be determined if the distance of the target is known, and the exact determination of the distance of a moving object is a problem that has worried the gunner ever since the day when round shot was first thrown from the sides of the wooden fighting ship.

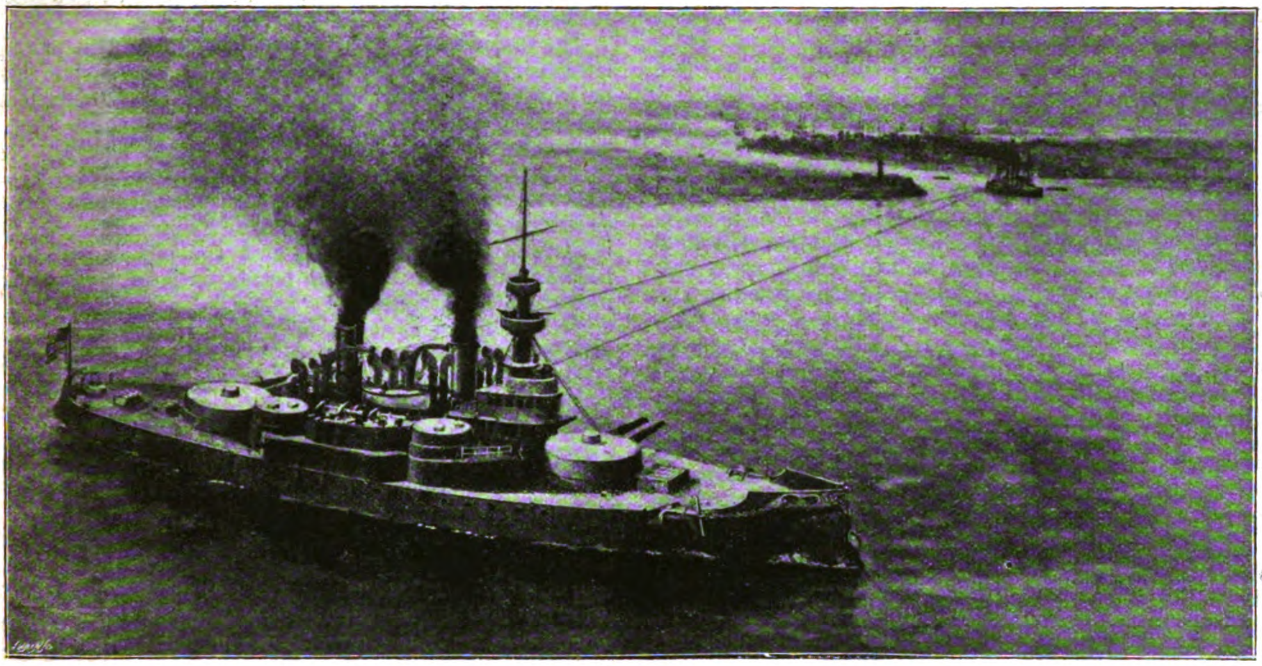
In the early days, the determination of the range was a matter of guesswork. The gunner assumed a distance, elevated his gun accordingly and watched the course of the shot. If it fell short, he increased the elevation, and if it passed over, he decreased it.

This was all very well in a day when the guns were too feeble to do much execution, except at close range, and a few dozen shots thrown away made little impression upon a ship's magazines. With the advent of modern ordnance, however, with its 60-ton guns and costly charges, the necessity of accurate fire became imperative, and ordnance experts set about devising some scientific method of finding the range at sea. The earliest and best known device of the kind was the invention of Lieut. Fiske, of the United States Navy, which has been installed on many of our ships and is widely in use in the various navies of the world.

The Fiske range-finder is based upon the well-known principles of land surveying with the transit and engineer's chain. If a surveying party came to a broad river whose width has to be determined, a base line is measured along the bank, and the angles which this line makes with a mark on the opposite bank are measured by the transit. Then, knowing the length of the base line and the two angles, the distance across the river can be determined by trigonometry.

Applying this to the range-finder, a base line is carefully measured between two points near opposite ends of the ship, and over each point a range-finder, answering to the engineer's transit, is permanently set up. If the telescopes of the two finders are simultaneously converged upon the same point on a distant object (ship, fortress, or city), the observers will be in possession of the trigonometrical data necessary to compute the distance, namely, the base and the two base angles.

In the din, hurry, and slaughter of a sea fight, however, it would be difficult to make the necessary calculations, as the distance between the ships, and, therefore, the observed angles, keeps changing, and in order to make the determination of the distance automatic, Lieut. Fiske placed his telescopes in the circuit of a Wheatstone bridge and caused their change of position to record the distance of the object on the graduated scale of a delicate galvanometer. All that was now necessary was for the observers at the two range-finders to keep the cross-hairs of the telescope upon the same point of the ship, and the electric current translated (as it were) the angles into distances and recorded them by



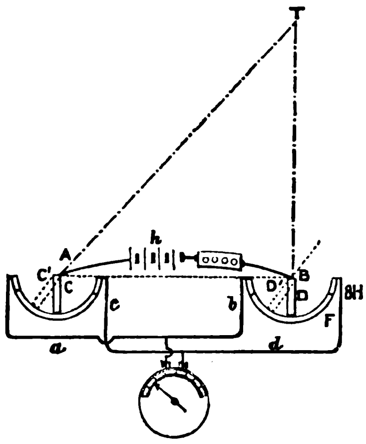
the movement of a needle over an arc graduated into hundreds and thousands of yards.

The above illustration will make the operation of this most ingenious instrument clear to the reader. It represents the *Indiana* about to open fire upon a hostile

* *Scientific American.*

ship. The converging lines are drawn from two range-finders, which are placed in elevated positions above either end of the superstructure deck. These finders are permanent fixtures, and the distance between them is accurately known. The smaller cuts show a range-finder and a diagram of the telescopes and the electrical connections.

The range-finder consists of a powerful telescope, which is



mounted on a standard and is capable of horizontal rotation above a graduated disc. Upon the disc, and extending an equal distance on each side of the zero point on the graduation, is a metallic contact arc. Fixed to the telescope standards is a contact strip, which rotates with the telescope and slides over the contact arcs. In the diagram A and B represent the centres of the discs on two range-finders, and C and D the arms that carry the telescopes and contact strips, which are shown sliding in contact with their arcs. The electric current from the battery, *h*, passes through the centres or pivots, A and B, and then into the arcs. From the right-hand arc it circulates in the wires, *b* and *d*, from the left-hand arc in the wires, *a* and *c*, and traverses the galvanometer.

When the two telescopes are parallel, the equilibrium of the Wheatstone bridge is complete, and consequently the needle of the galvanometer shows no deflection. This equilibrium occurs, moreover, whatever be the position of the telescopes on the dial, provided that they are perfectly parallel. But if the telescope, C, for example, be turned until it is in the position, C′, the parallelism being destroyed, and, along with it, the equilibrium of the two parts of the bridge, the needle of the galvanometer will be deflected. This deflection will increase in proportion to the length of the arc traversed by the telescope.

But since the arc, C C′, is proportional to the angle at A, which is equal to the angle at T, it follows that the deflection of the galvanometer will be proportional to the angle at T, or to the distance, A T. Hence, by graduating it in hundreds and thousands of yards, the distance of the ship or fort, T, may be read directly from the galvanometer. One of these galvanometers is placed in the conning tower and one at each of the principal gun stations.

It will be seen from the illustration that the operator, on applying his eye to the telescope, has opposite to his mouth a telephone transmitter, a receiver being clamped to his ear. By this means the two operators are kept in constant communication and the errors are avoided that would be caused by the reading of a deflection produced before one or other of the telescopes is well directed toward the point to be observed.

[More complete descriptions of the Fiske range finder can be seen in back issues of the Review.]

Personal.—We understand that Mr. Fred. J. Satchwell has resigned his position as manager to Messrs. Mackey and Mackey, electric lamp makers, Bermondsey, having been appointed superintendent in Mr. Hiram S. Maxim's electrical laboratory.

CARBONISATION OF FILAMENTS BY ELECTRICITY.

By Legh S. Powell.

The idea of carbonising filaments by electricity, in lieu of the common furnace method, must have occurred to many. It was widely reported some 10 or 12 years ago that the remarkable "adamant" filaments, introduced by Woodhouse and Rawson, had been subjected to intense heat by electricity, but no details of the process employed were ever noised about, or reached the ears of the writer; and it is believed that at the present time the carbonisation of filaments by means of electricity has not been practically adopted. As the subject is not without interest or economic possibilities, it has occurred to the writer to be worth while putting on record an electric method he devised for this purpose about five years ago, and a few particulars of certain rough and superficial experiments which were made at the time at a Continental lamp factory to test its practicability. It is hoped that some incandescent lamp experts, who care to test the plan further, and who are able to bring together the means and conditions needed for the investigation, will succeed in bringing this process, or one allied to it, to a successful issue.

The features of the method in question and the principles involved, are very simple and obvious. The carbon blocks on which the cellulose threads are wound are conductors of electricity, and the plumbago powder in which they are packed is likewise a conductor. If a pile of blocks be therefore made with a layer of plumbago powder between each, and the whole be surrounded with suitable non-heat and electricity-conducting materials, whilst a current of electricity is made to pass, it is evident that the blocks will become heated, and grow hotter and hotter, until in time the filaments will be carbonised or "baked."

To bake filaments successfully by this method, it is naturally necessary to attend to several conditions. It is obviously of prime importance that the heterogeneous conductor be encased in insulating material of the best quality, and arranged in the most suitable manner. It is equally necessary to exclude the air, so as to prevent the burning of the filaments. Other considerations of more or less importance are: facility in packing and unpacking the containing vessel, the construction of the terminal conductors, the manner of applying the current, the duration of the operation, and the final cooling of the blocks.

As already intimated, the experiments that were made were in the nature of mere trials rather than a serious and persistent attempt to thoroughly ascertain the economic practicability of the method. Two experiments only were made; and as the notes taken of the dimensions, times, amperes, &c., were far from complete, and also by reason of the superficial nature of the trials, it is not proposed to describe them in detail. Suffice it to say that in the first experiment two parallel brick troughs were constructed on a brick platform covered with a layer of slag wool. The troughs, which were about a metre long, were packed with wound blocks, plumbago powder being sprinkled between each space. The current entered one trough by means of a stout terminal plate of carbon, flowed to the end, then across to the other trough by a long slab of carbon, and so on to the other terminal. The upper surface of the troughs was covered by slabs of earthenware, and the whole was surrounded with a thick coat of slag wool.

The current which was available for the operation had a pressure of 110 volts, and this factor was largely responsible for the arrangement of the furnace in manner described. The resistance cold was a little over 2 ohms, and the current at the start was 50 amperes. In an hour or so the current had risen to 150 amperes, when it was lowered to 50 amperes again by introducing an external resistance. At the reduced pressure the resistance of the circuit continued to decrease, and the current once more rose to 150 amperes.

On examining the filaments at the end of the operation they were found to be brittle and useless, a circumstance which was probably due to burning by access of air during cooling, to hasten which a considerable quantity of slag wool had been removed.

In the second experiment the length of the row of blocks was increased to about 3 metres in order more nearly to suit the current pressure; and instead of forming a simple  the course ran thus . To more effectually displace the air, a layer of plumbago powder, sprinkled with paraffin, was spread along the bottom of the troughs before charging them with the blocks. In this experiment the plumbago powder was more tightly compressed than in the previous one, the resistance cold being 3·8 ohms. For the purpose of raising the temperature more slowly at the commencement, an external resistance was included in the circuit, and the current adjusted to about 18 or 19 amperes. Instead of the resistance falling from the start, as in the previous experiment, it had a tendency to rise during about five hours. This increase, which amounted at the maximum point to about 25 per cent., may possibly have been due to the presence of the paraffin. By gradually cutting out the resistance, the current was caused to rise slowly to 25 amperes. In 10 hours from the start the current was only 30 amperes, in 12 hours it was 35 amperes, in 14 hours 55 amperes, and in 17 hours it had reached 65 amperes. The circuit was here interrupted for the night, but was again closed next day, after a lapse of 6½ hours, the current starting at 27 amperes. In six hours' time it once more attained 65 amperes. It is believed that the current was stopped soon after this, but the notes taken are not specific on the point.

The majority of the filaments obtained from this second operation were satisfactory in every respect, their flexibility and "colour" being good, whilst their resistance cold remained practically steady both before and after raising to incandescence in an inert gas.

The problem of baking filaments by electricity was allowed to drop, not because it was anticipated that the process could not be made to give satisfactory results, but principally because it was not considered to be worth while to arrange for a current of lower pressure and larger quantity to suit other and more convenient forms of apparatus, and also because it was supposed, by some, that the electric method would not prove to be more economical, or possess any striking advantage over the ordinary furnace plan. Without, however, ascertaining a good deal more thoroughly what degree of perfection can be attained, the data wherewith to form a sound judgment as to cost, &c., are not forthcoming.

To describe in detail the best manner of proceeding in order to construct suitable and efficient apparatus is not in the writer's power. Many materials and arrangements, however, naturally suggest themselves, and some of the more prominent of these may, perhaps, be mentioned.

It is patent that, in order to reduce the cost of the predominating item of expense, viz., current, to a minimum, it is imperative that the amount of matter surrounding the blocks, consistent, of course, with good heat insulation, should be reduced to utmost limit. In the experiments referred to, this condition was most imperfectly studied. A considerable mass of brickwork became heated to bright redness, at the expense of current, by contact with the blocks, and the extensive external brick surface was moreover very inadequately protected by the slag wool from the cooling influence of the surrounding air. The vessel in which the blocks are packed should, by preference, be either cylindrical or rectangular in form—the latter to suit the shape of the blocks—and of large enough dimensions, both in height and diameter, to be convenient for packing and unpacking the blocks. The vessel should stand in an upright position, and it should be made as thin in the wall as possible of a material which is practically impervious to air. Probably as good a material to use for the purpose as any would be the fire clay employed for making salamander crucibles. The vessel should be closed both at the top and bottom by a stout carbon plate or disc, the bottom one being cemented into position so as to admit no air at the junction with the vessel. The platform on which the vessel rests might, perhaps, best be made of the porous fire clay of which Fletcher's furnaces are made.

The question of how best to prevent the escape of heat at high temperatures is doubtless one in which a good deal of improvement might be made on attainments already arrived at, and it would form an interesting subject for investigation. Without possessing any special experience on the subject, the writer would propose that the vessel should be surrounded by two, three, or more (as may be found desirable) movable cylindrical covers of increasing dimensions, and made of the same material as the platform. Each cover, which must perforce have a small hole at the top through which the conductor, conveying the current, must pass, should be made as thin as practicable. The lower rims of the covers might fit into concentric grooves made in the platform, each groove being filled with powdered charcoal or lampblack. A series of air spaces would thus surround the vessel at regular intervals, and these would be likely to effect good heat insulation, whilst the actual mass of solid material employed would be reduced to a comparatively small cubical bulk. The arrangement would further possess the advantage of easily and expeditiously effecting the cooling of the blocks at the close of an operation by the simple removal of the covers or shades.

It may well be that better heat insulation and more conveniently arranged apparatus might be constructed on other lines. Many insulating materials packed round the vessel, such as asbestos, slag wool, lampblack, metallic oxides, &c., might perhaps be arranged to give excellent results. In the selection of such substances, it would be well to bear in mind the different specific heats which the various substances possess, although other properties and considerations may very likely far outweigh this one in importance.

All the world knows of the remarkable success which has attended Prof. Dewar in his experiments on liquid air and its preservation by means of exceptionally perfect heat insulation, effected by surrounding it with an intervening vacuum. The application of this principle to the form of electric furnace under discussion would doubtless be productive of highly successful results. The manner of constructing apparatus involving this principle is, however, not so very apparent, although it is a problem which would be well worth attempting.

Another principle, which might be made to give satisfactory results, would be that of heating the outside of the vessel by means of gas or otherwise, and so lessen the escape of heat generated by electricity. A loose outside fire-clay mantle might be arranged round the vessel, inside which gas was made to burn, or heated gases to circulate. The external surface of the case would not need such careful protection from the outside air, and the cooling down at the end of the operation could be easily effected. The total energy expended by this means of conservation of temperature would naturally be greater, but not necessarily more costly by reason of the difference in cost of heat produced by gas and that produced by electricity.

As regards the current needed for the generation of heat, it would doubtless be necessary to have the power of considerable variation of electromotive force. The amount of energy consumed would depend almost entirely upon the perfection of the surrounding heat insulation. With this very perfect, and with sufficient time, the temperature requisite for the proper carbonisation of filaments should be reached with a comparatively small current. The manner in which the current is applied and the duration of the operation to give the best results, are points which can only be determined by actual experience with any particular form of apparatus.

It may, perhaps, be idle to let the imagination run too freely on the advantages that are likely to result from the carbonisation of filaments by electrical means over methods of heating by fuel, before they have been actually demonstrated. Some advantages, however, are highly probable, and a few of them may be enumerated.

1. The wear and tear of the apparatus is likely to be appreciably less for the following reasons:—(*a*) There would be more regular heating and cooling of the apparatus; (*b*) there would be less lifting and moving about of the apparatus both in the heated and cold condition; (*c*) there would be an absence of fluxing material to destroy the apparatus.

2. The precision with which the current could be regulated ought to ensure greater uniformity in the quality and resistances of the several batches of filaments turned out in the regular course of manufacture. The defect inherent in the use of crucibles heated from an external source, due to the impossibility of heating equally all parts of the contents whilst raising the temperature would be wholly absent.

3. The labour needed to work the process would be of a much more agreeable and less arduous description.

In addition to these probable advantages, it is quite possible that the electric method might possess others of an important nature. The temperature of the furnace might be easily raised to a very high degree, and this condition might be conducive to producing filaments of a very dense and durable description. Further, by reason of the compact and isolated manner in which the apparatus might be arranged, it would be possible to perform the carbonisation under unusual physical and chemical conditions, such as in vacuo or under pressure in air or hydro-carbons, or other gases, by enclosing it in a suitable chamber. Such altered conditions might result in producing new and desirable results.

On the question of initial cost of apparatus and of the electric energy consumed, it will be prudent to venture no remark other than that both are likely to be in favour of electricity as compared with heating by fuel.

The electric furnace in various forms is now being employed in a number of industrial manufactures, both in the smelting of metals and in the preparation of substances such as carbide of calcium, graphite for electrodes, carborundum, &c., and there seems no reason why it should not be also successfully applied to the carbonisation of filaments.

ELECTRICAL ENERGY (GENERATING STATIONS AND SUPPLY).

(*Concluded from page* 638.)

At the sitting of the Joint Committee under Lord Cross on Thursday last week, Major Cardew, electrical adviser to the Board of Trade, said the Board of Trade regulations did not provide for the safety of the employés at generating stations, nor did they undertake any inspection. When, however, accidents had been reported to the Board, he had been instructed to inquire into the circumstances. As regarded general danger from high pressure, he did not think any danger could be apprehended by the public if laid in proper mains underground. In the case of overhead wires he was distinctly of opinion that danger increased with the increase of electrical pressure. In regard to interference with telegraphs and telephones, he considered that that could be avoided absolutely. Under the provisional orders of the Board of Trade, strong protective clauses were inserted. In the case of electrical powers for traction, where an uninsulated return was employed, some interference might be unavoidable. The clause settled by the Joint Committee should not be inserted in any Bill providing for general electrical power, since it permitted the use of uninsulated returns. The usual provisional order clause should be inserted. The Board of Trade sanctioned the use of the overhead system of electric traction in cases where no local objection was made. The danger to the public was not great. In 1889 the Board sanctioned a pressure of 10,000 volts for London, and that pressure had been in use since, without any injury to the public. He was quite satisfied that underground mains could be made perfectly safe.

The Chairman: You do not say the same of overhead wires?—Not at all. I am afraid that in the case of overhead wires there are possibilities of danger which can hardly be avoided altogether.

There have been accidents to employés?—Yes.

Can you suggest any regulations for their protection?—I think regulations could be made, and I have myself prepared some draft regulations; but it was rather a legal question as to how they could be protected, not being members of the public.

Mr. Kimber: Is the unsafety of overhead wires preventable?—I do not think you can say that it is entirely. We can make regulations, but in the event of these regulations not being entirely complied with at all times there might be accidents. Such things as gales and falling trees might affect the overhead wire which would not affect the underground wire.

What is the highest pressure which under any circumstances the Board of Trade will permit?—10,000 volts has been used.

Would they under any circumstances permit more?—I only speak as their adviser, and I think in some cases we should permit more in the case of underground wires. I do not think myself there can be laid down an exact limit beyond which it could be said the danger would become so appreciable that the thing should not be permitted.

Has any steps been taken by the Board of Trade to get statistical information with regard to the use of electrical energy in America?—We have not asked for information as to the working of these very high pressures.

Don't you think it would be advisable to do so; they are far in advance of this country in regard to the application of electrical energy?—In traction they are; I do not think they are in advance of us as regards the electric light.

Do you apprehend that there will be an increased demand for the use of power?—I think there will; I think it is coming.

You are aware that chemical works are being erected now in which as much as 4,000 horse-power is required?—Yes; that is a special industry which is kept very much to itself. The chemical industry opens a wide field for electrical energy.

Lord Balcarres: May I take it that your regulations have been sufficient to make it almost impossible for people who wish to carry energy to do it with overhead wires?—I should not have thought so.

Is it common in this country for energy to be carried overhead?—No; it is done in certain cases.

It would be cheaper to carry it overhead?—I do not think it would for any purpose of general supply. If you have to take off service wires to many different consumers work, with overhead wires would become impracticable.

But the same thing applies with underground wires?—There is a convenience for laying down a heavy mass of copper in underground mains which would be almost impossible overhead. The practice of the Board of Trade has been generally to discourage the use of overhead wires.

And you have been very successful in that direction?—It has not been much adopted.

By Mr. Ashton: He would not be prepared to advise any relaxation of the existing Board of Trade regulations for overhead wires.

The Chairman said that Mr. Kimber had asked for an answer to a question with regard to the price at which the Central Company of London had agreed to supply energy in bulk to the Westminster and St. James's Companies.

Mr. Balfour Browne: No price is fixed, but the basis on which it will be fixed is that in consideration of the two companies supplying the capital for and jointly promoting the Central Company, each shall be entitled to take as much energy as the other on terms to be agreed or otherwise settled, and that any excess taken by either company over what is taken by the other shall be paid for on the basis of the average cost price of the whole energy generated during the year, plus a reasonable profit.

Mr. Kimber: The effect would be that if the sliding scale principle of gas companies was applied to electric light companies, those companies would be able to make two profits?—No, I think not. If there is a difference as to what profit is to be allowed the Central Company, that is to be fixed by arbitration.

Mr. Pember, Q.C., then addressed the Committee, and said he appeared for companies whose interest it was to supply electricity for power and light inside their own districts. The main points he had to consider was, first, compulsory purchase, then power of breaking up the streets, power to supply within their district whether the local authority liked it or not, and even it might be in competition with the local authority. There were minor questions such as the sliding scale, notice to persons affected, and so on. As to the question of purchase, there had been evidence given of the great difficulty at present of obtaining land, and in the case of the Chelsea Company, the company were asked to buy adjoining property at a cost of over £30,000. That was but one instance of hundreds, which showed the necessity of having compulsory powers of purchase. He asked what real distinction there was between giving compulsory powers to railways than to electric lighting companies? but, of course, it went without saying that the lands should be specified. All that was necessary to be done in that regard was provided by the standing orders of Parliament now. It was perfectly clear that unless the compulsory power was given an individual could absolutely prevent the public enjoying in a particular locality the comfort and convenience of either electric light or electric power. Evidence had been given of the prohibitive prices put upon the only available sites, and there was also the nuisance clause, which interfered greatly with the supply. There was no doubt that it was shown from experience in the use of electricity that the nuisance clause was a mischievous one, and ought no longer to be left in the hands of any man. He would assimilate the practice of Parliament with regard to electric light with that of ordinary railway schemes. Each case should be considered on its merits, and Parliament should reserve all power to itself and not hand it over to any other body. With respect to notices being served on residents in the neighbourhood of land to be acquired for a generating station, that was a most expensive operation, and he contended that notice should only be given to the owner of the land, and that the local companies should receive notice and have a *locus standi* to object. If energy was to be generally available, it must be cheaply supplied, and if it was to be cheaply supplied it must be supplied in large quantities, and that meant by single undertakers in very large areas, and that again meant over the districts of several local authorities. There they were met by the jealousy of the local authorities, which applied to the sale to individuals within the districts. And next as to the breaking up of the streets. He asked the Committee to refuse to say that only the local authority should have an order in a district; but, of course, it would be for Parliament to pronounce hereafter as to any Bill. An absolute veto by the local authority should be removed, and he would give them a *locus standi* in place of veto. With respect to purchase, he saw the greatest difficulty in accommodating the power of purchase to local authorities for schemes for the supply of electrical energy over large areas. He would say, "Don't make an attempt to accommodate the present powers of purchase to undertakings in these large areas." In conclusion, he would suggest compulsory power of purchase, and the sweeping away of local veto with regard to the laying down of pipes and the general supply of energy for light and power. At the same time he would provide for a liberal *locus standi*, so that every case might be thoroughly well decided on its merits before Parliament, and every fact brought forward and every interest represented.

Mr. Balfour Browne, representing new companies desiring compulsory power for purchase of sites in order to supply in bulk, said he objected altogether to giving the local authority an absolute veto, either as to a site, or with regard to the breaking up of streets. He saw grave danger to the public in giving the authorities that power, and the result of their present powers with regard to tramways did not seem to be satisfactory. The consent of the local authority should be subject to an appeal to the Board of Trade; but the Board of Trade should not regard the opinion of the local authority as the main consideration. At present it was true that the Board of Trade could dispense with the consent of the local authorities, but they never did so. The Board had such a respect for the local authorities, that in 60 cases he knew they had refused consent to companies. They had not the slightest objection to the local authorities undertaking the work; but what the local authorities were seeking to have recognised was a right in streets which they had not got by law. As to the conditions to be laid down on an electric light undertaking, such as he represented, he considered the powers of the local authorities were large enough at present. He asked what would be the condition of the gas and water supply had it not been for private enterprise. Local authorities would not touch such things unless there was a profit to be made out of it. At the present time electric light was not supplied in many districts, because it was known that as soon as a profit was shown, the local authority would step in and say it was time to purchase it. He asked the Committee to leave out the purchase question altogether in companies such as he represented.

Mr. STEVENS said he represented the existing London companies other than the promoting companies. Following on an inquiry by Major Mandarin, the principle which had been acted upon was to confine a company to a definite area, and allow a limited competition. Speaking broadly, the endeavour of the Board of Trade had been to secure in every district two companies and no more. It was a remarkable fact that there had been an entire absence of evidence before the Committee that the present system had given cause for complaint. The further development of electrical energy could only be effected by the mode in which Parliament dealt with those who had already invested their money. He agreed that there should be compulsory power of purchase, and that an existing company should have power to go outside its area for a site for a generating station. But it was also asked that new companies should be allowed to come into a district and supply anywhere free entirely from the conditions imposed upon the existing companies. That was a distinct revolution in the principles which had heretofore been applied. If it was agreed that those new companies should be exempt from purchase, it would be the commencement of a new system diametrically opposite to all Parliament had already done.

Lord CROSS: Do you contend that under the existing system the development has been all we could wish, and that we are bound to this system?—No; all I ask is that whatever is done shall not be unfair to existing companies.

Mr. WORSLEY TAYLOR addressed the Committee on behalf of a number of Corporations, who, he said, were largely interested in the matter, for local authorities had invested $3\frac{1}{2}$ millions of money in electrical enterprises. On the question of compulsory purchase the Corporations were entirely in agreement with the companies, for it was as necessary to the Corporations as the companies. On the question of nuisance they were also in agreement. On the question of the control of the streets, that was the matter with which the Corporations were most vitally interested. *Primâ facie*, it should be admitted that there should be a perfect control over the breaking up of the streets by the Corporation, but it should be subject to appeal to the Board of Trade. Then assuming their consent was dispensed with, they should have power over the route and the way the work was to be carried out, and they should have power to undertake the work themselves.

Mr. COWARD, representing the London County Council, contended that the Council differed from all other authorities inasmuch as they were the controlling authority over the electric lighting companies, whereas the vestries were the local authorities. Under these circumstances they contended that the Council was the authority in whom the ultimate power of purchase should be vested.

This concluded the evidence and addresses, and the Committee adjourned till Monday for the consideration of their report.

The further sittings will be private.

LONDON COUNTY COUNCIL.

AT the weekly meeting on Tuesday the following electrical matters were considered:—

TRANSFER OF LIGHTING POWERS.

Mr. B. F. C. Costelloe (chairman of the Local Government Committee) obtained the sanction of the Council to the postponement of the report of the Committee in regard to the recent conference with representatives of the London vestries and district boards to consider what powers now vested in the Council should be transferred to those local authorities. That portion of the report of interest to our readers is as follows:—

"The Conference proposed: 'That the powers of the Council under Electric Lighting Provisional Order Confirmation Acts, as regards the appointment of inspectors, provision of testing stations, and exercise of powers with reference to price and energy of the supply of electricity in a district, should be transferred to the local authorities.' We are of opinion that it is most essential that these powers should be exercised by one authority, having regard to the additional cost that would of necessity follow a transfer of the powers to the local authorities, in connection with testing stations and plant, and also having regard to the necessity of a general supervision and uniformity of treatment in these matters which involve more than local interests. We recommend that the powers of the Council under Electric Lighting Provisional Order Confirmation Acts, as regards the appointment of inspectors, provision of testing stations, and exercise of powers with reference to price and energy of the supply of electricity in a district, be not transferred to the local authorities."

"The Conference proposed: 'That power should be given to local authorities to alter or remove overhead wires in their districts in the event of the company refusing to do so.' We are of opinion that the London Overhead Wires Act, 1891, already gives to the local authorities all the powers sought for by the resolution."

LONDON UNITED TRAMWAYS.

The Highways Committee reported that, by the London United Tramways Bill, it was proposed to repeal Sections 17 to 28 of the London United Tramways Order, 1895, relative to the use of mechanical power, and to authorise the use of electric traction on the whole of the company's system within and without the County of London. The Council, whilst it had not offered objection to the conduit system, had consistently refused consent to the introduction of the overhead system, and had therefore petitioned against the London United Tramways Bill. In this connection the Highways Committee stated that they proposed that evidence in support of the Council's petition should be given by Mr. Baker (vice-chairman of the committee), by the chief engineer, by the chief officer of the fire brigade, and by an expert, whose evidence should be specially directed to the practicability of using the conduit system in London in conjunction with an overhead system, if established, on the company's lines outside the county. The Committee accordingly recommended that the Parliamentary Committee should take the necessary measures for supporting the petition against the Bill in the manner suggested. This recommendation was also opposed, and having passed the time limit was accordingly adjourned.

THE TELEPHONE QUESTION.

Pending the report of the Government Select Committee on Telephony, the Highways Committee expressed the opinion that it would not be well for the Council to proceed further with reference to the proposed agreement with the National Telephone Company in regard to the conditions under which permission had been given in certain cases for the placing of telephone cables underground. The Committee thought, however, that as under the conditional consents the company had executed certain works, the company should be required to enter into an agreement embodying certain conditions in regard to the works already carried out. The Committee, therefore, recommended that the telephone company should be requested to enter into an agreement undertaking (1) to alter any telephone line if and when required by the Council, and (2) that if and whenever the Council desire to adopt electric traction on any tramway belonging to or leased by or under the control of the Council, which passes along any street or part of a street in which any line of the company is laid, the Council may require the company to alter any such line, or portion of such line, or to remove the same to such position as the Council may require, and thereupon the company shall, without any claim for compensation against the Council or its lessees, proceed to make such alteration in the position of such line as no earth return but a complete metallic circuit is provided and used, the Council or its lessees shall not be liable to the company for any interference with, or prejudicial effects produced upon, the cables or wires or the working of the same, or upon the operations of the company, by reason of such use of electricity upon such tramway.

TRANSFORMER BOXES.

The County of London Electric Lighting Company having given notice of intention to construct 15 transformer boxes in Camberwell, the Highways Committee reported that the works mentioned in the notice were a repetition of those works which were expressly disapproved by the Council on January 25th. At that time the appeal of the same company to the Board of Trade against a previous decision of the Council, disapproving the construction of certain other transformer boxes proposed to be constructed by the company, was pending. The Board has since then, however, allowed the appeal, and authorised the company to construct the transformer boxes referred to, subject to the usual conditions. This decision was reported to the Council on March 29th last. The Committee were of opinion that, in view of the Board's decision, the Council could no longer withhold sanction to the construction of the transformer boxes referred to in the present notice; and should the Council adopt the alternative course of making no order with reference to the notice, the company could proceed with the works without any restrictions. The Committee therefore recommended, and the Council resolved, to conditionally approve the construction of the transformer boxes in question.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

MR. LEONARD ANDREWS, the engineer and manager of the Hastings Electricity Works, had an opportunity of describing the latest form of his alternating current non-return or discriminating switch and its uses at a meeting of the Institution of Electrical Engineers on Thursday of last week. The paper, entitled "The Prevention of Interruptions to Electricity Supply," was read in the hall of the Society of Arts.

Our readers will remember the description we gave nearly two years ago of the switch gear in the Hastings station, when the earlier pattern of the Andrews switch was illus-

B

trated and described. Mr. Andrews has also given a full account of the device in a paper read before the Northern Society of Electrical Engineers last year. The present pattern of the arrangement differs from that before published in its mechanical details, the principle remaining much the same.

Mr. Raworth opened the discussion, and reminded his audience that he was a bit of an inventor in the field of discriminating switch gear himself. He could not allow himself, however, to say anything to detract from the credit due to Mr. Andrews by taking honour to himself who had done so little. Mr. Andrews had, he thought, hit the right nail on the head by using such discriminating fuses on interconnecting links on the distribution system. It was well known that when a generator went wrong it caused the fuses on the good machines to burn down first, and an example of this had occurred in the City of London station, where, on one occasion, every fuse in the station had gone, and the lights were all extinguished.

Some years ago Mr. Raworth designed a discriminating fuse arrangement, which was described in our columns. It was based on the principle of two paths for the current; a little transformer sucked current through one of these, which formed a bye-pass to a thermal fuse-wire, when the energy was passing out; but when a reversal of flow took place, the transformer caused the current to be diverted through the fuse, which melted and opened the circuit. Much time and money was spent on this device, and at last it was got right; but the time element interfered with its utility, as the time taken by the fuse to melt was often sufficient for the machine to burn out.

Mr. Andrews had done well to go in for the mechanical arrangement, and had shown very great ingenuity in carrying it through a great variety of alterations in detail design, until at last it had reached the form exhibited. Its great merit is that it can't be joggled into working, but must be tickled. While some engineers will say, "Oh! we have no interruptions to our supply," an apparatus of this kind may be termed an apparatus for relieving the mind of the electrical engineer from anxiety. Even with machines of large self-induction there is another point to consider; one cannot always guarantee or be sure that a fault will come on in the end coils, and if an intermediate coil proves faulty, the self-induction of a few will not cut the current down materially. The switch had been tried under very trying conditions, and large currents could be broken under water without appreciable spark. Mr. Raworth thought he had designed more switches than any other living man, but he was not going into competition with Mr. Andrews on this switch, which he congratulated him upon as not merely a switch or fuse, but a device which had been worked out into a system.

Mr. Chattock thanked the author for his paper, as he had made one or two attempts at a similar switch himself, and hoped this summer to perfect. All station engineers would confirm what Mr. Andrews had said as to the unreliability of fuses. This switch meets the necessity of the case. With regard to fig. 7 of the paper, a short-circuit on the connecting main between the two sub-stations would be likely to blow both feeder fuses. Mr. Andrews afterwards explained that he would in practice place thermal fuses at each end of this connector.

Mr. Lawson did not go so far as Mr. Andrews would go, as he thought it undesirable to have any sensitive mechanism, and on switching on the switch might give trouble. With reference to double feeders to sub-stations, he thought this very reliable, but rather expensive. He also was of opinion that some of the saving in the Hastings coal bill might reasonably be attributed to an improved load factor. In his reply, Mr. Andrews pointed out that while the coal per unit might go down from this cause, it could hardly be expected that the *total* coal bill would be diminished.

Mr. Raphael believed that while Mr. Andrews suggested that consumers' fuses should blow only at 300 per cent. overload, the fire insurance offices would insist upon a lower figure. He considered that leakages to earth and "shorts" should be dealt with in different ways, and to guard against the considerable danger that might arise from the flow of a leakage current of only a few amperes, he had devised an arrangement which would cut off the wiring from the supply where an iron pipe conduit system was installed. This consists, briefly, of a fuse in the earth wire to the metal conduit. On the fuse melting by leakage current, a lever is let go, which falls and short-circuits and earths the wiring blowing the house fuses. There was, however, no chance of this system being adopted, as it would cost a few shillings, and in these days of cut prices contractors were not inclined to take up anything that would increase the price of work. Even without such safeguards, any system of wiring is a better risk for insurance companies than gas.

Mr. Bathurst reiterated certain arguments in favour of the adoption of electric-proof pipes or insulated conduits, which are probably not new to the majority of our readers, although ably put by the speaker.

Mr. Weekes drew attention to the want of novelty in the principle of non-return or discriminating devices, and showed that such had been in use with continuous currents for some years, while Mr. E. K. Scott was understood to animadvert upon the design of certain of Mr. Raworth's switches and the troubles out of which the City Company have passed.

Prof. S. P. Thompson, who occupied the chair, pointed out that there is a long step between discriminating devices for continuous and alternating currents, that the wattmeter may be used—as Mr. Andrews practically does—to *discriminate* with alternating currents. While the apparatus confers a benefit on alternate current workers, a machine should not come to pieces if "shorted," or put in out of phase, and closed his remarks thus: "A fuse is a very excellent thing to do without."

Mr. Andrews replied by saying that his switch was just the thing for synchronising in a hurry; that one never knew what fuses would do; a circuit cannot be opened too quickly, and that often a short occurs which is not a case of two pieces of copper coming together. His extended remarks, delivered with enthusiasm of his subject, formed a further exposition of the interesting subject, and the meeting closed with a general feeling of gratitude to Mr. Andrews for a good discussion.

CORRESPONDENCE.

Ether and "Surface" of Matter.

A great many phenomena are endeavoured to be explained by motions of or in the ether. But considerations in regard to a decrease or increase of *surface* in changes of configuration of or in matter, appear not to be sufficiently appreciated in reference to motion, energy, &c. But it may be taken that wherever energy, so-called, in any form, is given out from any system of matter, that system must diminish in *surface* and *vice versâ*. It does not matter whether the mass under consideration be the sun, a watch-spring, ions, or what not, a simple or complex molecule, or the visible universe.

In some mysterious way the organs of our bodies appear to absorb and give out energy by such a change of surface. In fact, it is not by any means difficult to explain much of the phenomena of life and death by it. Most certainly thermal and electrical phenomena in chemical change can be explained on this basis. If the particles of any two or more bodies have together greater surface before combustion, association, combination, &c., than afterwards, then there will be a rise of ether pressure or potential or moving power upon the resultant matter surface.

The total change in *surface*, and the rate of increase or decrease of such change in surface, will explain and render clearer a great many thoughts about matter and motion. However, if we accept the idea of matter in all forms being charged (on its surface) with another something which we call the ether, then we should have no difficulty in imagining how, by a change in *surface*, there will be an *in*-rush or *out*-rush of this ether, which we may express by − or + sign respectively. *Surface* seems to be the key to it all. Tyndall asked (1862): "*May not the condensed ether which surrounds the atoms be the vehicle of electric currents?*" But if atoms dissociate [we must also suppose the ether itself capable of association and dissociation—Maxwell had the idea in his mind of a molecule of electricity] as to increase the surface, there will be a fall in the density of the ether, and if they associate (or aggregate) as to produce a decrease of surface, there will be a rise in the density of the ether, which may have explosive or gentle expansive *force*.

J. C. R.

Books Received.—"Science and Engineering, 1837-1897." By Chas. Bright, F.R.S.E. Pamphlet, 24 pp., published by Messrs. Archibald Constable & Co, 2, Whitehall Gardens.

"Industrial Electricity." By A. G. Elliott. (Translated and adapted from the French of Henry de Graffigny. Published by Whittaker & Co., London. Price 2s. 6d.

"Alternating Currents of Electricity, and the Theory of Transformers." By Alfred Still, A.M.I.C.E. Published by Whittaker and Co., London. Price 5s.

Catalogues and Lists.—Messrs. Wimshurst, Hollick and Co., of Commercial Road, E, who have offices at 17, Victoria Street, S.W., send us a 16-page pamphlet in which the general utility of electric cranes and lifting gear is demonstrated. The letterpress shows that cranes driven by electric power and fitted with Hollick's patent gears and motors, are cheaper in first cost, in repairs, and in working, than cranes worked either by steam or hydraulic power. Some comments are made upon the general efficiency of cranes, and illustrated descriptions are given of Hollick's patent balanced friction gear electric overhead travelling crane, electric goods lift and warehouse crane winch, also of electric cranes in use at the West India Docks, and at the wharves and works of firms in different parts of the country.

The Nottingham Engineering Company, Limited, of Radford, Nottingham, have issued an illustrated catalogue of shafting, bearings, couplings, and other fittings, together with a cipher code for ordering by telegram. In tabulated form there are given sizes of shafting required for a given horse-power, and the number of revolutions; also graduated price lists, covering many pages, of bright turned steel and iron shafting. A great number of power transmission accessories, couplings, wall boxes, plummer blocks, brackets, hangers, pulleys of various kinds, &c., are included in this list.

Messrs. Heath, Snoxell & Co., Limited, of Birmingham, have issued a handy pocket list, which is a photographic reproduction, considerably reduced, of their larger catalogue, giving particulars of electric motors for all purposes, and dynamos for electric lighting stations, transmission of power, and electro-deposition of metals. There is a specification of standard continuous-current dynamos, also illustrations and tabulated details and prices. Prices and general particulars of motors, and ammeters and voltmeters are given.

Messrs. Chas. Jennings & Co., of 90, Cannon Street, E.C., have issued an illustrated list of isotropic iron magnet forgings and armature stampings, steel magnet castings, and transformer stampings. The results are given of some tests made by Prof. Ewing on steel magnet castings which were manufactured for Messrs. Jennings. This firm is also sole representatives for the United Kingdom of the extensive copper works known as the Usines Mouchel, Boisthorel, France, and, therefore, high conductivity copper is included in the list.

The Crystal Electric Lamp Company, Limited, v. Pearson.—This was a claim made by the plaintiff company at the Lord Mayor's Court last week to recover from the defendant, Mr. A. Pearson, a sum of £20 4s. for electric lamps supplied. The defendant said that a half-brother of his (Mr. Bundy) and a Mr. Roe started the business of the Decorative Glass Company. He had ordered the goods of the plaintiffs for that company, and had afterwards given the authorisation, on the condition that he should either receive the balance of the electric lamps or be given an authority to collect the accounts due to the plaintiffs for the lamps. The plaintiffs would do neither, and therefore he declined to pay for the lamps supplied. The jury found a verdict for the plaintiffs.

Electrical Exhibits in Manchester.—Messrs. F. H. Royce & Co., electrical engineers, Manchester, have supplied the dynamo and lamps for the fairy fountain at the Brewers' and Allied Trades Exhibition now being held at St. James's Hall, Manchester. They have also, at Stand No. 74, an exhibit of the transmission of power by electricity. The National Gas Engine Company exhibit a small electrical installation consisting of one 5-H.P. brake National special high speed electric light engine, with various fittings, and driving dynamo. They have also specimens of electric light lamps and fittings. An electric piano is shown by Messrs. Guldman, Market Street, Manchester.

Electricity in Cork.—The Cold Storage Company, Limited, have decided on getting rid of their gas engines, and in a very short time electric motors will replace them. The order for the motors was given to a local firm.

Embezzlement.—L. A. Longley, accountant, was charged at the Guildhall Police Court, last Saturday, with embezzling £4 11s. received by him on behalf of his employers, the Electric Light Insurance and Maintenance Company, Limited. Prisoner blamed his betting habits. He was remanded.

Forthcoming Book.—Messrs. Emmott & Co., Limited, have in preparation an entirely new work by Mr. C. N. Pickworth, Wh. Sc., entitled "The Indicator Handbook: a Practical Manual for Engineers."

The "Ideal" Engine.—Messrs. Daniel Adamson and Co., of Dukinfield, near Manchester, have brought out an exceedingly neat list in the American style, of their "Ideal" high art engine. This steam engine, which is described and well illustrated, is automatic and self-oiling, and is said to be specially adaptable for direct connection, because of its range of speeds, quiet running, absolute regulation, perfect balance, compactness, and automatic lubrication. The advantages claimed for the "Ideal" engine are briefly stated, and there are some general remarks on the importance of good lubrication. The "Ideal" tandem compound engine is described, and there are some comments on the economy in compounding, also on the governor and the "Ideal" throttle valve. Tables of dimensions and powers of the engines are given. The list has been very well put together. Mr. Frank Jordan, of 15, George Street, Mansion House, E.C., is London agent for Messrs. Adamson.

Langdon-Davies Motor.—The increased facilities for manufacturing now available at the new works of the Langdon-Davies Motor Company, referred to in our last issue, have already enabled them to effect a reduction in prices, particulars of which are given elsewhere.

Private Telephone Systems.—Mr. R. S. Blackburn is putting in an extension of the Long Eaton Co-operative Society's telephone system, connecting various additional branches with the head shop. He is erecting a system of fire and ambulance telephone call stations for several out-districts and 14 firemen's houses for the Urban Council of Long Eaton, and is also laying down a complete telephone system for the Blackley Co-operative Society.

Reavell v. Brotherhood.—This was an action brought before Mr. Justice Grantham and a special jury by Mr. William Reavell against Mr. Peter Brotherhood to recover damages for wrongful dismissal and for breach of contract. Mr. John F. P. Rawlinson, Q.C., and Mr. Whatley (instructed by Mr. Percy J. Nichols) appeared for the plaintiff, and Mr. Bucknill, Q.C., and Mr. Alfred Lyttleton (instructed by Messrs. Cope & Co.) for the defendant. Mr. Rawlinson stated that the action had been settled on the terms of the defendant paying to the plaintiff the sum of £1,000 damages and costs (in addition to the sum of £519 4s. already paid into Court), the defendant also fully withdrawing all charges of every kind pleaded as a justification for the dismissal of the plaintiff. Mr. Bucknill for the defendant assented.

The Shannon Power Scheme.—The proposals of the Shannon Electrical Power Syndicate were again before the Shannon Fishery Conservators last week. Mr. Fuller, the engineer, submitted a tracing showing the proposed canal. Various questions were drawn up for the syndicate to answer in regard to the general details of the undertaking.

The Smoke Nuisance.—There has been a correspondence on this subject in the *Westminster Gazette*. One writer says that ever since the South Wales coal strike commenced the big chimneys of the electric lighting works in East Street, Manchester Square, and Davies Street, Grosvenor Square, have been vomiting forth—both by day and by night—volumes of the blackest and foulest smoke.

South African Electrical Notes.—The May issue of the *British and South African Export Gazette* contains the following items of electrical interest:—

A trial indent of 12 sets of railway carriage electric lighting apparatus has been placed with Messrs. J. Stone & Co., Deptford, S.E., by the Cape Government Railways, to be followed by the necessary orders for a general introduction of these fittings should the experiment prove successful.

The Kimberley electric lighting scheme having been approved, orders may shortly be expected to be placed for the needful material.

Tenders for arc lamps and insulated cable were called for last month by the Johannesburg Town Council.

The electrical motor driving the central mill at the Transvaal Gold Mining Estates Mine having completely broken down, the order for a new motor in substitution for it will be immediately placed.

A power plant has just been installed at the York Gold Mine, comprising two belt-driven 50-H.P. three-phase inductor type generators, running at 750 revolutions per minute and supplying power to two 24-H.P. motors coupled to belt-driven pumps; also a 3-H.P. motor connected to a centrifugal pump; and several small motors for various kinds of machinery, including one of 9-H.P., coupled direct to a continuous current dynamo of 15 volts 300 amperes output, for cyanide work.

An electrical plant recently sent out to the Vogelstruis Gold Mine by the General Electric Company, Manchester, consisted of two 150-k.w. three-phase generators, belt-driven at a speed of 300 revolutions per minute, a frequency of 30 cycles and a pressure of 950 volts; three triplex single-acting pumps, with plungers 6½ inches by 8 inches, coupled direct to 35-H.P. motors, running at 360 revolutions.

The generators of the General Electric Power Company, Johannesburg, were made by Messrs. Brown, Boveri & Co., Baden, Switzerland, and their fly-wheels by Messrs. Yates and Thom, Blackburn, the shafts of the fly-wheels being supplied by an American firm.

An electric lighting plant, manufactured by Messrs. Thomas Parker, Limited, Wolverhampton, has been installed at the British South Africa Mills, Bulawayo.

Spain.—The *Consular Journal* says that although the demand for cables and other electric appliances is increasing in Spain, English manufacturers are not benefiting at all by it. An opening for a large supply of water, electric light, and gas, materials will be afforded by the proposed formation of a company to provide the town of Oviedo with water, electric light and gas, for a term of 99 years. The capital has been already subscribed.

S. Z. de Ferranti, Limited.—Messrs. S. Z. de Ferranti, Limited, late of Charterhouse Square, London, have now transferred the manufacture of meters to their new works at Hollinwood, Lancashire. The London works are closed, but a depôt has been opened at 29, St. John's Square, Clerkenwell, for dealing with their meter business in London and the South of England. All communications for that district should be addressed to St. John's Square. The remaining business will be dealt with from Hollinwood.

The "Underground."—We have received a small leaflet by Mr. Ernest Callard discussing the question of the ventilation of the Metropolitan Underground, which has been receiving so much attention lately.

ELECTRIC LIGHTING NOTES.

Alloa.—The Alloa Public Baths and Gymnasium, which Mr. John Thomson Paton has just handed over to the town of Alloa, is fitted up with electric light throughout. The work was carried out by Messrs. Mavor & Coulson, Limited, whose patent concentric watertight system has been installed.

Bath.—The new generating plant is ready to be put in position as soon as the building contract is completed. Seventy-five of the new arc lamps have been fixed.

Belfast.—When the report of the Electric Committee came before the Corporation last week, it was stated that the engineer had reported that the Acme Gas Engine Company had refunded £1,593 5s. 6d. in respect of the three engines which were to be returned. The Town Clerk said the Acme engines were not found to come up to the undertaking given by the company, and it had been agreed to take them back and repay the money. There was a passage in the report relating to the subject of electric traction, but Councillor Andrews was absent. The matter is under consideration. The engineer reports that for the past quarter's working, there was an increase in the receipts of about 50 per cent., and an increase of the output of about 55 per cent., as compared with the corresponding period of last year.

Bloemfontein.—Definite conclusion is about being come to, says a London contemporary, with regard to the long-mooted electric installation for the Orange Free State capital. According to last advices, it has now been decided to submit the plans and the several tenders to an engineer in Europe for report. The tenders sent in varied in amount from £12,000 to £30,000.

Bournemouth.—At the Town Council on Wednesday last week it was recommended by committee that the Council should generate the electricity necessary for lighting the pier, pleasure gardens, and winter gardens, and invite tenders. The town clerk stated that in 1895 the Local Government Board gave sanction for the borrowing of about £4,500 for the purpose, any amount decided on to be repaid within seven years. The Board had now written asking if anything had been done by the Corporation, and if not, and the Council did not propose to act on it, that the sanction should be given up. The scheme the Committee recommended was to take up sanction to the amount of £1,600 for the material and wiring, and £900 for generating electricity, and the surveyor had prepared a scheme to utilise the present pumping stations and light the pier, winter gardens, and pleasure gardens; but the sum would have to be repaid in three years, that being the limit of the original period of sanction. The scheme was agreed to after a discussion on arc v. incandescent lights. The tender of Messrs. Cash, Robinson & Co. was accepted.

Bridlington.—The Council has resolved to light the parade on Sunday nights with gas instead of electricity.

Cardiff.—Complaints have been made to the Lighting Committee of alleged erratic measurement of the current, consumers considering that they are charged for more than they use. The Lighting Committee is referring the matter to a Local Government Board inspector, and is writing to other towns to know whether similar complaints are made there.

Cheltenham.—The minutes of the Lighting Committee which were adopted by the Council last week, state that the electrical engineer reported that the new steam alternator, No. 6, had been started, and had run very satisfactorily for about 10 days on the town mains; the buildings were nearly complete, and he hoped to get the battery of accumulators into place shortly. He recommended that a small part of the extension to the arc lighting mains included in his estimate of extensions in February should be carried out, at a cost of about £120. In consequence of two faults on high pressure cables on Saturday evening, the 16th ult., the town supply was interrupted for periods of eight and 18 minutes respectively, at about 7.20 p.m. and 10.50 p.m. The earlier fault was due to breakdown of a rubber insulated cable forming a service in Lansdown Terrace, and the second fault occurred on one of the two main feeders and at the junction of the St. George's and Gloucester Roads. At this place the cable had been several times disturbed by openings made by the gas company, and the Highways and Waterworks Departments, and he thought it likely it had suffered some rough usage; the fault, however, was very much burnt up, and at that time he could give no definite opinion as to the cause of the trouble. Both faults had been repaired. The estimate of expenditure on street lighting for the current year was £3,750 for gas and £2,550 for electric lighting—total £6,300.

Chiswick.—The District Council last week passed the following resolution:—"That a statement of the dealings of the late District Council with the Bourne and Grant Electricity Supply Company, Limited, and a copy of the correspondence between the said parties, together with a copy of the agreement originally entered into, be supplied by the clerk to each member of the present Council and also to the public press, and that all necessary steps be at once taken to re-acquire the electric lighting power of the parish."

Conisborough.—The Parish Council will oppose the General Power Distributing Company's scheme.

Country House Lighting.—According to an Aberdeen paper, Mr. George Farquharson, of Whitehouse, has just utilised the water-power which has been hitherto running to waste on Donside for electric lighting purposes. A pipe conveys the water down the hillside to a turbine which drives the dynamo. Every part of the mansion house is lighted electrically, and the long winding avenue is also illuminated by lamps hung from the trees. During the day the current will be used for driving the threshing mill, corn-bruising machine, turnip and chaff cutters, &c. The turbine house is about 100 yards from the mansion house. The electrical work was carried out by Messrs. Middleton & Co. The dynamo was supplied by the Electric Construction Company, and the turbine by Messrs. W. Günther & Co.

Coventry.—The quarterly statement of the Corporation Electric Light Department shows a considerable advance upon the corresponding quarter last year. The amount of current supplied was 30,090 units, as compared with 21,516 during the same quarter last year. The rentals amounted to £891 4s. 5d., as compared with £547 6s. 5d., while the number of consumers increased from 76 to 112.

Clay Cross.—The District Council is considering the scheme of the General Power Distributing Company. There is a good deal of feeling in favour of the proposal, but the matter is to be investigated by the Highway and Lighting Committee.

Devonport.—An offer to provide the town with one of Willoughby's refuse destructors, capable of dealing with from 70 to 100 tons of refuse per day, has been referred to the Sanitary Committee, with the assistance of the Electric Lighting and Tramways Committee. If the destructor is approved, it could be purchased at the end of three months for £2,000.

Dundee.—The Town Council last week unanimously passed the recommendation advancing the salary of the borough electrical engineer, Mr. Tittensor, by £50 per annum. There was a general discussion in the Council, on the suggestion of the engineer that lamps should be placed in certain streets, and it was moved that the engineer should draw up a big scheme, embracing the central and principal streets of the town. It was stated by others that they had already had a big scheme from the engineer, which was delayed until the tramway question was settled. The proposals for lamps to be put up in certain streets were referred back to the Gas Committee.

The electricity rental during the past year came to £6,279 odd, an increase of £736 odd compared with the previous year.

Eton.—The District Council has appointed a Committee to obtain information *re* electric lighting from other towns.

Fulham.—We understand that at last week's Vestry meeting the Electric Lighting Committee recommended the appointment of Mr. F. H. Medhurst as consulting electrical engineer.

Germany.—The United States Consul at St. Gall, in a report to his Government, states, according to the *Board of Trade Journal*, that in the following cities in the German Empire the municipal authorities own and manage the electric works that supply light and power: Bremen, Barmen, Cassel, Darmstadt, Düsseldorf, Elberfeld, Hanover, Cologne, Königsburg, Lübeck, and Pforzheim. All of these cities, with the exception of Hanover, also own the gas works. The following cities have constructed the electric works for the purposes of light and power, but have leased the management of the same to private operators: Aix-la-Chapelle, Chemnitz, Frankfort, Strasburg, and Stuttgart, all of which, with the exception of Chemnitz, are cities where the gas works are under the management of private corporations. In the following cities, private companies have established electric works with the agreement that, under certain conditions, the municipal authorities shall have the privilege of securing absolute control and ownership by purchase: Altona, Dessau, Gera, Hagen, Heilbronn, Leipsic, Mülhausen, Stettin, and Zwickau. Of these cities, the gas works are under private control in Dessau, Hagen, Mülhausen, and Zwickau.

Glasgow.—The Electricity Committee last week generally approved of the report, mentioned in our last issue, recommending a large electric lighting scheme, involving half a million expenditure, for the municipal area.

Glossop.—The Town Council is engaging a Manchester engineer to report on an electric light scheme.

Godalming.—On Tuesday last week a Local Government Board inquiry was held with reference to the Council's application for a £1,500 electric lighting loan. Evidence as to the scheme was given by Mr. Cousins, electrical engineer, representing the firm of Kincaid, Waller & Manville, and the Mayor and other residents spoke in favour of electric lighting, and stated that the gas was at present bad, and much too dear. The town clerk explained that a station site had been purchased for £400 near the pumping station. The number of lamps within the compulsory area is 32.

Govan.—The Police Commissioners have adopted the recommendation of the Electric Lighting Sub-committee that steps be taken to put the electric lighting powers into force, and the matter has been referred back to the Committee to consider and advise as to system, site, and other details. It was considered that an electric supply undertaking was a municipal necessity.

Hampstead.—On Thursday night last week, for the first time, the lower part of Heath Street, with High Street and Haverstock Hill, were lighted with electric arc lamps. There will now be a straight continuous line of arc lamps from the fire station to Oxford Street.

Hastings.—The electric light machinery for the Corporation works at Waterworks Road is in working order, and the requisite one month's notice has been given to to the Hastings Electric Light Company of the desire of the Council to determine the existing agreement with the company for the lighting of the electric lamps on the front line. The Public Lighting Committee has reported to the Council that the Board of Trade had issued the provisional order authorising the supply of electricity by the Council. Section 3 of the order, providing that the order shall not come into force or have effect, notwithstanding the confirmation thereof by Parliament, until such date as the Board of Trade fix a date for the commencement of the order when they are satisfied that the Council has completed the purchase of the undertaking of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, in accordance with the agreements entered into by the Council with the company, and that as from the commencement of the order the orders previously granted to the company and to the Corporation shall be revoked. The necessary application has been made to the Local Government Board for the sanction to the borrowing of the money required for the purchase of the company's undertaking.

Hull.—There is a proposal to construct a subway, and the gas engineer has sunk a trial bore with a satisfactory result. It is suggested that the Waterworks and Electric Lighting Committees should lay their mains in the subway and take part in the cost (£4,000). The Council is to consider the matter.

Ilfracombe.—A Bill to confirm the Ilfracombe Provisional Order granted by the Board of Trade came before the Examiners of the House of Commons last week.

India.—The erection of the electric light at the Golden Temple, Amritsar, has been completed. There are altogether 16 lights put up round the sacred tank, and one large globe on the tower of Baba Atal. The Sikhs would not allow the interior of the temple to be lighted by electricity, on the ground that it would be contrary to the doctrine expounded by the Guru. The temple authorities have, however, secured two large chandeliers for the inside of the temple, and are waiting to see a change in the views of their co-religionists, especially the Kukas, in the hopes of having them fitted inside the temple later on. The cost of the whole is about Rs.60,000.

Ipswich.—The tenders for the installation of the electric light at the new Workhouse were to have been opened at the meeting of the Board of Guardians on Friday, but the clerk said that he had only received three, and he had heard something mentioned as to there having been a misunderstanding. No tender had come in from either of the local firms. It was decided to defer the consideration of the tenders for a week.

Isle of Wight.—At the last meeting of the Shanklin District Council the members deputed to discuss with the Sandown District Council the question of the lighting of the two districts by electricity, reported having met representatives of Sandown. It was then explained that Messrs. Edmundson were prepared to form a company for the supply of electric light within the districts. The company explained its terms *re* charging, time of purchase by the Corporation, &c. The estimated outlay was stated to be £25,000, including an anticipated 10 miles of mains. A draft agreement had been forwarded, but the matter was not discussed, the clerk being instructed to confer with the solicitor to the Board and a representative of the company.

Islington.—The report of the Electric Lighting Committee shows that during the quarter ending March 31st the Vestry has made a profit, after paying all its liabilities on capital account, of £1,753. The sale of the light is increasing by leaps and bounds. In the corresponding quarter of 1897 the number of units sold, including public lighting, was 132,044, which produced a revenue of £3,213, but in the last quarter the supply had gone up 99 per cent., the total units sold being 263,502, or an increase of 131,458. The revenue was £5,917, or an increase of £2,704. The working expenses in the March quarter of 1897 were £2,035, or nearly equal to 3⅝d. per unit. During last quarter the expenses of production were £2,668, or nearly equivalent to 2½d. per unit. Thus the working expense only increased 31 per cent., while the revenue increased by 84 per cent. The net profit in March, 1897, was only £147, and £1,205 gross. Now the gross profit is £3,326 and £1,753 net.

Leith.—On Wednesday last week Bailie Manclark, the convener of the Electric Lighting Committee took out the first shovelfull of earth at the foot of Leith Walk, and the laying of mains was proceeded with immediately.

Leyton.—A Local Government Board inquiry is to be held on 20th inst. *re* the Council's electric lighting extensions loan. The electrical engineer has reported as follows:—Units generated in March, 23,451; units sold, 14,506; maximum current, 390; lamps installed, 828; total lamps installed to March, 6,788·6; total applications to date (April 5th), 126; total customers connected to date (April 5th), 116; less customers disconnected, 4; net total, 112; largest number of lights on at any one moment, 3,900, being about 58·3 per cent. of the total connected. The tender of the General Electric Company for dynamos, for the sum of £647 16s. 6d. has been accepted, instead of that of Messrs. Siemens Bros. & Co., who could not undertake to deliver the dynamos until the expiration of eight instead of three months, as provided by the specification.

Lincoln.—In a few weeks the Corporation will commence to lay electric mains for the supply of electricity, and we understand that an arrangement has been made with the National Telephone Company to lay their underground cables at the same time, the company bearing the cost of the trenches, &c.

London.—The clerk to the St. Giles Board of Works reported at the last meeting that he had, with the surveyor, attended the inquiry held by the Board of Trade into the supply of electricity to the district, and they had been successful in all they had contended for. Mr. Doll: That is, in two years we are to have a competitive supply.

Long Eaton.—The Co-operative Society has asked the District Council for permission to take electric cables along the streets from the old gasworks to their property in Main Street. The subject stands deferred.

Lowestoft.—The Corporation is considering the advisability of providing electric light, and a provisional order has been obtained. One clause would have empowered the authority to supply electrical fittings and fixtures, but to this the Board of Trade objected. At a meeting on Monday, May 10th, the Council decided to press the Board for the retention of this clause, or a modification. It is intended to work the electric light in conjunction with the Horsfall destructor.

Ludlow.—The Town Council last week formally resolved, on the recommendation of the Lighting Committee, to give the £20 prize offered for the award of best electric lighting scheme to Mr. Enwright, of Kensington. The Committee were much disappointed to find that the mill power was not sufficient to drive an electric light plant. Of the 10 schemes received only two exclusively dealt with the water-power, and these in such a way as to interfere with the Waterworks power. They could not entertain a scheme which would interfere with the water supply. Mr. Enwright's scheme proposed to use gas for driving power. The idea was to erect a Dowson's patent gas apparatus to provide its own gas, and to lay down two engines of 54 horse-power, which would be sufficient to provide light for six or seven hours a day for the whole borough. It was proposed to erect the plant in the Cattle Market, with a main feeder to the Butter Cross, from whence the mains would be distributed. The total expenditure for this scheme was £5,000, the estimated annual cost to the Corporation was £650, and the estimated annual revenue £1,300, yielding a profit of £500 or £600 a year. Mr. Enwright also stated he would find a contractor to carry out the work at the figures named.

Luton.—Over three years ago the Council obtained an electric lighting provisional order, and has since obtained an extension of it for one year. An electrical engineer recently submitted a report on a scheme, and a deputation inspected systems in various places. A few days ago the party went to Brighton, and were shown round by Mr. Arthur Wright.

Malvern.—Messrs. C. Santler & Co. are lighting up the Arts and Industries Exhibition at Malvern from May 3rd to 10th at the Assembly Rooms. There are three arc lights of 1,000 H.P. each, and a number of incandescent lights on exhibition stalls of 8 and 16 C.P. each. There is no public electric lighting in Malvern.

Manchester.—At the monthly meeting of the Manchester Corporation on Wednesday last week, Alderman Higginbottom, in moving the adoption of the minutes of the committee, explained the circumstances under which he and the deputy chairman had been appointed to give evidence before the Special Joint Committee of the House of Lords regarding the supply of electrical energy by Corporations and others, and this was a matter which affected that Corporation and other authorities. The Joint Committee was appointed because of a difficulty that had arisen between Lord Morley, chairman of the Lord's Committee, and Sir Courtenay Boyle. The important principle was involved as to whether companies were to be allowed to compete with Corporations and other authorities within their own areas. If this were so, the Manchester Corporation would be placed in a serious position. The Manchester Tramways Company had a Bill before Parliament, and if the principle he had spoken of were granted, the company might have power not only to work the tram lines electrically, but also to compete with the Corporation in the supply of the electric light to consumers. He could not conceive that the Joint Committee would report in opposition to the interests of Corporations. If they did, the Corporation would have to take steps to be heard before Parliament in another matter. He could assure the Council that he, and those co-operating with him, had done their best to defeat a very wrong thing indeed. The estimate of the electricity department in Manchester for the current year amount, on expenditure account, to £7,000, the current for public lighting absorbing £1,500, and lamps and connections £5,500.

Monmouth.—The local papers are full of a report of last week's Council meeting, which lasted for three hours, the greater part of the time being passed in a discussion regarding remote points in the drainage and electric lighting scheme. The matter really seems to refer more to the drainage works than to the electric lighting affairs, there being some disagreement between the consulting engineer and one of the contractors; but wherein the electric lighting scheme is affected is the resignation of the chairman and another member of the Electric Lighting Committee, the former having been actively connected with the combined scheme all along.

Montrose.—The Asylum House Committee has had under consideration the renewal of the electric lighting plant of the main building of the institution. The report of Mr. Young, engineer, Glasgow, had been considered, and, on his suggestion, it was agreed that the type of engine should be the Belliss. After consultation with Mr. Young, it was agreed to accept the offer of Messrs. W. Dickson & Co., Glasgow, to carry out the installation, their offer being in every respect the lowest.

Morecambe.—In connection with the installation of electric light at Morecambe, tenders are invited for supplying a wrought-iron water tank, 5,000 gallons capacity, by Mr. C. F. Parkinson, the engineer. It was expected that the work would be completed for Whitsuntide, but it has been delayed, and will not be finished before the latter part of the season. When the front Promenade is first lighted is is intended to hold a *fête*, which will take the form of a "Battle of Flowers." The District Council some time ago took over the works of the private company.

Newcastle.—At last week's City Council meeting Mr. W. Smith presented the report of the special committee appointed to consider the desirability of the Corporation undertaking the provision of electricity, recommending that the committee be authorised to negotiate as to terms upon which the electric light companies will transfer their undertakings to the Corporation.

Ossett.—The Town Council has resolved to visit and inspect the electric lighting plant and refused estructor in Shoreditch, with a view to ascertaining the practicability of combining the two objects in Ossett.

Perth.—The Board of Trade have issued a provisional order to the Police Commissioners in connection with the electric lighting of the city.

The Police Commission has received a letter from the Mutual Electric Supply Company, Brighton, stating that if the Commissioners were disposed to delegate the powers under their provisional order for electric lighting, they were prepared to offer terms for consideration. The Commissioners have replied that they are not yet in a position to entertain a proposal, but that it would be considered at the proper time.

At the monthly meeting of the Police Commission on Monday, discussion took place regarding an account of £15 15s. tendered by Mr. Thomas Barton, Blackburn, for a report on the electric lighting scheme. The Lord Provost Dewar said Mr. Barton offered to come and give them the benefit of his advice, but it was on the understanding that they were not to be committed to him either for advice or in the appointment of an electrical engineer. The country, his Lordship continued, was swarming with gentlemen of this kind, who were willing to go here, there, and everywhere, to advise those interested in electric installations. They were in the position of gentlemen who had something to sell, and they meant to take the opportunity of selling it. The Corporation paid Mr. Barton's expenses, and it was on the distinct understanding that there would be no other claim that Mr. Barton was allowed to give advice at all. One or two other gentlemen had been employed on the same terms, and it would be a dangerous precedent to admit this claim, even to the extent of five guineas, as was proposed. He objected to paying every gentleman who volunteered his services to the Commission. It was agreed to deny liability.

Peterborough.—The local company which was hoping to undertake the electric lighting of Peterborough in the event of the Local Government Board persisting in its refusal of the application of the Town Council for raising a loan, is, of course, disappointed at the Board's last step in granting powers to the municipality. The Peterborough Electric Lighting and Power Company seems to think that the Board will neither revoke its order nor grant the application, yet it is considered that the Board would not allow two orders to be worked, as the area is not large enough to justify that step.

Plymouth.—At the meeting of the Town Council on Monday there was an animated debate previous to agreeing to the large increase in the rates, *i.e.*, 11d. in the £. Naturally the electric lighting and traction scheme came in for some criticism. Mr. Bellamy, one of Plymouth's foremost men, and who is connected with the gas company, agreed that the town was badly lighted, and that something should be done. But with gas at 1s. 9d. the 1,000—the cheapest in England—that was, he considered, not a town to go in for a luxury like electric light. He believed there would be a loss on the electric light and work generally of £1,500 a year.

Poplar.—The following took place at a recent meeting of the District Board of Works, and is reported in a Whitechapel paper:—The County of London Brush Provincial and Electric Light Company wrote asking for the name of the member who accused the company of "touting" for the company, and saying that unless it were given proceedings in another quarter would be taken. Mr. Marks: Who was the letter addressed to? The clerk replied that the first letter was addressed to himself, and it appeared to be a personal application to him, because the letter said, "I shall be glad to hear from you." Mr. Marks: Then the letter is a private one, and we have nothing to do with it. The clerk explained that he had placed the letters before a special committee, who would have nothing to do with the matter. Mr. J. R. Smith: I shall move that the communications be laid on the table. Mr. Purdy seconded the motion, which was unanimously agreed to.

Rathmines.—Mr. Robert Hammond is to furnish a supplemental report on his proposed scheme for lighting the town electrically. The secretary of the Electric Light Committee has reported having taken legal advice as to the extent of the obligation thrown on the Tramway Company by the 15th section of the Electric Power Act, 1897, to light the road, and Mr. Fitzgerald is of opinion that that section required the company, where pillars are erected in the centre of the road, to light the whole width of the road to the satisfaction of the local authority.

Sheffield.—There is a proposal before the City Council to appoint a Special Committee to take into consideration the desirability or otherwise of proceeding further with the separate electric power station, seeing now that the Corporation are owners of the present electric station, where there is sufficient room to put all that is required for the tramways for a considerable time to come, and, in the meantime, to make full investigation into how far the waste heat of all the destructors and water-power might be used in the future for generating electricity, and report.

The Parliamentary Committee has expressed its approval of the steps taken by the town clerk in conjunction with the representatives of other towns in the district to oppose the Bill of the General Power

Distributing Company, and also with reference to the Joint Committee of Inquiry which has just been considering electrical matters in London.

Shoreditch.—On 5th inst. the Electric Lighting Committee issued its first report, showing the results of the first nine months' working. There is stated to be a profit of £2,063 0s. 4d.

St. Pancras.—At the meeting on Wednesday the Vestry resolved to reduce the charge for current for public street lighting from 5d. to 4d. per unit, the alteration to come into force on July 1st. It was also decided, commencing on the same date, to reduce the charge to private consumers to 6d. per unit for the first 1½ hours' daily consumption, and to 3d. per unit for all current used afterwards. The Vestry sanctioned an expenditure of £790 for additional condensing plant for the King's Road station. The Elieson Lamina Accumulator Company, 4, Greenland Place, N.W., has consented to lend the Vestry a motor dust van on trial, provided that the local authority would supply the current for charging purposes free of expense. The Dust Committee has accepted the offer.

Swinton.—Last week a meeting of ratepayers and owners resolved to oppose the General Power Distributing Company's scheme.

Teignmouth.—The Gas Committee of the District Council recommends that information be obtained showing the probable cost of a provisional order for lighting the town by electricity.

West Hartlepool.—Tenders are shortly to be invited for the erection of the lighting station. The Sub-committee has submitted its report to the Corporation on dust destructors. After visiting Bradford, Oldham, Shoreditch, Leyton and St. Luke's (London), it is recommended that a six-cell destructor be obtained for West Hartlepool at a cost of about £5,000 or £6,000.

Westgate-on-Sea.—A Board of Trade inquiry will be held by Major Cardew to-day (Friday) in the matter of the Isle of Thanet District Council's application for a provisional order.

Wick.—The Harbour Trust had recently under discussion a proposal to light the harbour with electricity, the motive power to be derived from an overflow stream which falls into the outer basin. Owing to shortness of funds the proposal is to be held in abeyance in the meantime.

Wigan.—Circulars were recently issued to ratepayers *re* electric lighting; 69 were in favour of an installation being laid down, and 61 undertook to use the current. 85 were not in favour of an installation, and did not undertake to use the current. 29 were in favour of an installation, but would not undertake to use the current, and 69 gave a provisional undertaking. The Gas and Electric Lighting Committee recommended the Town Council to appoint a sub-committee to make inquiries into the subject of electricity generally, and for that purpose to visit six towns where public electric lighting has been established. This resolution was the subject of a discussion at the monthly meeting of the Council on Wednesday last week. Mr. Laycock said he desired to take exception to the resolution which was passed at the meeting of the Gas and Electric Lighting Committee the previous day. He failed to see the advisability of appointing another Sub-committee. They all remembered that in March of 1894 a Sub-committee, consisting of 14 members, was appointed. They had practically a roving commission given to them to make inquiries all over the country, and he was inclined to think they even went out of the country to get information upon that matter. At the end they issued a report, and they advertised and succeeded in getting tenders for the laying down of plant, but although they had got much information, and spent, he believed he was right in saying hundreds of pounds of ratepayers' money in getting that information, yet they did not recommend whether the high or low tension should be adopted in Wigan. Even in asking for tenders they left it for the electrical engineers to say whether they would recommend high or low tension. He thought that was purely an engineering and a technical matter, and he thought the better course to adopt would be to get the opinion of an expert before they appointed another committee. An expert would recommend a proper system, and give them places where it had been adopted, and the Committee would be able to recommend the Council to adopt a particular course. To give the Committee power to roam about as the other Committee did would be a waste of money. Mr. Ashton said that the minute was put on the book to get the feeling of the Council as to whether they were in favour of the electric light or not. Personally, he thought it ought to go forward in Wigan. After further discussion the minute was withdrawn.

Wimbledon.—At last week's District Council meeting Mr. A. H. Preece submitted his report and plans on the question of the combination of the refuse destructor in the boiler house of the electric light works. The total estimated expense was £4,650. Mr. Preece was extremely anxious that the interest and sinking fund of the destructor should be kept distinct from the electric lighting accounts. The electric lighting undertaking should also be paid at least 1s. per ton if it was to undertake the working of the destructor. The Council resolved to apply to the Local Government Board for sanction to a loan of £5,000. A number of tenders were recently obtained by the surveyor from certain firms for the electric wiring of the depôt buildings in Queen's Road, but the Council has resolved to return these tenders, and advertise generally for estimates. The cost is about £150.

Wolverhampton.—At Monday's meeting of the Town Council the Lighting Committee presented a report, in which they proposed to make a reduction in the average number of hours per day during which the maximum demand is to be used from 2 hours to 1½ hours. The Committee recommended "That as and from July 1st, 1898, the price for energy for lighting purposes be fixed at 6d. per unit, on a maximum demand of an average of 1½ hours per day, and 3d. per unit for all energy consumed in excess." The Council adopted the resolution.

Worcester.—Mr. Ruthven Murray, the borough electrical engineer, has, in accordance with the instructions of the Council, issued his report upon the working of the generating station for the past year, dealing with the various matters in the abstract of accounts issued by the committee some months ago. He calculates, says a local paper, the additional cost for coal, by reason of extra cartage to the works, at £127 on the 1,702 tons consumed in the 12 months, and he points out that this represents 6 per cent. on £2,100. He estimates the revenue derived from water-power at £1,880. Dealing with the question of the charge to be made to consumers, he says: "The lowness of the average price obtained is not proof that we are supplying under cost, as has been urged, since, whether a profit or loss is made depends entirely on the length of time the supply is used or the number of units consumed per maximum lamp demanded. The units sold at 6d. cost 8d. and upwards, whilst those sold at 2½d. cost under ⅞d. I am strongly in favour of an alteration in price, but such alteration must be to charge the short hour user somewhere nearer the cost of the supply, so that the loss incurred on such shall not be borne by the profitable consumer, as is now the case." He proceeds, also, to explain how so great a loss as 25 per cent. of the current generated is occasioned, viz., by the performance of work in the system, either by magnetising iron in transformers or meters so as to increase the sensitiveness in registering a very small proportion of their full load current, or in overcoming the resistance to the transmission of energy in the mains or other conductors. The lost power generated by water represents 55·26 and by steam 44·74. Of the total power generated during 1897, water-power represented 46·60 against steam 53·40.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Belfast.—It will be remembered that the Tramway Company has informed the Corporation that it cannot establish electric traction upon its lines unless its lease is extended. Last week there was a proposal before the Corporation to make the Law and Electric Committees into a Special Committee with a view to inquiring into the whole question, but after a lengthy discussion the matter fell through, the meeting being counted out before a vote was taken.

Birkenhead.—The report of the Special Tramways Committee, which we gave briefly last week, was adopted by the Town Council on 4th inst., without binding itself to the detail of the routes suggested. In the discussion upon the report there was some opposition, and it was urged that having regard to the contemplated outlay, namely £200,000, the matter should be dealt with by a full meeting of the Council, whereas only about half the members were present at the meeting. However, the report was adopted by a large majority.

Birmingham.—The old tramway controversy is agitating the minds of the City Councillors, who, it will be remembered, blocked the way for enterprise by declining to allow the Tramway Company to use the overhead trolley system. Mr. Ross's statement, which appeared in our "City Notes" last week, to the effect that the company at one stage of the negotiations received permission to use the trolley system, is denied by members of the Council, and the Town Clerk is communicating with Mr. Ross on the subject.

Dublin.—The Clontarf and Hill of Howth Tramroad Bill was before a Select Committee of the House of Lords last week. The tramway will run along the foreshore of Dublin Bay and terminate at Howth. It will form a connection with the tramways of the Dublin United Tramways Company, which are worked by electric power. The overhead electric trolley system is proposed. Mr. Fraser, M.I.C.E., engineer to the scheme, gave evidence.

The Dublin Southern District Tramways Bill in relation to the speed allowed on their lines was before a Select Committee of the House of Commons last week.

The Drumcondra Commissioners have decided that the Dublin United Tramways Company be charged wayleave for being allowed permission to run electric trams through the township, first payment to commence at the end of 10 years from the obtaining the order from the Privy Council, and the amount to be paid to be then arranged by arbitration between the Town Commissioners and the company, the line of rails to be placed on the centre of the road, and the extension to be completed within five years.

The Kingstown Commissioners are endeavouring to induce the Dublin United Tramways Company to undo some of the damage to the township, which the Southern Districts Company, with the full assent of the same Commissioners, inflicted. The company, according to *Freeman's Journal*, is proving amenable, and in its own interests. For if the double lined tramway has added enormously to the difficulties of business men in the main thoroughfare of Kingstown, the delays of the cars in getting through have detracted very seriously from the attractions of the tramway service.

Dudley.—At last week's Council meeting the mayor, moving the adoption of the report of the Railway, Tramway, and Electric Lighting Committee, remarked that in the matter of the proposed tramway to Cradley Heath they wished to work harmoniously with the Rowley Regis District Council. If the Rowley authority would not construct a line in their district and would give Dudley the power the latter would do it. The Rowley people, however, had decided to do it themselves. A report is being drawn up of the deputation's visit to the Worcester Electricity Works.

Dudley-Stourbridge.—Last week an active start was made with the alteration of the permanent way to permit of the introduction of electric traction. The rolling stock is being made as quickly as possible, so as to effect an early completion of the undertaking.

Dundee.—The Coporation Tramway Bill under which power is sought to work the lines in Dundee and district, was before a Select Committee of the House of Lords last week.

Ealing.—Various electric tramway matters were under consideration at last week's District Council meeting. There was a letter from the Simplex Electric Traction (Conduit) Company, setting out the advantages of the company's system of electric traction for tramways, and inviting the Council to see it in operation at Prescott, and also a communication from another firm anxious to acquaint the Council with the merits of its electric traction apparatus. The scheme of the London United Tramways Company was discussed, and the voting was 7 in favour of the following resolution and 8 against:—"That this Council withdraw its opposition to the London United Tramways Bill, subject to terms and conditions being arranged, and that Mr. Clifton Robinson be requested to meet the Council in committee with the view to the adjustment of such terms and conditions." The motion was accordingly lost. One member and the chairman did not vote.

Electric Power Schemes.—The Notts and Midland Traders' Association has passed a resolution expressing the opinion that it is desirable to encourage the introduction of electrical power into the towns and villages of Nottinghamshire, Derbyshire, and district, as it would prove of the utmost practical utility in aiding agriculture, village trades, and general manufactory purposes. This was in connection with the General Power Distributing Company's scheme.

Glasgow.—The Tramway Committee recommended, and it has been approved, that it be remitted to the sub-committee on the Springburn route to make arrangements to have poles, &c., put up on the High Street line, at present being constructed, and which had unusually steep gradients, so that it might be worked with electric power in connection with the Springburn line.

Grimsby.—The tramway track is out of repair in some places, and the company is delaying remedying the defects in view of the probable adoption of electric traction very shortly. The Highways Committee, however, has requested that the lines be put into repair at once.

Hastings.—The scheme of the Hastings, Bexhill, and District Light Railways (Electric) Company is to be again considered by the Town Council. The Council's own scheme was not passed by the necessary two-thirds majority, hence the re-opening of the negotiations with the company. Mr. Murphy will attend a special meeting of the Council to confer *re* the company's proposals.

Italy.—It is reported that Messrs. Siemens & Halske, of Berlin, have submitted to the municipal authorities of Alessandra and Valenza a proposal to construct an electric railway between the two towns, a distance of about 40 kilometres. It is proposed to utilise the water-power of the river Po in the generation of the necessary electrical energy.

Johnstone.—The British Electric Traction Company have lodged an application with the Town Council soliciting their approval of their scheme for constructing a tramway in the burgh connecting with Paisley. The application raised a lively discussion at the monthly Council meeting. The Council wants further information of the scheme.

Kidderminster-Stourport.—Successful trial runs were made over this electric line on Tuesday and Thursday last week. Tuesday's trial was merely to test the accuracy of the gauge, but on Thursday electric power was used. The official inspection is fixed for Monday next, May 16th.

Leeds.—The question of providing electric cars on the Wortley route was considered at a meeting of the Leeds Highway Sub-committee on 9th inst. A deputation presented a petition signed by about 400 ratepayers, entering an emphatic protest against the decision to extend the electric system of traction to the four routes mentioned, to the exclusion of Armley and Wortley. The objection which the committee have to deal with on the Wortley route is that the cars would have to be turned in Boar Lane, a proceeding which would cause considerable inconvenience to the traffic in one of the most crowded thoroughfares of the city. Some means of overcoming this difficulty, it was said, must be found before the electric system can be extended to Armley and Wortley. The committee, however, agreed that it was desirable that the system should be extended to the Wortley route at an early date, and will probably deal with the question as soon as the work upon which they are entering is completed. Dr. Hopkinson was again appointed consulting electrician in connection with the extensions, and was instructed to prepare plans and specifications for the four routes decided upon, and to submit them to the committee when ready.

Liverpool.—It seems that Sir Arthur B. Forwood has actually severed his connection, not only with the Tramways Committee but with the City Council. The circumstances which led to this were briefly stated in our last issue.

London to Oxford.—The *Financial News* says:—"The Light Railways Act possesses possibilities to which commercial men are waking up. We are told of a dream of England one vast network of tramways. It will probably remain a dream; for the world has not leisure to travel slowly nowadays. But there is talk of a scheme more practicable—the establishment of a road tramway from London to Oxford. It is not hoped to secure much through traffic, but to link the towns and villages together in one whole, and thus to develop local traffic. We presume that electric traction will be aimed at, and that the overhead wire is deemed the best system. That gives a rather appalling idea of what rural England may become in time."

Manchester.—The recent conference which took place last week between the Manchester Corporation and representatives of the local authorities interested in the tramway service failed to bring about a satisfactory arrangement in view of the expiration of the Carriage Company's lease, the Tramways Committee of the City Council have, according to the *Manchester Guardian*, reconsidered the subject, and now submit the following scheme, subject to Parliamentary sanction:—1. The several authorities outside the city shall, at their own cost, acquire and place the lines in their respective districts in a condition suitable for electric traction. 2. The several local authorities shall, either by themselves or by arrangement with the Electricity Committee of the Corporation or other local authority, provide electric energy and necessary equipment for the working of the tramways in their districts on the same system and at the same voltage as proposed to be adopted in Manchester. 3. Each authority shall fix the fare in its own district, and the same shall be placed to the credit of such authority. 4. Each authority shall be debited with the following and such other charges, not included under these headings, as may be incurred in the working and management of the tramways in the districts of such authority, all such charges to be ascertained on the car mileage principle:—(*a*) Traffic expenses; (*b*) management expenses; (*c*) repairs and maintenance of car sheds, workshops, &c; (*d*) repairs, maintenance, and renewals of rolling stock; (*e*) interest on capital expended on rolling stock, car sheds, workshops, &c.; (*f*) sinking fund in respect of same; (*g*) depreciation in respect of same; (*h*) electric energy in cases where the Electricity Committee of Manchester Corporation supply the same; (*i*) a charge of 5 per cent. on the total working expenses incurred by the Corporation under the above-mentioned items, exclusive of electric energy. 5. The net receipts in each district after deductions as above indicated to be handed over to the local authority. 6. The repair and maintenance of the permanent way in each district shall be undertaken by the local authority at their own cost. 7. This arrangement to be subject to revision at the end of three years' working. These terms are receiving consideration from the local authorities.

A conference took place in Manchester on Tuesday between the Manchester Corporation and representatives of local authorities interested *re* the suggestions made by the Manchester Tramways Committee. After discussing the matter in all its bearings, the various representatives failed to arrive at an agreement, and it therefore remains in abeyance. The Manchester Corporation, have, however, intimated their intention not to renew the lease with the Manchester Carriage and Tramways Company unless horse traction is abolished.

Middlesbrough-Stockton.—Work is stated to be so far advanced on the electric tramways that a trial trip is to be made in a day or two, and the lines may be opened by Whitsun week. The cables are laid and there are at the depôt 8 or 9 cars each to carry 60 passengers. The engines are being put in position in the power house. The car shed is almost completed and the battery room is progressing. A model truck in wood has been tried over a part of the track.

Norwich.—The promoters of the Norwich Electric Tramway Bill came before the Examiners of the House of Commons the other day for proof of compliance with the standing orders in regard to certain additions which it is proposed to make to the Bill as originally introduced. The necessary notices had not been given in time, so the Examiner decided that the Standing Orders had not been complied with. The matter is accordingly referred to the Standing Orders Committee.

Queenborough.—The promoters of the Sheppey Light Railway which is to be constructed at a cost of £52,000, in order to bring Sheerness into touch with Minster, have received notification that the Light Railway Commissioners will recommend the Board of Trade to issue an order empowering the construction of the proposed line from Queenborough to Leysdown.

Rochester and Chatham.—Although the inhabitants of Rochester and Chatham are naturally disappointed with the decision of the Light Railway Commissioners as to the proposal to introduce a system throughout the district of electric trams, still it is consoling to know that, after all, a very useful part of the scheme will yet most likely be carried out, as the whole scheme has not yet been set on one side by the Commissioners.

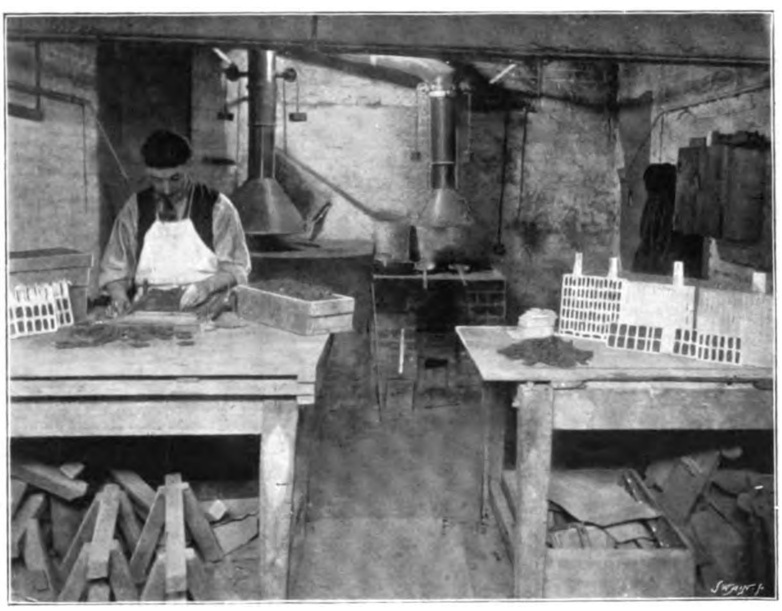
(*Continued on page* 661.)

THE MAKING OF LITHANODE ACCUMULATORS.

It will probably form an interesting addition to the series of articles on the manufacture of accumulators if we give some account of the process of making Lithanode cells. The company which is now associated with this type of battery is the Lithanode Electric Storage Company, Limited, which was formed some two years ago to acquire and work the rights and patents appertaining to the manufacture of lithanode accumulators. It is hardly necessary to say that the original application of lithanode for secondary battery purposes was due to Mr. Desmond FitzGerald, and his patents, as well as those of Mr. J. T. Niblett, are now vested in the Lithanode Electric Storage Company. The following description of the construction of this cell is taken from Mr. Niblett's recent paper :—

Making Lithanode Paste.

"Lithanode is not compressed peroxide of lead, as is sometimes supposed; for, however strongly this lead peroxide may be compressed, the resulting mass will disintegrate when immersed in a liquid electrolyte. It is produced from litharge made into a pasty mass with a solution of sulphate of ammonia, which causes the material to 'set,' so that it will no longer disintegrate when placed in a fluid. The 'forming,' according to the original idea, was performed in a bath of sulphate of magnesia. In ordinary practice the elements are made up of a number of small slabs of lithanode, whose outer edges are V-shaped. These slabs or pellets are arranged in a casting mould of any suitable dimensions, and are placed at such a distance apart and from the edges of the casting frame as to allow of sufficient space for the requisite quantity of metal to run in and impart adequate mechanical strength to the completed element. After the pellets have been arranged in this manner, an alloy of lead and antimony is run into the interstices, and thus a complete plate is formed.



Casting Frames.

"Before being cast up the positive pellets are converted into peroxide of lead in a forming bath; those for the negative plate are simply dried and cast up direct, the lithanode in the latter case being reduced to a condition of spongy lead by the ordinary electrolytic method.

"Where lightness is a desideratum, as in the case of a traction cell, the pellets in the positive plates are made larger, while the negative plate is constructed of lead gauze, having its outer edge strengthened by a rim of lead. The gauze is filled in with the prepared litharge which entangles itself in the thin lead wire, and thus produces a plate of great lightness, and one little liable to fall to pieces.

"Lithanode may be obtained in varying degrees of porosity. For high discharges it is made of a highly porous nature, the porosity being produced by incorporating in the material crystals of some salt, which is practically inert, and which is dissolved out during the forming operation.

"The rate of discharge obtainable from lithanode batteries varies between very wide limits, and is regulated by the character of the lithanode, whether made hard, medium, or soft. The ordinary working rate of discharge is $\frac{1}{14}$th of an ampere per square inch of lithanode plate, but owing to recent improvements very much higher rates of discharge can be obtained. The electrical capacity of lithanode, when discharged at the above rate, is almost exactly 1 ampere-hour per ounce, so that in a lithanode element weighing 1 lb. a current capacity of 16 ampere-hours is obtained. In practice, however, this high capacity is never reached."

It is generally thought that the chief direction in which lithanode has been applied is in small and portable forms of batteries; while, of course, a great measure of success has been achieved by the company in the manufacture of the smaller class of cell, this is by no means the limit of the company's operations, because lithanode cells have been made for purposes demanding heavy outputs. An instance of the company's work in the way of large batteries is one of 240 cells, which was supplied some time ago for Vera Cruz, this being probably the first storage battery ever erected in Mexico. This battery is employed in the town lighting of Vera Cruz, and reliance is placed on it both for lighting and power purposes.

We have already alluded to the success achieved in exploiting lithanode cells for small work. X ray operation for surgical and hospital work has called for a reliable and compact secondary battery, and the Lithanode Company seems to have created a great reputation in this direction, and both in this country and on the Continent great use has

F

been made of the lithanode cell for this class of work. Among medical men the productions of this company are held in great repute, and their accumulators are being used not only in cautery work but also for driving small motors such as are used in dentistry and surgical work.

We have quite recently had an opportunity of witnessing some of the operations necessary in making lithanode batteries at the works of the company, situate at Mann Street, Bermondsey, where a large factory has been completely remodelled for the manufacture of accumulators.

Fitters' Shop.

The basement of the building is given up to the pasting of plates, the casting of the grids or frames, the forming of the plates; and here is also the drying rooms. One of the series of illustrations which are here reproduced, shows the operation of making up litharge into a paste. The operator takes the dry powdered litharge and reduces it to the required pasty condition, by means of sulphate of ammonia; the next operation is to shape the material into

Lead Burning.

slabs or pellets as required, which are then taken to the drying rooms, where they remain till sufficiently dry and hard for treatment. Following the course of the pellets a little further, we find that those destined for the positive plates are placed in a forming bath to be converted into peroxide of lead, lithanode, of course, forming the basis of both positive and negative plates, but the pellets for the negative plates are dried and cast up direct. In the casting operation, of which an illustration is given, the operator arranges the pellets on the lower half of a mould, and after closing it pours molten metal round, the pellets, as we have before observed, being placed at a slight distance apart in order to permit the metal setting round.

The process of forming employed needs no special remark, it being the usual electrical one. In order, however, that the forming action be continuous without running plant at night, a battery of accumulators is employed which continues the formation process after the machinery has been shut down. The ground floor is devoted mainly to lead burning and fitting the plates together.

One of the illustrations shows the process of burning a set of plates together. The next floor is set apart as a fitters' shop, and here are made all the fittings necessary for the portable lamps. Then there are the carpenters' shop, the theatrical department of which we shall have more to say subsequently, and what is termed the sealing-in shop. When the batteries are assembled, they are taken to the sealing-in shop, and there sealed in and filled up ready for charging purposes.

Electrical power is obtained on the premises from a Crompton dynamo, which is driven by a horizontal steam engine, and in addition there is the storage battery, to which allusion has been made.

The following information concerning one of the lithanode cells has been used before, but it may be interesting to reproduce it here:—

Data of Complete 30 Ampere-hour Lithanode Batteries, including Wood Cases.

No. of cells.	Outside dimensions of battery.			Open E.M.F. of battery.	Approximate gross weight of battery.
	Length.	Width.	Height.		
	Inches.	Inches.	Inches.	Volts.	Lbs.

Detailed Particulars of Cell.

Vulcanite containing cell ... ... { 6·25 inches long. 2·12 " wide. 5·25 " high. weight, 10 ozs.

Positive element ...	Two plates in each cell, 5·9 inches long. 3·9 „ wide. 0·25 inch thick. weight, 1 lb. 1½ ozs.
Negative elements ...	Three plates in each cell, 5·9 inches long. 3·9 „ wide. 0·13 inch thick. weight, 11½ ozs.

Weight of connectors, 3 ozs.
Weight of cover, vent plug, sealing, and separators, 2 ozs.
Quantity of electrolyte, 15·5 fluid ozs.
Gross weight of complete cell, 6 lbs. 7 ozs.
Normal charging rate, 3 amperes.
Normal discharging rate, 3 to 4 amperes.
Maximum safe discharging rate, 9 to 12 amperes.
Approximate internal resistance, 0·015 ohm.

In adapting electric lighting to the many and varied requirements of theatrical work, the Lithanode Company have had unique experience, not only in supplying accumulators, but in devising special theatrical effects. We have before alluded in these columns to the different theatrical productions with which this company and its predecessors were associated. To instance the wide field covered in this direction, we might mention that during the last Pantomime season the Lithanode Company, in addition to provincial work, were associated with no less than seven in London, among them being those at Drury Lane, Brittania, Hoxton, and Standard Theatres. Of the effects created at Drury Lane and the Brittania, we can give personal testimony, and it is no exaggeration to say that the electrical portion of each entertainment was probably the most striking and attractive feature.

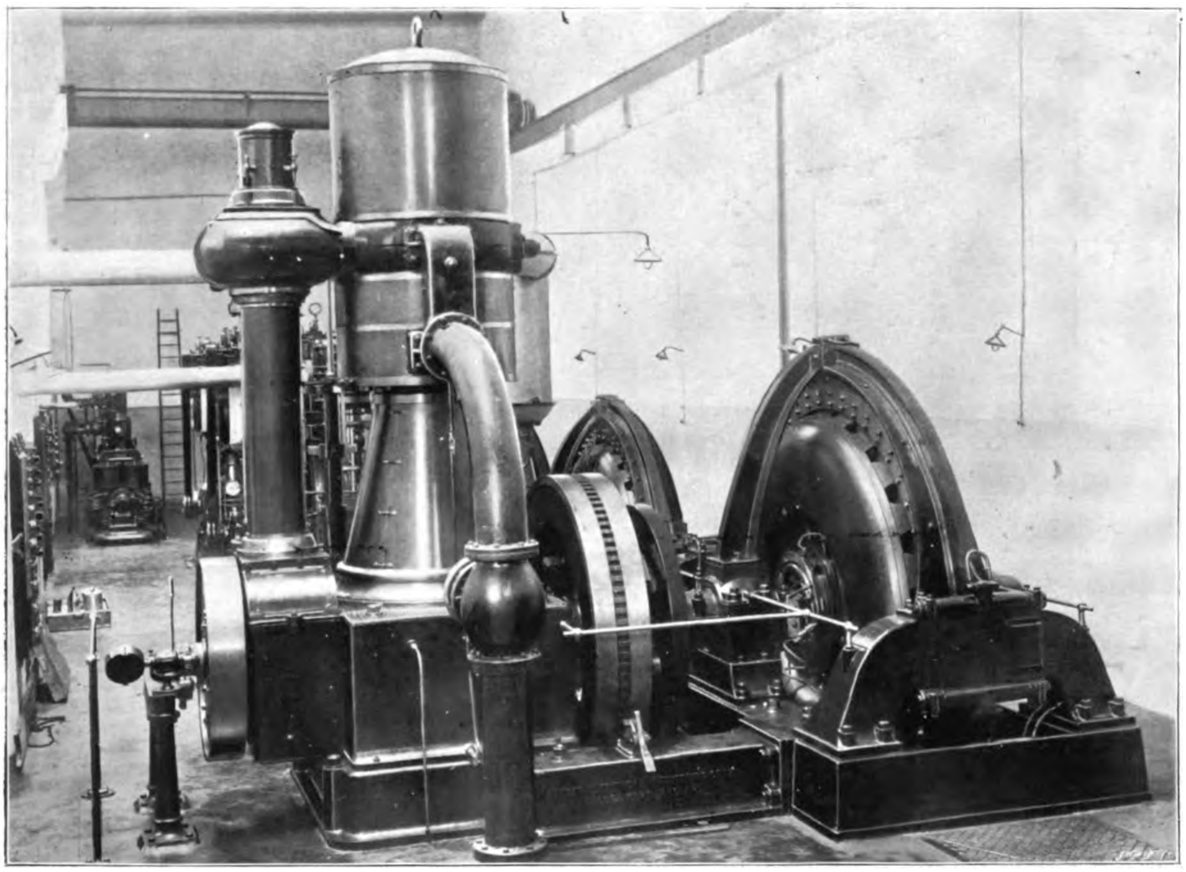
EXTENSION OF THE MALTA LIGHTING SYSTEM.

With a view to extending the electric light in Malta, a 200 kw. plant consisting of a Mordey alternator and Universal single-crank engine has recently been installed by the Brush Electrical Engineering Company. The illustration shows the plant in position. The installing of this unit raises the capacity of the station to 575 kw., disposed as follows:—one 200-kw., three 100-kw., one 50-kw., and one 25-kw. A 200-H.P. boiler of the Babcock-Wilcox type has also been erected, making a total of four boilers, all of the same capacity.

The station, which has been already described in the Review, has been running a little over 16 months, and started from the first with a paying load.

The streets of five towns, including the capital Valetta, are lighted with incandescent lamps of 32 C.P. About 65 arcs of the B.V. type are used for lighting the Grand Harbour and some of the principal thoroughfares in Valetta. These lamps have their own transformers, lowering the voltage from 2,000 to 35. The lighting on this system has given every satisfaction. The above represents about 150 kw. of load for street lighting, which is practically maintained the whole night through.

Beyond this, nearly the whole of the War Department buildings and barracks of these towns are connected on to the mains, being equivalent to about 2,500 8-C.P. lamps.



The Extension at Malta.

These lamps are alight practically the whole evening, till 10.15 p.m., when they come off simultaneously. There have been numerous applications for private consumption, and, now that the new plant is ready, they will be considered, all wiring being carried out by the Maltese Government.

A further extension, to a town called Sliema, will be carried out this year, about four miles away. The streets here will be lighted with incandescent lamps, with a few arcs along the sea front. Several of the forts and barracks at this place will no doubt be installed with the electric light. The price charged for current for lighting is 6d. per unit.

BASTIAN'S ELECTROLYTIC METER.

Mr. C. O. Bastian is probably, in the minds of many, mostly associated with the penny-in-the-slot meter; but he has lately completed arrangements with the Penny-in-the-Slot Electric Supply Syndicate, Limited, for the manufacture of an electrolytic meter, which has some very distinguishing features. The whole subject of electrolytic meters will doubtless be discussed after Mr. Gibbings's paper, which deals in a great measure with Mr. Bastian's meter.

The question of meters that will register small currents with accuracy is an important one to electric lighting systems, but the matter of initial cost of a meter is equally important. It is obvious, however, that there is little prospect of either the motor or clock type of meter being produced at a much lower cost than at present obtains, and it would seem that one must look in other directions to find a cheap means of registering small currents.

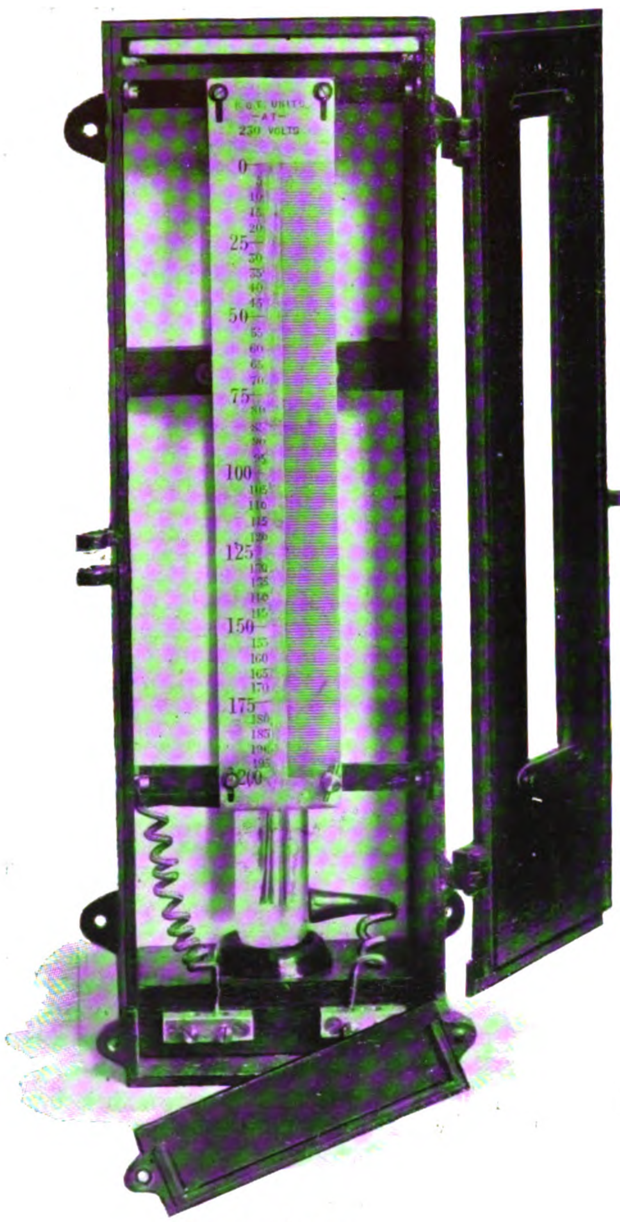
Not long ago we should imagine that the suggestion of using an electrolytic meter to surmount these difficulties would have been regarded only in the light of a last resource, but the Bastian meter is claimed to be sucha distinct advance on all previous electrolytic meters, that there is probably little reason to doubt that it will meet many of the requirements of both central station engineer and consumer.

Mr. Bastian has designed something new in electrolytic meters, which is not only said to be an accurate instrument for measuring small currents, but one which will probably cost half that of the ordinary meters on the market. The most notable electrolytic meter that has been used on supply circuits is that of Edison, the principle of which was that the current passing through a solution deposited metal at a certain definite rate, but the trouble that arose in weighing the plates and figuring out the current used, soon rendered it unsuitable for extensive systems. The direction in which the Bastian meter constitutes a departure from other electrolytic instruments may be obtained from the following details :—

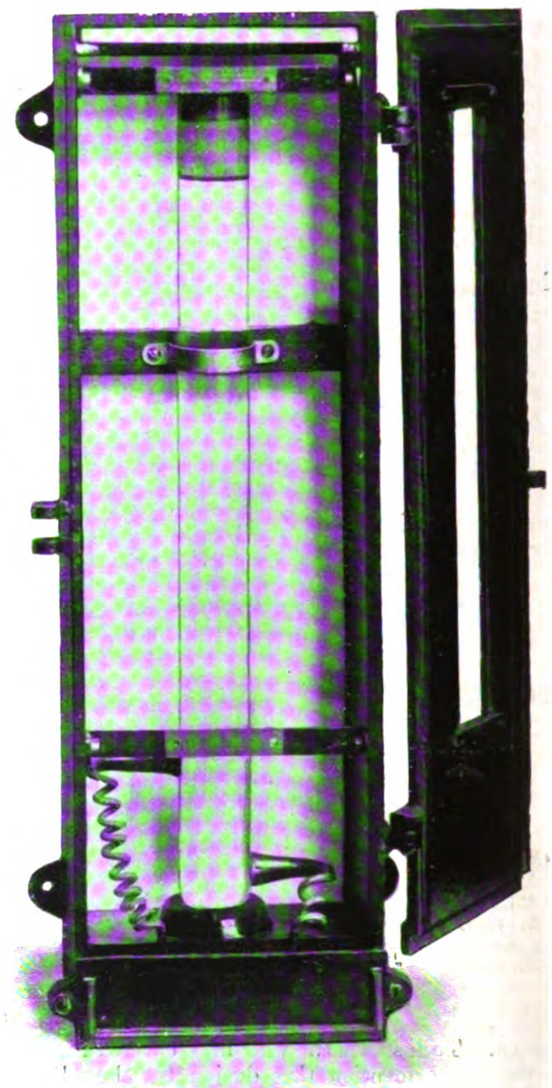
The main feature of the instrument is the registration of an electric current by means of electrolysis. The passage of an electric current through a dilute solution of sulphuric acid decomposes the liquid, and the difference in level is a measure of the current that has passed through.

The apparatus consists of a glass tube, at the bottom of which platinum foil electrodes are placed. The lower end of the tube is sealed, the top being open for the purposes of refilling with water and permitting the escape of the gases. In order to prevent ordinary atmospheric evaporation, a thin film of oil is poured on the top of the liquid.

The liquid is composed chiefly of water, rendered non-freezing to within 24° F. below the freezing point of ordinary water by the addition of sulphuric acid, upon which, however, the electric current has no appreciable effect.



Complete Meter.



Meter with Scale Removed.

It will be seen from the illustrations that the terminals of the electrolytic apparatus are in permanent connection to two other main terminals, which are mounted on a porcelain or ebonite block at the base of the meter. The whole apparatus is placed in a cast-iron case, which is fitted with a hinged door and a terminal door, which are provided with sealing arrangements.

The reading scale, which is marked directly in B.T. units, is placed in front of the tube, and is made of zinc or aluminium. It is so arranged that it can be adjusted to the extent of three-eighths of an inch up or down through the agency of an adjusting nut and thread at the lower end. This adjustment is provided in order to give an accurate zero when the tube is refilled with the electrolyte; it also precludes the necessity of extreme care when refilling.

The action of the meter decomposes the water, consequently, water only need be used when refilling the meter, for which purpose a very convenient form of funnel is provided by the makers. The necessity for refilling even the smallest meters does not arise until 200 B.T. units have been consumed.

It is interesting to examine the method followed in calibrating the instrument. As such a small amount of water is decomposed during the passage of 1 B.T. unit, it follows that a slight miscalculation as regards the bore of the glass tube might lead to a serious error, were the bore of the tube (as measured by calipers) taken as the sole basis for calibration. The actual method adopted admits of no such chance of error creeping in, and, moreover, requires no special calculation for individual tubes.

The makers of the instruments have calculated the quantity of water in cubic centimetres that is decomposed by the passage of 25 B.T. units at the usual pressures from 100 volts upwards, and knowing this, they proceed to calibrate the tube as follows:—The first operation is to fix the tube and blank scale into the meter case, and then fill the tube with water up to the bottom of the scale, which is arranged to be well over the top of the electrodes. This water level is marked on the scale, and then a quantity of water is poured in which will be decomposed by 25 B.T. units at the voltage of the circuit on which the meter is to be used. This second level is marked on the scale, and a second quantity of water representing another 25 units is poured in, and so on until the scale is marked right up to the top. Each of these divisions is then sub-divided into 25 equal parts, so that each division on the scale may represent a B.T. unit.

In this way, any error that might occur through a slight irregularity in the bore of the tube is prevented, and, moreover, it entirely does away with the necessity of using electric current during calibration.

The above method has been tested, and, we are informed, has proved absolutely accurate in practice.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

(*Continued from page* 656.)

Salford.—The Salford Highways Committee deem it essential that a clause be inserted in the new lease of the tramways to the Manchester Carriage Company enabling the Corporation to re-lay the tramways for electrical traction during the renewed term of three years on equitable terms. The Electric Light Special Sub-committee appointed to visit certain places to inquire into systems for the supply of current for lighting and electrical traction have also made their report. They have visited London, Leeds, Brighton, and Dover, and inspected the workings of various electrical stations, and had the advantage of observing the practical working of the plants with a view to the adoption of the best system for the proposed working of the tramcars by the Corporation. The Sub-committee make the following recommendations:—"(1) That the generating plant should be erected at one station with the employment of accumulator sub-stations, the latter being a satisfactory method of utilising the plant during the hours when it would be otherwise idle. (2) That, in view of the prospective great demand for current, the engines and dynamos at the new station should be of large dimensions to secure economy in capital and working expenses, as the current generated at one station would be sufficient for both purposes. (3) That what is known as the feeder system of supply should be adopted in connection with the proposed tramlines, so as to separate the same in small sections to receive such supply. (4) That in the matter of re-arranging the proposed tramlines for the borough it would be desirable that the rails should not be less than 120 lbs. in weight per yard, and the width of the tread not less than 2 inches, and that the distance between the trolley posts to be erected should not be more than 40 yards. (5) That the method of jointing the tramlines adopted at Dover should be employed in Salford, so as to avoid the jolting in passing over the jointed portions of the lines." The sub-committee have not entered into the question of the cost which will be incurred in so extensive an undertaking, which will, of course, be done when the plans are more matured. The details of the ground plan of the new generating station proposed to be erected in Strawberry Road was explained to the officials of the stations visited, and they expressed approval of the system proposed to be adopted.

Sheffield.—Mr. A. Llewellyn Fell, the Corporation electrical engineer, and Mr. L. S. Marsh, Corporation water engineer, have, according to the *Sheffield Independent*, presented to the Tramways Committee of the City Council reports as to the possibility of obtaining water-power from the reservoirs of the Corporation for the purpose of generating electricity for tramway purposes. Mr. Llewellyn Fell says: "I have carefully gone into the question as to whether the 'compensation water' in Sheffield could be used for electric tramway purposes. As you will see from the report Mr. Marsh has drawn up, the 'compensation water,' which was generally supposed to be wasted, is really being profitably used. The separate sources of supply are so small and so far apart, that they would be useless unless they were centralised; the cost of doing this would be out of all proportion to the value of the power gained. Apparently, if the water was collected from all the available sources, only 483 H.P. could be obtained, for which no less than £116,000 would have to be paid (this sum would not include the cost of the power house site, power house buildings, turbines, dynamos, switchboards, &c.); the interest on this sum would be a fixed sum, whether the tramways were not running or were using the full available horse-power. A great point with regard to generating electricity cheaply for tramway purposes is to obtain a plant which will work economically when the load is very small; the average load on a tramway plant is about 50 to 60 per cent. of the maximum load during the 5,720 hours per annum the tramways might be run, so that during, say, 18 hours per day at least, 40 per cent. of the water would be wasted, and during six hours per day the whole of the water would be wasted. If the power was generated by steam, coal would only have to be provided for 60 per cent. of 483 H.P.—289 H.P. The coal required to produce this power would amount to 1,471 tons, at, say, 8s. per ton—£588 12s., the water evaporated would be 3,160,306 gallons, at, say, 2d. per 1,000 —£27 11s., total, £616 3s. This sum does not include the cost of power house site, buildings, engines, boilers, condensers, &c. These would cost about £5,000 more for this plant than that required for water-power. The cost of labour would be rather less if water-power was used, as no stokers would be required. As the Nether Edge and Tinsley routes will require a maximum power of about 500 H.P., the available water power would hardly be sufficient to run this line alone." Mr. Marsh's first report is a detailed and technical calculation of the amount of water-power available, namely, 483 horse-power, and the cost of centralising it, £116,600; which figures form the basis of Mr. Llewellyn Fell's report. Mr. Marsh gave it as his opinion, as water engineer, that the water supply to the town could not be utilised as a generating power. The Traction Sub-committee discussed the report at full length on March 22nd, and adjourned without coming to any definite decision. They gave instructions, however, that further reports should be submitted, showing the water-power available immediately below the embankment of the Redmires and Rivelin reservoirs, instead of centralisation. Mr. Marsh, in his second report, says that as these reservoirs vary from top water to draw-off line at different seasons of the year, he fails to see how it can be expedient or economical to use such a variable motive power. However, calculations on the suggested basis show that 109 H.P. would be available. Mr. Fell agreed with Mr. Marsh that the power obtainable from the Redmires, Rivelin, and Rivelin compensation system sources of supply would not be worth transmitting, as it is so small. Thereupon the Traction Sub-committee instructed the town clerk to write to two experts, and ask what their fee would be for visiting the reservoirs, and reporting as to the water-power available, and he was also instructed to write to a firm of hydraulic engineers and ask whether a greater horse-power could be obtained by turbines than that estimated by Mr. Marsh and Mr. Fell. The Sub-committee again met on May 3rd, 1898, and having received replies from the two experts, decided to recommend that Mr. Frederick Nell, 97, Queen Victoria Street, London, be requested to come down to Sheffield and report upon the question of utilising the water-power of the city for generating electricity, at a fee of £2 2s. per day and out-of-pocket expenses. A letter was read from the firm of hydraulic engineers, that the Committee could not depend on any greater power than that indicated in the reports; and that, in their opinion, the power would be much more cheaply obtained by the use of steam engines. The general report of the Traction Sub-committee to the Tramways Committee was as follows:—"They recommend that the city surveyor be authorised to proceed with the concrete foundations for the power station building at Kelham Island, at an estimated cost of £500, using, as far as possible, the old materials on the ground, and that he be authorised to prepare estimates for the superstructure according to the plans produced, and to advertise for tenders, and it is recommended that the Committee be authorised to affix the corporate common seal to the contract for the building as soon as a tender is accepted. The city surveyor has presented a preliminary plan, showing how the present depôt at Tinsley could be utilised as a large car shed. This plan showed that by lowering the rails under the present shed, and slightly altering the buildings and extending the shed, 30 cars could be accommodated; that by removing the stables and foreman's house on the south-west of the present shed, and erecting another similar roof, 30 more cars could be accommodated, making 60 in all, still retaining space for the repair shops and the long range of stables on the north side of the site; that by removing the last-named stables space could be provided for 20 more cars (making 80), or larger repair shops, stores, and a foreman's house could be erected; also, that by acquiring about 1,100 yards of vacant land between the south boundary of the present depôt and Weedon Street, and removing the repair shop to the north side of the depôt, the number of cars provided for might be increased to 100. The sub-committee recommend that the chairman and the city surveyor be authorised to open negotiations for the purchase of additional land. Letters from the British Thomson-Houston Company show that the sub-contractors they propose to employ under the contract are as follows:—Messrs. Milnes, for car bodies and cars; Messrs. Brown, for boilers; Messrs. Allis, for engines; Messrs. Spencer, for poles and brackets; Messrs. Wheeler, for condenser, heater, and filters; Messrs. Pearn, for pumps; Messrs. Ludwig, Lœwe & Co, for electrical apparatus; the General Electrical Company, of Schenectady, for sundries; Davy Bros., Sheffield, water tank; Seebohm & Dieckstal, Sheffield, car wheels; Peckham Truck Company, truck frames.

The Tramway Committee recommended the City Council to authorise the city surveyor—on the advice of the British Thomson-Houston Company's representative—to obtain 10,000 yards of iron tubing lined with cement, required in connection with the tramway extension to Walkley, at an estimated cost of £725; also, that the tender of Messrs. Askham Bros. & Wilson, Limited, for the necessary points and crossings in connection with the extension to Walkley from High Street, amounting to £946 13s, be accepted; further, that an order be given to Messrs. George F. Milnes & Co. for 13 double-deck car bodies at £200 each, exclusive of truck and electrical equipment; and that price and designs be obtained from the same firm for 12 single-deck cars, all of which are required for the Walkley extensions; also, that a sub-committee be appointed to settle the principle as to street improvements and tramways construction.

South Staffordshire.—The British Electric Traction Company have had their plans passed by the Brierley Hill District Council for the erection of a generating station, car shed, &c., to equip the electric tramway from Hart's Hill to Stourbridge, which is to take the place of the existing steam tramway.

The Surrey and Middlesex Light Railways Bill.—The opposition to the proposals of the London United Tramways Company to construct a light railway, with electric traction, from Kew over Richmond Hill, thence to Ham, Kingston, and Hampton Court, has, this week, so far as Richmond is concerned, taken a more tangible form. On Friday evening, a well attended meeting of the Tradesmen's Association, at which most of the leading firms were represented, passed, by 47 votes to 1, a resolution opposing the scheme. Dr. J. E. Shuttleworth, a local resident, whose views are worthy of attention, has condemned the proposal on the grounds that there is ample communication with Kingston and Hampton Court by road, rail, and river, and the Light Railways Act was never intended to apply in such a case; that the landscapes of the hill will be destroyed, the residential value of the hill and its approaches affected, and that the working of the railway will be a source of danger. The Richmond Town Council, on Monday evening, on the recommendation of the Amenities and the Parliamentary Committee, decided by an almost unanimous vote to oppose; the Surrey County Council on Tuesday also decided in a like manner; and the Richmond Vestry has passed resolutions in opposition. Meetings of residents in some of the roads affected have also condemned the scheme. A party in favour of the proposal has come forward with the suggestion to cut a new road through some of the old and congested portions of Richmond, in order to bring the line from the terminus of the present tramway along under the hill and so on to Kingston, but this idea is also condemned.

Sydney.—In the course of the presidential address at the meeting of the Electrical Association of New South Wales on March 25th, Mr. Callender, in referring to electric tramways, said that the chief development affecting engineers during the year had been the extension of the system of electric tramways in Sydney, and when the large power house now under course of construction at Ultimo was completed, it would be seen that, although Sydney had waited long and hastened slowly in this matter, the works now being erected would be such as to challenge comparison with the tramways of any city in the world, and it was a matter for congratulation that the whole of the electrical details of the work are in the hands of members of the association.

Tunbridge Wells.—The Town Council has been approached by the Electric Extension Company with a view of establishing an electric tramway in Tunbridge Wells, and the application has been delegated to a committee to report upon the matter.

Walton-on-Naze.—Messrs. Lowden Bros., of Dundee, have been engaged to supply the apparatus for working the electric cars on the pier, and also for lighting the structure. For the present the dynamos will be placed on the wharf near the Pier Hotel.

Waterford.—The Corporation of the City of Waterford have just completed terms with a Dublin syndicate for the purpose of running an electric tramway through the city. The length of track will be about two and a half miles, starting from the Waterford, Dungarvan and Lismore railway terminus, and on the one hand going as far as the Waterford and Tranmore railway station, with a branch to the top of Newtown, one of the best suburbs in the city. The capital of the proposed company will be about £22,000, and the promoter, who is a Dublin gentleman, is very sanguine of success in his undertaking. The Corporation have agreed to give the space in the streets at a nominal rent of £1 per year for the first 10 years, after which period a percentage on the profits will be paid to the municipality. It is probable that the work of constructing the line will commence within the next three months.

TELEGRAPH AND TELEPHONE NOTES.

The Blantyre and Umtali Telegraph.—The Marquis of Salisbury has congratulated the British South Africa Company and the Trans-continental Telegraph Company upon the successful telegraphic connection of the British Central Africa Protectorate and of the company's territory north of the Zambesi with the rest of the world.

The Telegraph Wire Export Trade.—The fluctuating character of the export trade of this country in telegraph wire and apparatus connected therewith is well shown by the returns just issued for the month of April last, which show a total of only £64,883, as compared with £135,583 in the preceding month, and £75,688 in April last year. The exports during the four months ending with April, are behind those of last year, having amounted to only £313,671 as compared with £321,160 in the first four months of 1897. Trade was, however, better than in 1896, during the first four months of which year, the exports only amounted in value to £211,368.

Indian Telegraph Appointments.—Three appointments in the Indian Telegraph Department are to be offered to students who join the Cooper's Hill College in 1898.

Interruptions to Australian Landlines.—The *Empire* takes strong views on this subject, as will be gathered from the following quotation, which, however, does exaggerate the general feeling in this case:—"Speaking upon the incessant interruption of the telegraph service between Port Darwin and Adelaide, Dr. Cockburn, who has control of the telegraph lines in South Australia, stated that he was fully impressed with the necessity of making an improvement in the service, and as soon as he returns to Adelaide he proposes to make arrangements for running a second line between Adelaide and Port Darwin. The wire will be carried on the same posts as the existing one, but where the telegraph crosses a watercourse the lines will be separated—one being carried up or down the stream as the case might be, about a mile or two away from the other, to lessen the risk of both lines being taken away by the floods. The line thus diverted will be carried across the watercourse on strong stout posts to prevent their being easily washed away. This 'reform' of the cable scandal is farcical. It reminds one of the philanthropic youth who offered a blind man a pair of spectacles! A few miles of wire along a stream will not relieve merchants from the exorbitant tariffs, or prevent the delays which are constantly occurring. But it will enable the South Australian authorities and the Eastern Company to protect their private interests. That is all they care about."

Parliament and the Telephone.—In the House of Commons last Friday, early in the sitting, Mr. Swift MacNeill made reference to a notice of motion down on the paper on the part of the Government, which notice was to the following effect:—"That a Select Committee be appointed to inquire and report whether the telephone service is or is calculated to become of such general benefit as to justify its being undertaken by municipal and other local authorities, regard being had to local finance; and, if so, whether such local authorities should have power to undertake such service in the districts of other local authorities outside the area of their own jurisdiction, but comprised wholly or partially in the same telephone area, and what powers, duties, and obligations ought to be conferred or imposed upon such local authorities:—That the Minutes of Evidence taken before the Select Committee on the telephone service in the session of 1895, and the report of the Commissioner and the evidence taken before him in the inquiry recently held at Glasgow be referred to the committee for consideration in so far as they relate to the subject of the present inquiry:—That the committee do consist of 17 members, and that Mr. Bartley, Mr. Griffith-Boscawen, Sir Harry Bullard, Mr. Cawley, Mr. Cohen, Mr. Culville, Sir James Fergusson, Mr. Firbank, Mr. Fry, Mr. Hanbury, Sir Reginald Hanson, Sir Henry Howorth, Sir James Joicey, Mr. John Redmond, Mr. James Stuart, Mr. Tully and Sir James Woodhouse be members of the committee."—Mr. MacNeill wished to know whether the Government intended to persist in the nomination of Sir James Fergusson, seeing that he was a director of the National Telephone Company, and as such an interested party. Sir James Fergusson, interposing, explained that he had only allowed his name to be put down in consequence of a request made to him on behalf of the Government, but on further consideration he had decided not to accept the nomination. The matter then dropped. We now learn that Mr. Donald Nicol will take Sir James's seat on the Committee, which was duly appointed on Monday last.

The Surveys of the Pacific Ocean — English and American.—In 1887 at the Imperial Colonial Conference held in London, it was unanimously resolved that a survey for a cable to connect Canada with Australia should be carried out by Her Majesty's Government. This survey is only about two-thirds completed at present. On March 2nd, 1891, an Act was passed by the American Legislature "To enable the President to cause careful soundings to be made between San Francisco, Cal, and Honolulu, in the Kingdom of the Hawaiian Islands, for the purpose of determining the practicability of the laying of a telegraphic cable between these points." This survey was thoroughly carried out and completed in May, 1892; the distance surveyed being about half of that accomplished for the English Government during the last 10 years. We extract the following from an Australian paper, dated March 25th last:—"Surveying cruise of H.M.S. *Penguin*.—H.M.S. *Penguin* yesterday returned to port after a cruise of not quite a year, during which a great deal of hard work has been done. The *Penguin* is well-known on the station as belonging to that class of ships devoted to taking soundings, charting work, and the investigation or discovery of supposed or actual dangers to navigation. Since she left here in April of last year the *Penguin* has covered many thousands of miles of ocean. Her special duty was to test the route for a cable to connect Australia with England *via* America, and she carried out the work as far as Honolulu. The testimony of her officers yesterday was that from a practicable point of view the Pacific route for a cable offers no obstacles whatever. From Sydney she went to Fiji, running a line of soundings all the way; from Fiji to Fanning Island, one of the islands under the British flag. That island was thoroughly surveyed, and found to be suitable for a cable station. To Honolulu from this island the ground was found good for cable work. After refitting at the Sandwich Islands capital, the trip across from Sydney having occupied 14 weeks, a start was made for Palmyra. This island the Americans claimed, it having been discovered by the captain of the barque *Palmyra* in 1802, but was ceded to England in 1889. The island was entirely unsuited for a cable station however, having neither a landing place nor vegetation upon it—desolate in fact—so nothing further was done there. The *Penguin* then returned to Fiji, and made a six weeks' survey of reported dangers to the north and north-west of that group, fixing positions, &c."

CONTRACTS OPEN AND CLOSED.

OPEN.

Belgium.—May 25th. The date for the receipt of tenders for the electric lighting plant at the railway station at Ghent (Gand-Sud) for the Belgian State Railway Authorities has been fixed for May 25th.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Blackburn.—May 17th. The Committee of St. George's Presbyterian Church invites tenders for the electric lighting of the Church. See our "Official Notices" last week for details.

Bury St. Edmunds.—June 13th. The Corporation invites tenders for the supply and erection of Lancashire boilers, three 60-kw. steam dynamos, transformer and booster, accumulators, street mains, and various other machinery and apparatus for the electricity undertaking. Consulting engineer, Mr. F. H. Medhurst, 13, Victoria Street, S.W. See our "Official Notices" this week.

Coventry.—June 7th. The Electric Lighting Committee invites tenders for electric mains, switchboards, arc lamps, posts and apparatus in connection therewith. For particulars of the several sections see our "Official Notices" this week. Mr. Gilbert S. Ram, city electrical engineer.

Dublin.—May 23rd. The Corporation wants tenders for the supply of high tension feeders and low tension distributors laid and jointed complete on a solid system, not including road work, but including the connecting up of existing consumers to the new mains. Also for transformers (20 to 50 kw., about 700 kw. in all) with instruments and apparatus in sub-stations erected and fitted complete. Particulars at the office of the city engineer; or from Prof. Kennedy, 17, Victoria Street, S.W. See our "Official Notices" last week for particulars.

France.—May 21st. Tenders are being invited by the French Post and Telegraph Authorities in Paris for the supply, in 10 lots, of 111 kilometres of paper-insulated electric cables. Particulars may be obtained from, and tenders to be sent to, Le Sous-Secretariat, d'Etat des Postes et des Telegraphes, 103, Rue de Grenelle, Paris.

London.—May 17th. The Bethnal Green Board of Guardians invites tenders for the supply of plant, and installing the electric light at the new infirmary, Palestine Place. Plans, &c., to be obtained from the architects, Giles, Gough & Trollope, 28, Craven Street, Charing Cross, W.C. See our "Official Notices" April 22nd for particulars.

Russia.—May 27th. Tenders are being invited by the Municipal Authorities of Odessa for the concession for the construction and working of three lines of electric tramways in the town, the total length being about 39 versts. Particulars may be obtained from La Mairie d'Odessa, Russia, to whom tenders are to be sent.

Southampton.—May 18th. The Corporation invites tenders for the purchase of a Robey slow-speed horizontal steam engine. Particulars from the electrical engineer, Mr. J. H. Lee. See our "Official Notices" this week.

Sunderland.—May 27th. The Corporation invites tenders for the supply of steam and other piping, and water softener for the electricity works. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" for particulars.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

Belfast.—The Corporation has given Messrs. Victor Coates & Co., Limited, an order for an additional Lancashire boiler for the new electricity station for next winter's load at £666 odd.

Germany.—Messrs. Felix, Singer & Co., of Berlin, have, it is reported, secured a contract for 20 4-wheel motor cars for the light electric railways at present in course of construction in the Mansfeld mining district. The cars, which are for a one-metre gauge, are to be of 40 H.P. each, the motors being on the Walker system.

Glasgow.—The following tenders have been accepted for the erection of a depôt at Springburn in connection with the tramways:—Messrs. John Porter & Sons, £2,500 for the brick and mason work; Messrs. William Shaw & Son, £529 0s. 6d. for the joiner work; Messrs. W. & D. Mailer, £145 13s. 6d. for the slater work; Messrs. P. & W. MacLellan, £336 10s. 7d. for the iron work; Mr. Matthew Sproul, £170 9s. 8d. for the plumber and gasfitting work; and Mr. Peter M'Kerracher, £38 15s. 1d. for the painter work.

Leith.—The Town Council has accepted the tender of the British Insulated Wire Company for the supply, trenching, and laying of the cables throughout the compulsory area with re-instatement of the roads and pathways, and also the supply and erection of the arc lamp-posts amounting to £7,917, in connection with the burgh lighting scheme. An endeavour was made in the Council last week to get rescinded the resolution recently passed by the Council instructing the Electric Light Committee to exercise the utmost economy. It was considered that such a motion hampered the work of the Electric Lighting Committee, and the recision seems to have been carried by six votes to five.

FORTHCOMING EVENTS.

1898.

Friday, May 13th, at 5 p.m.—Physical Society. Paper on "Galvanometers," Part II. By Prof. W. E. Ayrton and Mr. T. Mather.

Monday, May 16th, at 8 p.m.—Society of Arts. "Electric Traction," by Prof. Carus Wilson. Cantor Lecture III.—Energy diagrams—Sub-divisions of energy expenditure—Case when final speed is fixed — Possible ways of reducing the expenditure — Effect of series winding is to reduce the heat loss—Highest economy limited by the weight of the motor—How to find the best values of gear ratio and driving-wheel diameter—Example—The Baltimore and Ohio Railroad —Effect of reduction in train resistance—Use of roller bearings.

Wednesday, May 18th, at 8 p.m.—Society of Arts. "The Evolution of the Cycle," by J. K. Starley. C. V. Boys, F.R.S., will preside.

Thursday, May 19th, at 8 p.m.—Chemical Society, Burlington House. Papers to be read:—"The Action of Formaldehyde on Amines of the Naphthalene Series," by G. T. Morgan, B.Sc.; "On the Constitution of Oleic Acid and its Derivatives," Part I., by F. G. Edmed, B.Sc.

May 19th, at 12 noon.—Federated Institution of Mining Engineers' meeting to be opened at Burlington House, Piccadilly, London. Among papers to be read are:—"Roller Bearings," by Mr. W. B. Marshall; "Gas Power," by J. E. Dowson. Visit to the Central London Railway at 4 p.m.

Friday, May 20th, at 10.30 a.m.—Second day of the Federated Institution of Mining Engineers. Paper by Mr. W. T. Goolden, on "Coal Cutting by Machinery." Mr. W. Dixon's paper on the "Latest Developments and the Practical Application of Alternating Multiphase Machinery for Electric Power Transmission" will be open for discussion.

Saturday, May 21st, at 11 a.m.—Institution of Electrical Engineers. Students' visit to the works of the Electric Welding Company. Applications to join the party should be made at once to the Students' Hon. Sec.

NOTES.

Electrical Matters at Croydon.—The Corporation of Croydon, who have entered into the subject of electricity as applied to municipal purposes with much spirit, and who recently voted nearly £30,000 for the extension of their already considerable electric lighting plant, are likely to entertain, at no distant date, a suggestion to provide electric motive power for the Corporation fire engines. The suggestion emanates from Councillor T. W. Dobson, the chairman of the General Purposes Committee, which has control of the fire brigade, and it is known to have the support of, among others, Alderman Sir F. T. Eldridge, who is an influential member of the Electricity and Lighting Committee. Sir F. T. Eldridge, by the way, is chairman of a special committee appointed by the Corporation to consider the future of the Croydon tramways, the lease of which falls in in August, 1899. The present directors of the Croydon Tramways Company are preparing, in conjunction with Messrs. Kincaid, Waller & Manville, the electrical engineers, a scheme of electric traction for the trams, and are now carrying on private negotiations with the committee referred to.

Electricity in Warfare.—Our American exchanges continue, quite naturally, to devote a good deal of attention to the part being played by electrical men in the war with Spain. That American electrical men have come forward with a will is clear from the ease with which leading electrical companies and their officials have been able to get together various companies of skilled electricians for the purpose of home defence as well as for service in the navy. One contemporary discusses the effect of the war upon the electrical trade. It seems that the very urgent and heavy demands of the Government have led to the cancelling or putting aside of much of the usual business. It might be thought that these orders would make an excess of back work later on, and so keep electrical works fully occupied for a long time to come. Our contemporary thinks otherwise, and suggests that after the Government orders have been executed the electrical business will be in a bad way, as the unsettled state of affairs does not act as an incentive to new electrical enterprise.

Testing Gold Quartz by the Röntgen Rays.—An ingenious application of the Röntgen rays has recently been made, viz., to ascertain the presence of gold particles in quartz. The particles of gold in a paying gold quartz are often so finely divided as to be invisible to the naked eye. Since gold is much more opaque to the Röntgen rays than quartz, it is natural to suppose that some indication of the presence of gold in quartz would be given on the screen or the photographic plate when the quartz is traversed by the Röntgen rays. A physician in Los Angelos, California, is reported on accidentally photographing a lump of gold quartz to have found on the shadow of the outline of the quartz a number of very dark points. These points were due to the presence of particles of gold in the quartz. It is possible, therefore, to detect the presence of gold in quartz by the Röntgen rays, and it may sometimes be convenient in the laboratory, but it is not to be expected that the gold prospector will add a battery, an induction coil, and vacuum tubes to his kit.

The Manila Battle and the Telegraph Cable.—The American naval officers at Manila seem to have known what they were about in cutting the Manila-Hong Kong cable, thus interrupting telegraphic communication between Manila and the rest of the world. From what we have heard privately, they grappled and lifted the cable some miles off the town, in comparatively deep water, and buoyed both ends. They wished to stop the Spaniards from communicating from the Philippine Islands; but, as stated in the *Daily Chronicle*, they had no instruments of their own wherewith to establish communication themselves through the cable, and hence the great suspense and inconvenience which were felt in the United States pending the despatch of the *Hugh McCulloch* from Manila to Hong Kong some days later with news. We hear privately that Commodore Dewey sent ashore and endeavoured to borrow apparatus, and also to secure the services of a skilled operator; but both were refused to him by order of the Spaniards. Some interesting and important international questions are involved in the cutting of a submarine cable belonging to a neutral country in war time by a belligerent. In any case, the importance, from a practical point of view, of equipping every war vessel with the simple apparatus necessary for establishing communication through a cable, when need be, is more than evident. With the old marine galvanometer no readable signals could be obtained, but the Sullivan galvanometer, now used in our Navy, is adapted for both testing and signalling purposes, and with but a little practice, naval men should become expert in exchanging messages through cables, whenever the occasion may arise. We believe our war ships now have the means for grappling cables in shallow or moderate depths of water, as well as suitable electrical apparatus.

Wednesday's *Daily Chronicle* says that the "Eastern Extension Telegraph Company looks to the United States to compensate it for cutting the cable at Manila. But Admiral Dewey did not cut it till the Spanish authorities refused to allow the transmission of American despatches. Therefore the real interruption of the earning capacity of the cable was due to Spanish action, and Lord Tweeddale had better apply for compensation to Madrid."

The Parliamentary Committee.—A further meeting of the Joint Committee on the question of Electrical Supply and Electrical Generating Stations was held on Monday, at which the heads of their report were discussed. A section of the Committee are, according to the *Standard*, in favour of abolishing the present system, by which the power of purchase comes in at the end of 42 years, and of modifying it so that purchase may take place at a shorter period—perhaps 25 years—on the basis of the net profits of that time. This would lessen the burden on the companies by rendering it unnecessary that they should devote so large a part of their income to a sinking fund. Another point raised was the advisability of a sliding scale in regard to the profits of electric companies, like that provided for by the Gas Acts. It is probable that a recommendation in its favour will be adopted. A question has also arisen as to whether, within a fixed radius, a *locus standi* should not be given to adjoining owners to oppose the establishment of generating stations, and also as to whether compensation ought to be paid to adjoining owners in consideration of such nuisances as those which may arise from vibration, &c.

Glasgow Technical College.—The following candidates have been passed for the diploma in electrical engineering, viz.:—John S. Nicholson (Aberdeen), Geo. H. Van Corbach (Shanghai), Wm. N. Brand (Glasgow), J. Bruce Kingsmill (Ireland), Fred. Ussing (Copenhagen). Mr. Nicholson has been nominated for the Sir John Pender Gold Medal, and Mr. David Robertson, jun. (Uddingston), the previous John Pender medallist, for the Pender Scholarship.

The Royal Society.—Among the papers read before this society yesterday afternoon was one by Prof. Gotch, F.R.S., and Mr. G. J. Burch on "The Electrical Response of Nerve to a Single Stimulus Investigated with the Capillary Electrometer. Preliminary Communication," and one by Mr. S. R. Roget on "Effects of Prolonged Heating on the Magnetic Properties of Iron."

The Telephone Question.—There has been published in pursuance of the order of the House of Commons, copy of the agreements entered into on March 25th and 26th, 1896, between the Postmaster-General and the National Telephone Company for the transfer of the trunk lines. The features of greatest interest at the moment will probably be the exchange or "terminal" charges provided for under clause 8, where a telephonic message is transmitted over the trunk wires between an exchange of the National Company and an exchange of the Post Office or some licensee other than the National Company; and clause 18, which says that the agreement shall not prejudice or affect the right of the Postmaster-General to establish telephonic communication himself or license others to do so. The abstracts show that the transfer of lines amounted to nearly 30,000 miles of wire, and when to these are added the lines built by the Post Office themselves, it will be seen how important a branch of the Telegraph Department the trunk telephone lines have become.

Train Lighting.—In a communication to the *Railway World*, Mr. W. Langdon says that few will deny that, to the experiments in the electric lighting of trains carried out by the Midland Railway Company, the industry is much indebted. Those experiments dealt with the subject in such a comprehensive manner, as proved the applicability of electric lighting to the various demands of railway service, and although the circumstances which at that time attended the efforts were such that it was felt advisable to abandon the experiment for the time, the success attending those trials was quite as efficient from a lighting point of view, as that arising from the Stone system. The reason for their withdrawal was not so much one of cost as one of convenience. Mr. Langdon adds: "The rolling stock of a railway is no more exempt from wear and tear than other mechanical appliances, and from time to time vehicles must necessarily come in for repairs. Out of this arises one of two things, either the interposition of unfitted stock, and consequent severance of electrical connection, or the remarshalling of the train at any point at which such unfitted stock has to be interposed." He asks what advantage is possessed by Stone's system over that of the Midland or other systems? "It is based upon the same lines with the exception that whereas in other systems the varying speed is compensated by electrical adjustment, in Messrs. Stone's system it is met by the slip of the belt. There is no doubt that a self-contained system has attractive features from a traffic point of view—it disposes of the remarshalling question, and it is extremely convenient for trial purposes; but conceive a large system, such as the Midland, with all its passenger stock—some 3,800 coaches and vans—fitted with dynamos all arranged below the bed-frame of each vehicle, and set against this the number of electric generators, arranged above board, which would be required if the light were operated on the Midland system—*i.e.*, from one vehicle in each train—and say which ought to prove the most convenient and economical to maintain, 380 generators above board or 3,800 below board." The many trials which are being made by railway companies of Stone's system show how anxious they are to adopt electricity for carriage lighting if its cost is reasonable. That electricity is *the* illuminant for the purpose Mr. Langdon has not the least doubt, but whether it is to be done by fitting each vehicle independently rather than in groups, he considers is open to question.

Wireless Telegraphy.—A demonstration of the Marconi system took place on Thursday last week at the offices of the Wireless Telegraph and Signal Company, Limited, 28, Mark Lane, E.C. Amongst those present were the President of the Board of Trade, the Right Hon. Charles Ritchie, M.P.; Sir Courtenay Boyle, Lord John Hay, Admiral of the Fleet; Lord Kelvin, Sir William des Voeux, Lord Charles Beresford, Lord Stanley, Mr. C. Farquhar, Mr. E. Beaumont, Q.C., Admiral Compton Domvile, Mr. R. G. Hayes, Commander Evan Thomas, Mr. Charles Wilson, M.P., Colonel FitzGeorge, A.D.C., and Captain the Hon. C. Colville. Mr. Marconi was at the transmitting end, and Lord Charles Beresford read the messages printed on Morse tape in another room in the building, all of which were easily decipherable.

The Spiral Globe, Limited.—Since the brief notice in our issue of May 6th of "The Spiral Globe, Limited," we have given careful consideration to the claims advanced in the prospectus of the improvement in the illuminating power of an ordinary incandescent lamp by winding a glass rod spirally round it. The first point we considered was the report of the Electrical Standardising Testing and Training Institution, signed by Mr. Hugh E. Harrison. The net result of the experiments on which the report is based appears to be that if a set of annular glass pieces of circular section are disposed about an irregular source of light, the effect of reflection and refraction at the surfaces of the glass will be to intensify the radiation in both directions along the axis of the annuli, and in consequence, though this is not mentioned here, to reduce the equatorial radiation. Figures are given of four dispositions of such an arrangement about an ordinary incandescent lamp, involving seven experiments. From general considerations of the paths of the rays of light this result seems reasonable, though the disposition of the glass surfaces and the sources of light are too complicated to admit readily of a geometrical investigation. Now of the seven experiments, five, giving three comparisons, deal with the spiral globe in the form in which it is proposed to apply it, and all three show considerable increase of intensity along the axis of the lamp, no reference being made to the necessary consequent equatorial diminution of intensity at right angles to the axis. The other comparison deals with the spiral arranged so as to produce an increased equatorial intensity in one direction only—an arrangement which does not appear to be contemplated in practice, and has no bearing on the matter in question. It is not clear why this is introduced, but it might give an impression to an inexpert reader that the spiral globe increases the equatorial intensity as well as the axial. Consider the general action of lenticular arrangements. They are never introduced to increase the all-round, or average radiation, and must in every case reduce it by the opacity of the glasses and the dirt collected on their surfaces. Their sole purpose is to direct rays of light radiated in a useless direction along a useful one, at the expense of some loss. Now, though this prospectus claims an improved distribution, viz., an increased vertical and a reduced horizontal one, it gives no reason for claiming this to be an improvement, nor can anyone say, for an ordinary incandescent lamp, that any particular direction of radiation will be necessarily more useful to its future purchaser than another. So far as one can say anything, it is that it is not generally convenient to increase the upward radiation at the expense of the horizontal or oblique. To us the modification made does not commend itself. The prospectus further claims that the spiral globe "more than doubles the effective light emitted," "and insures a corresponding economy in the consumption of electrical current." The spiral globe does nothing of the kind. Its effects appear to be three. It will increase the illumination above and below the lamp, where it may or may not be wanted, and diminish it horizontally, with, on the whole, a loss. It will no doubt be a pleasanter and less intense light for rooms, but this advantage is got in many other ways. Its surface, inevitably more or less dirty, will reduce the general efficiency, and when the lamp is placed in an unfavourable position, so that dust accumulates, will do so very largely. It would be very difficult to clean. As far as we see every one of the seven advantages claimed for the globe in the prospectus is ridiculous, looked at from an investor's point of view. If this document is to be construed in the way most convenient to the promoters that its ambiguously qualified claims admit, we can only say it is not a very ingenious specimen of its class. If it is to be construed by the meaning it would convey to an intelligent inexpert reader, it is, to say the least, misleading.

Electric Traction Lectures.—Prof. Schwartz and Dr. D. K. Morris will commence their series of six lectures on "Electric Traction" at the South-Western Polytechnic, Chelsea, on Tuesday next, at 7.30 p.m. The lectures will deal respectively with:—1. Power stations; 2. Overhead conductors; 3. Conduit and surface contact systems—The permanent way; 4. Motors and rolling stock; 5. Accumulator cars; 6. Working expenses—Maintenance and depreciation.

Technical Education in Ireland.—The Dublin Corporation last week passed a lengthy resolution requesting the Government to appoint immediately a committee of eminent educational and scientific authorities, together with representatives of the manufacturing, industrial, and commercial interests in Ireland, to inquire into the question of the need of Ireland in regard to primary, secondary, and higher technical education. The Government is to be asked for a £100,000 grant for the purposes of the Royal College of Science for Ireland. The Lord Mayor of Dublin in a speech upon the subject said: "As regards higher technical education it was certainly little less than a scandal and disgrace to the Government that not a single chair of mechanical or electrical engineering, to say nothing of architecture, existed in the whole of Ireland."

Appointments.—The Glasgow Electricity Committee has passed a recommendation to the Council to appoint Mr. John Christie, of Londonderry, as station engineer, and Mr. J. C. A. Ward, of St. Pancras mains department, as superintendent of mains. The appointments are, of course, subject to confirmation by Council on the 19th inst., but the committee was unanimous in both cases.

Lecture.—Before the Ipswich Scientific Society on 4th inst. Mr. S. A. Norcutt lectured on "Phenomena of Electrical Discharge."

Self-Charging Motor Car.—Mr. L. Epstein has recently patented a new electric motor car, in which he claims to have overcome the difficulties presented by batteries becoming exhausted at a distance from a charging station. It is admitted that it is one of the great drawbacks of electric motor cars that the batteries require periodical re-charging, this necessitating the existence of charging stations, and considerable rough usage of the accumulators in taking them out for charging and putting back in position again. These drawbacks are said to be avoided by the Epstein motor car, which is self-charging, inasmuch as it is equipped with the necessary apparatus for automatically charging the cells whenever and wherever required, with very little difficulty. The car is equipped with Epstein cells of a special type, and an oil engine, and the motor can be reversed for use as a dynamo for the purpose of charging the cells. The extra equipment is stated to be responsible for an additional weight of only 3 per cent., compared with the ordinary electric motor car. The weight of a self-charging car, complete with all equipment and four passengers, comes out at something under 30 cwt. The accumulators weigh 7 cwt., and are considered sufficient for a 60-mile run on ordinary roads. We understand that Mr. Epstein now has one of the cars in course of construction.

Pacific Cable.—A daily paper says that the British ship *Penguin*, which had to take soundings and to investigate the bottom of the Pacific, with the view to the laying of a cable, arrived at Sydney on March 25th. According to the *Frankfurter Zeitung*, her officers declared that the soundings showed no obstacles.

Appointment Vacant.—The Stockport Gas and Electric Light Committee want a clerk of works at £3 per week. See our "Official Notices" this week for particulars.

The Electrical Press.—The number of journals partly or wholly devoted to electrical subjects amount in the total to 66. Of these 18 are published in France, 14 in the United States, 12 in Germany, 6 in England, 3 in Switzerland, 2 each in Austria, Belgium, Holland, Italy and Spain, 1 each in Canada, Japan, and Russia.

The Pender Memorial.—One of the two marble busts of the late Sir John Pender, G.C.M.G., executed by Mr. E. Onslow Ford, has now been received by the authorities of University College, London. The bust has been placed in the library. The likeness is stated to be a pleasing and striking one. The second bust is at present on view at the New Gallery, and will afterwards be sent to Manchester for exhibition.

Calcutta University.—The Senate of this University is considering the subject of degrees in science. The committee appointed to report on the subject considers, says an Indian journal, the institution of such degrees desirable for the encouragement of original research by the graduates of the University.

Dust Destructors in India.—The Vizagapatam Municipal Council has resolved to construct a Roberts's patent incinerator. An Indian exchange says that this will minimise the difficulty now felt by the Council in the proper disposal of rubbish, the present sites in town having been condemned by that officer.

King's College Old Boys.—We hear that Mr. W. H. Preece is to preside at the King's College School Old Boys' annual dinner at the Criterion Restaurant on Friday next, May 20th.

NEW COMPANIES REGISTERED.

Chilian Electric Tramway and Light Company, Limited (57,203).—Registered May 3rd, with capital £1,050,000 in £1 shares (550,000 preference), to adopt an agreement with the Allgemeine Electricitäts Gesellschaft, of Berlin, to acquire, equip, maintain and work by horse, electrical, steam, or other power, any tramways or railways in Chili or elsewhere in America, and to carry on the business of electricians, electrical engineers, suppliers of electricity, &c. The subscribers (with one share each) are:—E. F. Rouse, 1, Avenue Gardens, Mill Hill Park, W., gentleman; W. G. Turnbull, 95, Wood Lane, Shepherd's Bush, W., clerk; G. F. Barnett, 12, Weston Park, Crouch End, N., clerk; J. Jewell, 13, Richmond Crescent, Barnsbury, clerk; C. Field, 27, St. Margaret's Road, Brockley, S.E., clerk; H. A. Milner, 84, Effingham Road, Hornsey, N., clerk; W. MacGillivray, 368, Green Lanes, N., book-keeper. The number of directors is not to be less than six nor more than 12; the subscribers are to appoint the first; qualification, £500; remuneration as the company may decide. Registered by Ingle, Holmes & Son, 20, Threadneedle Street, E.C.

Silverton Ironworks, Limited (57,218).—Registered May 4th, with capital £50,000 in £1 shares (10,000 preference), to adopt an agreement with F. O'C. Prince for the acquisition of an invention for improvements in furnace bars, and to carry on the business of mechanical engineers, machinists, wood workers, builders, timber merchants, electrical engineers, chemical manufacturers, &c. The subscribers (with one share each) are:—T. Willson, 2, Christchurch Road, Hampstead; architect; H. Howe, 6, Epirus Road, Walham Green, S.W., gentleman; A. R. Stanes, The Limes, Surbiton, merchant; L. F. Clow, 8, Old Jewry, E.C., land agent; F. O'C. Prince, 37, Cursitor Street, E.C., engineer; E. J. V. Davies, 1, Harringay Villas, N., engineer; A. E. Bloxham, 17, Boveney Road, Honor Oak Park, S.E., agent. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, 400 ordinary or 200 preference shares; remuneration, £100 each per annum (£150 for the chairman), and a percentage of the profits. Registered by N. L. Pocock, 16, Finsbury Circus, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Cambridge Electric Supply Company, Limited (36,457).—This company's annual return was filed on March 2nd; 9,413 shares have been taken up out of a capital of £100,000 in £10 shares; £8 per share has been called on 4,970, and £1 per share on the others, and £44,203 has been paid.

Telegraph Construction and Maintenance Company, Limited (1,147 C).—This company's annual return was filed on March 23rd, when the whole capital of £448,200 in £12 shares was taken up and paid for in full.

W. T. Henley's Telegraph Works Company, Limited (13,795).—This company's return was filed on March 18th. The capital is £180,000 in £10 shares (3,000 preference), 12,500 ordinary and 3,000 preference have been taken up, and £155,000 has been paid.

British Insulated Wire Company, Limited (52,285).—This company's annual return was filed on April 15th. The capital is £400,000 in £5 shares (40,000 preference). 20,000 preference and 40,000 ordinary shares have been taken up, and 5,530 preference and 29,935 ordinary are considered as paid. £2 15s. per share has been called on the others, and £67,471 5s. has been paid, leaving £55,203 15s. in arrears.

CITY NOTES.

The West India and Panama Telegraph Company, Limited.

The directors' report for the half-year ended December 31st, 1897, to be submitted to the shareholders on May 18th reads as follows:—The directors submit the accounts for the six months ended December 31st, 1897. The amount to credit of revenue is £32,228 11s. 8d. against £34,053 13s. 6d. for the corresponding half-year of 1896, and the expenses have been £19,772 15s. against £21,398 15s. 4d., leaving a balance of £12,455 16s. 8d., which, with £1,243 6s. 8d. brought from last account, and £1,000 transferred from reserve account, makes a total of £14,699 3s. 4d., with which it is proposed to deal as follows:—

	£	s.	d.
First preference shares—			
Dividend, six months to December 31st, 6s. per share	10,368	18	0
Second preference shares—			
Dividend, six months to December 31st, 6s. per share	1,400	14	0
Ordinary shares—			
6d. per share (free of income-tax)	2,208	0	6
Balance to current half-year's account	721	10	10
	£14,699	3	4

The traffic receipts for the six months show a decrease of £2,187 19s. 8d., as compared with the corresponding period, attributable to the causes mentioned in the last report, and to the depressed condition of West Indian trade. The expenses of repairing cables during the half-year are £1,386 15s. 3d. less than those for the corresponding period. During the half-year the company's two repairing steamers, *Grappler* and *Duchess of Marlborough*, have been surveyed and repaired in accordance with Lloyd's requirements. The new cable between Bermuda and Jamaica, alluded to at the last general meeting, was opened for traffic on January 31st. The contract between Her Majesty's Government and the new company provides for a subsidy of £8,000 per annum, and for a maximum tariff of 3s. per word between London and Jamaica, as against 5s. 10d. per word charged by the route as prescribed by the Legislative Acts of the Colonies, *viâ* Havana. The directors, however, decided to make corresponding reductions of rates to and from the West Indies on January 1st. With the view of aiding the plans of the Government in furtherance of West Indian trade, reductions of inter-colonial rates were also made on April 1st. Since the last general meeting the directors, with the object of maintaining and strengthening the duplicate system, have made arrangements to connect Grenada, St. Lucia and St. Croix, by a new line of cable in substitution for the old Chord line, which has proved to be beyond repair, and to duplicate the Trinidad-Grenada section. A contract has also been entered into for the manufacture and delivery in the West Indies of 160 knots of cable for stock. Owing to the financial crisis through which the Leeward Islands are now passing, Antigua and St. Kitts have reduced their subsidies from £800 to £600 each for the current year. Notice has also been received from the Government of Jamaica that the subsidy of £2,000 per annum, hitherto paid to this company, has ceased from March 31st. In accordance with the articles of association, Henry Holmes, Esq., retires at this meeting, and offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, and offer themselves for re-election.

The Great Northern Telegraph Company of Copenhagen.

The general meeting of this company was held at Copenhagen on April 30th, 1898, Mr. F. Zahle presiding.

The chairman and managing director, Commodore E. Suenson, D.R.N., in rendering an account of the working of the company during the year 1897, stated that the state of the cables in Europe had not been satisfactory during 1897, especially towards the end of the year. No fewer than 11 of the cables had been interrupted, the total number of interruptions being 32. These had nearly all been due to injury caused by the fishing vessels, especially by the steam trawlers, which are spreading more and more, not only over the North Sea, but also in the Skager Rack and Kattegat. On the other hand, the cables in the Far East had been comparatively free from injury, thanks to the extensive strengthenings and renewals which had been carried out during the last years, particularly on the Hong Kong-Amoy-Shanghai line. There had been only seven interruptions, affecting five cables. Unfortunately the Wladiwostock route had, as usual, been the weak link in the system. An altogether exceptional inundation of the Amur River had to a great extent destroyed the work of reconstruction carried on by the Russian Administration, and the work had to be done afresh. This reconstruction would, he hoped, put an end to the repeated interruptions of this route, while, as the construction of the railway in Siberia advances, the maintenance of the line would be facilitated. Their telegraph system in Europe would be improved in course of the present year, thanks to a measure contemplated by the Swedish Administration, viz., the building of bronze wires across Sweden. This would be of great advantage to the considerable traffic crossing that country between Gothenburg and Grislehamn. Similarly the Danish Administration had improved the lines across Denmark by the introduction of oil insulators; while the Russian Administration had built a new direct line between Moscow and Libau in order to accelerate the transmission of the telegraph traffic with the central and southern parts of Russia. The continued commercial and industrial development of China and Japan, and, during the last months of the year, the political events in the Far East had tended to increase the traffic. The friendly relations established with the Chinese Administration in 1896, by the convention concerning the traffic exchanged between Europe and China, which was mentioned in the last report, had been further consolidated by a similar convention concerning the limitrophic traffic between the Russian and Chinese Empires. In Japan they had had protracted negotiations with the Telegraph Administration, complicated by the introduction of the gold standard into that country. These negotiations eventually led to a tariff arrangement, which had also contributed to develop the traffic. Speaking of the projected Iceland cable, the Chairman said as the cable would render important service to Great Britain, France, and others, which every year send a number of fishing vessels to the coast of Iceland with crews numbering thousands of men, the company had provisionally approached Great Britain, France, and Russia in the hope of obtaining in return for the free transmission of their meteorological telegrams a fixed yearly remuneration which might contribute towards making up the deficiency in the receipts. The financial result of the year has been very satisfactory. The decrease in the receipts was only apparent, and was due merely to a change in the method of making up the accounts and balance-sheet. The interest on investments belonging to the reserve and renewal fund had been added direct to this fund, instead of being, as before, first entered in the working account. The latter method, which was less correct, was followed for so long a time, only with the object of enabling the employment of a larger amount for the amortisation of the debentures, but as the whole debt of the company would probably be extinguished in the course of another 12 months, the more correct method has been introduced this year. This alteration has not affected the extra dividend, which has been fixed as last year at 10s., making a total dividend of 10 per cent., or 20s., whilst the reserve and renewal fund has been increased by an amount slightly smaller than ordinarily.

The accounts were then adopted, and the retiring directors and auditors were re-elected.

The Eastern Extension, Australasian and China Telegraph Company.

The forty-ninth half-yearly meeting of the above company was held on Wednesday last at Winchester House, Old Broad Street, the Marquis of Tweeddale presiding.

The Chairman, in moving the adoption of the report, said: Gentlemen, the gross revenue for the half-year under review has amounted to £275,142, or a decrease of £50,263. Of this, £20,000 was caused by the falling off of the Australian traffic, which we have always pointed out to you is more or less of a temporary character, the remainder being due to reductions of tariff. When these reductions were made, it was estimated that there would be a loss of over £55,000, and it is most gratifying, I think, to find that the falling off in revenue from this cause has not been nearly so great as was anticipated. The working and other expenses have amounted to £102,844, showing a decrease of £3,426, which is due to the cost of maintenance of cables and expenses in connection with negotiations having been less in the past half-year than in the corresponding half-year of 1896. The usual interim dividends have been distributed during the past year, making, with a final dividend proposed to be paid to-morrow, a total payment of 5 per cent. for 1896; a bonus of 4s. per share, or 2 per cent. will also be paid, making a total distribution for the year of 7 per cent. The revenue balance, amounting to £57,444 13s. 10d., has been carried to the general reserve fund, which now stands at £803,667, after having been debited with £79,619 for the cost of the cable renewals, &c., carried out during the half-year under review. These renewals have been made in the Malacca Straits and China seas, and during the current year it is proposed to carry out several other much-needed renewals in various sections of the company's system. A further drawing by lot of the company's Australasian Government subsidy debentures (451 in number) took place on the 4th ult. for payment at par on July 1st next, when the debenture debt, which originally amounted to £640,000, will be reduced to £80,600. When I last had the pleasure of addressing you, I referred to the subsidy arrangement entered into with the Spanish Government for extending the company's system from Manila to the islands of Panay, Negros, and Cebu. During the half-year under review, this contract was completed to the satisfaction of the Spanish Government, and the cables opened for traffic. Unfortunately, however, through a further outbreak of the rebellion in the Philippines, one of the new stations in Cebu (Tuburan) has had to be abandoned, and is reported to have since been entirely destroyed, and until the rising is quelled, or sufficient troops can be spared to garrison the place, the working of the station cannot be resumed. Our Bolinao station, where the Hong Kong cable was originally landed, was also in the greatest danger a few months ago, owing to large numbers of the rebels having assembled in the neighbourhood, and demanded the surrender of the Spanish soldiers (11 in number) who had been sent to Bolinao to protect it. The Government landlines between Bolinao and Manila had been cut by the rebels, so that it was quite impossible for the station to communicate with the authorities at Manila by telegraph. For four days the station was entirely surrounded by the insurgents, who constantly threatened to attack it, and but for the timely arrival of a Spanish gunboat the station must have surrendered, with the result that the soldiers would doubtless have shared the sad fate of the other small garrisons in the district, who, after receiving promises of safety, were cruelly murdered. During this trying time the company's staff at Bolinao displayed the greatest courage and loyalty, and we understand that the Governor-General has recommended the Spanish Government to recognise their valuable services by conferring upon the superintendent and other principal members of the staff suitable decorations. The insecurity of the landline between Bolinao and Manila had long been recognised by the Government and mercantile community of Manila, and many proposals had been made from time to time for improving it, but without any practical result. The troubles, however, to which I have just referred were the means of bringing the negotiations between the company and the Spanish Government to a head, and a contract was entered into on March 30th for cutting the Hong Kong cable off Bolinao and extending it direct to Manila in return for certain concessionary privileges. The work was carried out within a fortnight of the contract being signed, and the Bolinao station and staff removed to Manila. They had not, however, been working from Manila many weeks before hostilities broke out between the United States and Spain, and on Monday, the 2nd inst., at 8 p.m., the cable was suddenly interrupted close to Manila, we believe by the order of the admiral of the American fleet. Should this prove to be the case, we shall naturally look, and with the utmost confidence, to the Government of the United States to compensate us for the damage caused to our property. Communication by cable between Manila and Hong-Kong will not be restored, I am afraid, until we are in a position to repair the cable, and until peace has been restored between the two belligerents, which, I am sure, we all hope will soon be the case. You will have seen from the newspapers that the proposal which the Eastern, Eastern Extension, and South African Companies submitted to Her Majesty's Government for establishing an all-British cable between this country and Australia *viâ* the Cape of Good Hope, has of late received a good deal of attention both in the colonies and on this side, but up to the present time the departmental committee has not made its report, and consequently no definite result has been arrived at. You will remember that at the last meeting a suggestion was made to the board that the services of the staff should be specially recognised in connection with the celebration of the Queen's Jubilee. This suggestion, after receiving the board's careful consideration, was adopted, by the granting of bonuses to the whole of the company's employés, and the expenditure incurred will appear in the accounts for the current half-year.

Mr. F. A. Bevan seconded the motion, and the report was adopted.

The retiring directors and the auditors having been re-elected, the proceedings terminated with a vote of thanks to the chairman and directors and to the staff.

American Bell Telephone Company.

The American Bell Telephone Company's report for the year 1897, gives the estimated number of exchange connections in the United States as 998 millions; the increase in the number of subscribers reported by the licensee companies was unprecedented in the history of the business, the gain in the last two years having equalled the aggregate gain of the previous six years. The number of exchange stations is 384,230, which equals, within a few thousand, the aggregate number of exchange stations in all of Continental Europe. The German Empire is reported to have 122,362 exchange stations (1896), and Great Britain comes next with 85,316. Conversation is now had by subscribers in the United States over distances of 1,800 miles.

West Coast of America Telegraph Company.

Mr. J. Denison Pender presided at a meeting of this company held at the offices of the company, Winchester House, on Tuesday last.

The Chairman referred to the death of Lord Sackville Cecil, one of the directors, whose seat at the board had been filled by Sir Albert J. Leppoc Cappel. The gross receipts for the year amounted to £25,773, being an increase of £2,268 of the previous year under the old company. The expenditure had been £19,476, or a reduction of £2,812, which was attributable to their having only one section of the cables interrupted during the year. The repairing steamer *Retriever* was only away from port five days during the 12 months, thus effecting a great saving in working expenses and maintenance of cable. Taking into consideration the depressed state of trade, the result of the first year's working of the new company could not be considered unsatisfactory. At the same time, the expenses had been abnormally small. The scheme of reconstruction took over the business, goodwill, property and assets, with liabilities of the old company, from December 31st, 1896. Of the share capital, 30,000 shares of £2 10s. each had been allotted to shareholders of the old company, and 15,000 of a similar amount had been allotted to the Brazilian Submarine Company. 8 per cent. debentures had been exchanged for 4 per cent., and £20,000 in 4 per cent. income bonds had been issued. The chairman referred to correspondence which had appeared in the financial press, and described the remarks of the writers as absolutely inaccurate.

Elmore's German and Austro-Hungarian Metal Company, Limited.

Mr. John MacFarlan (chairman) presided over the seventh annual meeting of the above company, held on Wednesday at Winchester House, and in moving the adoption of the report said the reduction of capital had been carried out and the amount standing as cost of patents was reduced from £139,940 to the more reasonable figure of £84,252. At the same time the period during which the preference shares had nine-tenths of the profits had been extended by two years in consideration of the additional sum of £10,000 put in the business. With regard to the Metall Company the result of the year's trade was disappointing as they fully expected the profit would have been sufficient to have paid a dividend. The explanation of the cause of their failure was a simple one. They got the Government contract and were told the requirements would be 100 tons per annum. They quoted a low price in view of the benefit they would derive by getting the contract. The result was that they received orders for more than three times the amount they expected at the lowest price. As soon as they got the Government order they were inundated on all sides with orders, but in consequence of the Government work they could not accept them. The contract with the navy was cancelled by them, and they had secured nearly the whole of the new one, only very small tubes going elsewhere, at prices very much higher than those of the old contract. The fact of their obtaining the new contract proved the esteem in which their tubes were held by the Government. They were informed by the Hamburg-South American Steamship Company that they had specified in their contract that only tubes of their make should be used. The most important fact of all was that they were now in a position to give orders for a very considerable extension of their plant, and they were now completing the erection of new plant which would enable them to about double the sales of last year. They had erected a very large draw bench shed, and filled it with draw benches, and they had built a very large double annealing furnace, which with the draw benches was sufficient to deal with the output. They were also deriving considerable benefit from the new arrangements with regard to the purchase of copper, and were now in the happy position of getting all copper free at Schladem at from 30s. to £2 a ton less than the value of Chili bar, and at the same time they paid nothing for the gold and silver it contained. They obtained 391·4 ounces of gold, which was sold for £1,692 3s. 6d., and 11,364·22 ounces of silver, which sold for £1,481 4s. 2d. That was a very important point, as that bye-product increased with increased output. On December 31st they had locked up in copper and book debts no less than £24,512 6s. That sum was considerably greater now, and it was impossible for them to carry out the extension without copper to fill the tanks. The debenture stock fell due for repayment on July 1st, and they proposed to make an issue of £60,000 to replace that. With the increase of business, they felt they were justified in reducing the interest from 8 per cent. to 6 per cent.

Mr. Heal seconded the adoption of the report, and it was agreed to.

Mr. Rawson stated that the shareholders would be glad to hear that the French Elmore Company would probably pay a dividend of between 10 and 20 per cent.

The Western and Brazilian Telegraph Company Limited.—The directors have decided, after placing £5,000 to the reserve fund, to recommend the payment of 6s. 9d. per share, making, with the interim dividend paid in November last, a total distribution of 3¼ per cent. for the year 1897. This will give 6s. 9d. to the ordinary, 6s. to the preferred ordinary, and 9d. to the deferred ordinary shareholders.

Stock Exchange Settlements.—Application has been made to the Stock Exchange Committee to allow the following securities to be quoted in the Official List:—Oxford Electric Company, Limited—10,000 shares of £5 each fully paid, and £35,000 4 per cent. debenture stock.

Forthcoming Prospectus.—The various daily and evening papers announce that the Great Northern and City Electric Railway prospectus will shortly be before the public.

New General Traction Company.—The meeting of this company, convened to be held yesterday, was not held, but was postponed until the 17th inst.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending May 6th, 1898, were £2,478 2s. 4d.; corresponding period 1897, £2,271 9s. 5d.; increase, £206 12s. 11d.

The City and South London Railway Company.—The receipts for the week ending May 8th, 1898, were £964; week ending May 9th, 1897, £957; increase, £7; total receipts for half-year, 1898, £19,721; corresponding period, 1897, £19,503; increase, £218.

The Dover Corporation Electric Tramways.—The receipts for the week ending May 7th, 1898, £130 11s. 8d.; total receipts to May 7th, 1898, £2,082 2s. 8d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, May 6th, 1898, were £461 0s. 2d.; corresponding week last year, £511 7s. 2d.; decrease, £50 7s.; passengers carried, 76,828; corresponding week last year, 78,961; aggregate to date, £7,[illegible] 17s. 3d.; aggregate to date last year, £8,166 11s.; decrease to date, £336 13s. 9d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending May 8th, 1898, amounted to £1,504; corresponding week last year, £1,316; increase, £188.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending May 6th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,178.

REVIEWS.

Alternate Currents in Practice. By FRANCIS J. MOFFETT, B.A. London: Whittaker & Co., 1898.

This work is a translation of a treatise of MM. Loppé and Bouquet, and has been undertaken by the translator with the idea of supplying English readers with a practical treatise covering the whole range of alternating currents of electricity.

It is rather a difficult matter to cover the whole range of a subject like alternating currents in a book containing only 372 pages, and we cannot expect to find in so small a space anything like complete treatment.

The book is divided into seven chapters, dealing with (I.) Alternators; (II.) Motors; (III.) Transformers and Condensers; (IV.) Transformation of Current; (V.) Distribution mains; (VI.) Current Distribution, and (VII.) Industrial Measurement of Alternating Currents.

The first three chapters, which comprise 247 pages, or about two-thirds of the whole book, are a mixture of description and theory such as is already within the reach of English readers, so that the useful addition to our literature is limited to the remaining one-third, which deals with the transformation and distribution of alternating currents. This portion should materially help electrical engineers, and form a useful reference for reasons and data concerning the various distributing systems, and it is really this part which is most suggestive of the practical engineer. It contains a good account of the methods employed in transforming from one alternating current system to another, and deals generally with the problems of transmission and distribution of electrical energy. The descriptive portions of these chapters is decidedly good, and the theoretical treatment is of a simple nature. The descriptive parts of the first three chapters are all that can be desired, the language being clear and the illustrations good, but the theoretical parts are often long and tiresome.

It seems to be a mistake to attempt to make a treatise on such a subject cover both practice and theory. There is plenty of room for two distinct treatises, one entirely practical in which difficult theoretical results may be stated but not proved, and the other devoted to establishing results whether they are known to have application to practice or not. If we were so supplied we should often be saved the tedium of hunting for practical data in book after book in the hope of finding what we want, perhaps hidden in a mass of—at the time—uninteresting figures and symbols.

The work before us is avowedly a translation, and it is, perhaps, a little out of place to review it as an entirely new production. As a translation, the book can only meet with a favourable criticism. The language is throughout precise and clear, and the diagrams and illustrations well defined and clearly explained. It would have been better if the publishers could have seen their way to produce the work at a lower cost. The price, 15s., does not compare well with other equally good publications of theirs.

An Eight Hours' Day. By W. J. SHAXBY. London: The Liberty Review Publishing Company, Limited.

This little book deals with the eight hours' question, and is generally inimical to it, and prophesies ruin if it is adopted. Our own opinion on the matter is that eight hours honestly and heartily worked, are sufficient for a day's work, and we see no advantage in meeting foreign competition by long hours of labour. Foreign competition will not gain the day on the question of hours. It rests with the workers of the country to maintain our trade by something very different from what trades unionism has fostered of late years. We fear both the van and the rear of English trade is badly officered. Improvement must come at both ends.

The intermediates who often find the brains, and have not the authority, are usually the best men. We agree with the author in condemning legislative interference, but we are by no means entirely with him on the hours question. Any length of day is useless where the spirit to utilise it is not there. We never looked on the recent strike as turning upon the hours question. It rather turned on other considerations, which were concealed behind the so-called popular eight hours. As a fact, there is yet no real public feeling for an eight hours' day, and to force it forward is an error by whomsoever done.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Earth Returns for Electric Tramways. By H. F. Parshall, member. Paper read April 28th, 1898.

(*Concluded from page 635.*)

1. *For Conductivity* the Chicago bonds in the different tests have shown practically 100 per cent. of the conductivity of pure copper. A flexible Crown bond showed only 93 per cent. conductivity. The Columbia bonds in the cases tried showed about 90 per cent. conductivity.

2. *Resistance due to Contacts.*—Measured from the potential difference between two points very close together, one on the bond terminal, the other on the steel. Experiment showed the following results:—

Bond.	Test.	Resistance per bond (2 terminals).	Resist'nce of 176 joints, or per mile with 30-ft. rails.	Remarks.
		Ohms.	Ohms.	
Chicago Bonds ... ⅝-in. terminals in ½-in. web. 1·37 sq. in. contact area.	1	0·00000197	0·000347	Bond and hole very clean.
" " "	2	0·00000215	0·000379	" "
" " "	3	0·0000025	0·000440	Bond not cleaned; hole freshly reamed, but oily.
" " "	4	0·0000080	0·00141	Bonding not supervised.
Crown Bonds ... ⅝-in. terminals in $\frac{7}{16}$-in. web. 1·2 sq. in. contact area.	5	0·0000080 0·0000028		" "
Total ...		0·0000108	0·00190	
Crown Flexible Bond ⅝-in. terminals in $\frac{7}{16}$-in. web. 1·2 sq. in. contact area.	6	0·0000422 0·0000518		Bonding not supervised; bonds afterwards found to have been put in rusty hole.
Total ...		0·0000940	0·0165	
Columbia Bond ... In ⅝-in. hole in ½-in. web. 1·37 sq. in. contact area.	10	0·0000072	0·00127	Hole clean; bond untouched.
" " "	12	0·0000095	0·00167	" "
" " "	13	0·0000077	0·00136	Hole 4 days old; bond untouched.

Tests 4, 5, and 6 show that want of care in bonding may lead to serious increase in contact resistance.

From the tests made it may be said generally that bonds properly applied—that is, clean bonds in bright reamed holes, put in with a proper fit with a drift driven square—have practically negligible contact resistance. Experiments showed that at at least 100 amperes per square inch the drop in the contact surface was inappreciable compared with that in the bond and in the rail. The same was found true with bonds—samples of which are exhibited—that have been in use for over two years, when the current-density has been limited as stated. Experiments on this point have been carried out to a considerable extent, since it has been frequently stated that the contact resistance is a very appreciable factor, and that it can be greatly lessened by amalgamating the surfaces. This will not be the case except when there is carelessness in putting the bonds in place.

3. *Gathering.*—The current may be supposed to flow uniformly through the rail at all parts, a foot or so from the ends or from bonds. At a bond, however, it has to gather, and it is scarcely to be expected that, say, 16 inches of rail terminating at a bond should show the same resistance as 16 inches in the middle of the rail.

Tests on a bar of steel 3 inches × ½ inch showed "gathering" at the two bond terminals added resistance equivalent to a total of about 1 inch of the bars.

Tests on an 83-lb. rail showed "gathering" resistance equivalent to 3·4 inches of rail at each contact, or a total of 6·8 inches per joint.

Joints.

The conductance of the joints depends, as stated, on both bonds and fish-plates.

The first have been discussed already.

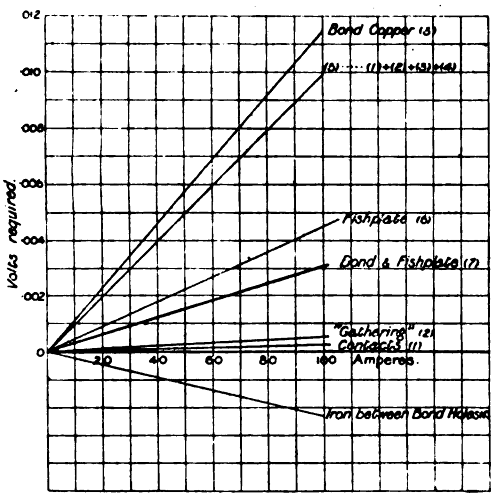
The second have a very appreciable effect, even with rails that have been in use for some time.

The following table shows the results of a number of tests made partly in the laboratory and partly on track in use:—

Laboratory tests.	Additional resistance due to joint. Ohms.	Inches of rail.	Resistance of 176 joints per mile, or with 30-ft. rails.
83-lb. rail; six tests; no bonds, fish-plates uncleaned, and not fully tight.	0·0000095 to 0·000081	10 to 87	0·0017 to 0·0143
Average	0·000039	34	0·0068
Single 0000; 30-in. bond only (calculated) ...	0·000101	109	0·0178
83-lb. rail, with one 30-in. Crown 0000 bond, plates well tightened...	0·0000024	3	0·00041
Same with fish-plate removed	0·000106	114	0·0187
This bond had too great contact resistance. See Contact Test No. 5.			
Tests on Rails in Use.			
76-lb. rail; one 30-in. 0000 Chicago bond and fish-plates.	0·0000307 to 0·0000622	32 to 65	0·0054 to 0·001
Four tests made without disturbing track *average*	0·000043	45	0·0076
76-lb. rail as above (track 2½ years old); four tests	0·0000275 to 0·0000843	28 to 80	0·0048 to 0·0148
Average	0·000046	48	0·0081
Single 30-in. 0000 Chicago bond only (calculated)	0·000103	114	0·0181
Old 65-lb. rail; one 30-in. 0000 Chicago bond, fish-plates not tight ...	0·000069	57	0·0121
Above with fish-plates removed	0·000090	74	0·0158
Above with fish-plates replaced and well tightened	0·0000473	39	0·0083
New 90-lb.; two 32-in. 000 Chicago bonds and plastic to one fish-plate	0·0000081 0·0000040	10 5	0·0143 0·0071
Average	0·0000060	7½	0·0105
Fish-plate added to conductivity.			

The above values show that the contacts had not deteriorated in any way in the two and a half years of use. Some of the rails were very old, but the fish-plates, which were not fully tight, showed bright patches of metal at places of contact with rail. On replacing plate and re-bonding, the joint was equivalent to 39 inches of rail.

A second rail tested without fish-plate showed also *no* deterioration of the bonding.



Volts required by various elements of joint in 80-lb. rail bonded with 1½-inch plastic bond to one fish-plate only.

Fig. 2.

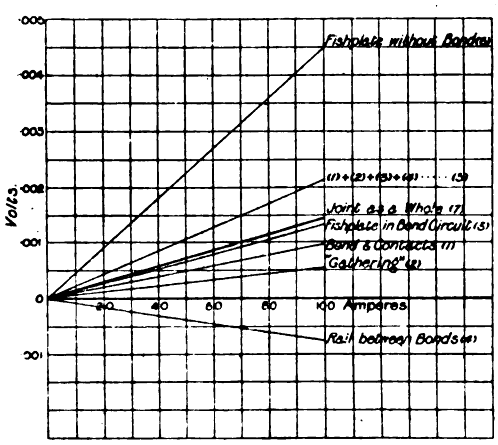
Some 66½-lb. rail laid on another line recently bonded showed joint resistances equivalent to 9½ inches to 28 inches in four different cases.

Plastic Bonds.

1½-inch hole in the cork receptacle between fish-plate and rail filled with plastic material.

Description.	Increased resistance due to joint.	Inches of rail.	Increased resistance of 176 joints, or per mile with 30-feet rails.
	Ohms.		
83-lb. rail bonded to one plate only; both plates separated by paper from rail	0·0000213	21	0·00375
Do., but bonded to both fish-plates; plates not very tight	0·0000126	14	0·00222
Do.; plates a little tighter ...	0·0000123	14	0·00217
Do.; plates very tight; brown paper still between plates and rails ...	0·0000117	13	0·00206
Do.; brown paper removed; plates tightened very hard up	0·0000083	9	0·00146

From the above, it seems safe to take the resistance through fish-plates as equivalent to some extra 50 inches of rail, and to take this resistance as in parallel with the copper or plastic bonds used in addition. Curves can then be constructed for any particular system of bonding similar to those of fig. 3, which gives P.D. for the various elements of a joint of 80-lb. rail bonded with a single 0000 B. & S. copper bond 30 inches long with 7/8-inch terminals.



Volts required by various elements of joint in 80-lb. rail bonded with a single 30-inch 0000 copper bond, with ⅞-inch terminal in $\frac{7}{16}$-inch web.

Fig. 3.

The contact and gathering resistances are added to the bond copper resistance, and the resistance of the iron between the bond holes deducted. This gives Curve No. 5. The resistance so found is taken as in parallel with the fish-plates' resistance and curve (7) calculated for the whole joint. The volts so found must be multiplied by the number of joints per mile, and added to the volts required to drive the current through a mile of jointless rail.

Apparatus Employed in Testing.

All resistances were found by measuring the potential difference between two points on the rails when a constant current of 30—150 amperes was passed through the latter. A standard resistance of 0·0000398 was placed in the same circuit, and the fall of the potential across this compared with that across the two points on the rail. The places at which current was led in and out of the rail were always at some distance from the points between which the potential difference was taken. Where measurements were made upon the actual track, current was supplied from an accumulator placed upon a car brought up to the spot. Current was led from this to a point in the middle of the rail to be tested, and was led out some 5 or 6 feet on the other side of a rail joint. The fall of potentiel was then measured between two points inside those by which the current was led into the rail, and also between two points on the same rail outside the places at which current was led into it. The standard resistance was included in the circuit, and comparisons taken with this at each stage. From these two measurements the resistance of the rail could be calculated as long as no cross bonds occurred upon the part of the track actually under test. To measure the resistance of the joints, a joint was included between the two points of which the potential difference was taken, and this compared with the potential difference between two points at a similar distance apart on the continuous rail. It was found extremely important in some cases to reverse the current both in the rail and the potentiometer, since with the small potential difference measured thermo-electric effects were very liable to disturb the results.

In certain experiments a current was passed into the rails at one end of the track, and taken out at the other. The current in the rails at intermediate points could be measured by taking the difference of potential between two points on the same metals which had been tested for resistance as above. This had, of course, to be done for all four lines of the double track. The volts used to drive current through the whole length of track were measured by making use of the test wires. The potentiometer was employed for this purpose also, and the results may be taken as correct, within the limits of correctness of calibration of the instrument itself, which was supplied by Elliott Brothers.

Notes on Electric Tramways. By Major P. Cardew, R.E., and A. P. Trotter, Members. Read April 28th, 1898.

The accompanying note on return feeders for electric tramways has been forwarded to me by Mr. A. P. Trotter, and as it contains a neat, graphical method for determining the fall of potential in the return with uniform distribution of current, and the proper points of application of return feeders, I think it may prove interesting in connection with Mr. Parshall's paper.

As Mr. Trotter alludes to previous suggestions of my own on this subject, I also forward a note which was prepared by me in May, 1894, and sent to the South Staffordshire Tramways Company, advocating the automatic regulation of this fall of potential.

P. Cardew.

Note on Return Feeders for Electric Tramways. By A. P. Trotter, Member.

While great ingenuity has been expended in designing bonds for electric tramway rails, and while these bonds, assisted in some cases by bare copper conductors laid between or near the rails, form a considerable item in the cost of building a line, little attention has been paid to the use of return feeders. The use of return conductors, provided with a small dynamo, was suggested by Major P. Cardew several years ago, and it has been independently proposed by Mr. G. Kapp. The system has been in use for some time in Geneva, and has recently been applied with success to the extension of the Bristol tramways.

The best mode of arranging such return conductors does not appear to have been described, and the present communiction is intended to afford an opportunity for discussing it.

Assume a tramway line with passing places, five miles long, and 10 cars running. The most even distribution will, of course, be when they are equidistant, and a less even distribution is not likely to occur than when all the cars are in pairs at passing places. Let each car take 20 amperes, and let the resistance of the bonded rails be $\frac{1}{20}$ ohm per mile. When the cars are evenly distributed, half a mile apart, the rail resistance between each pair is $\frac{1}{40}$ ohm, and with 20 amperes the drop on half a mile of rails is ½ volt.

The series is as follows:—

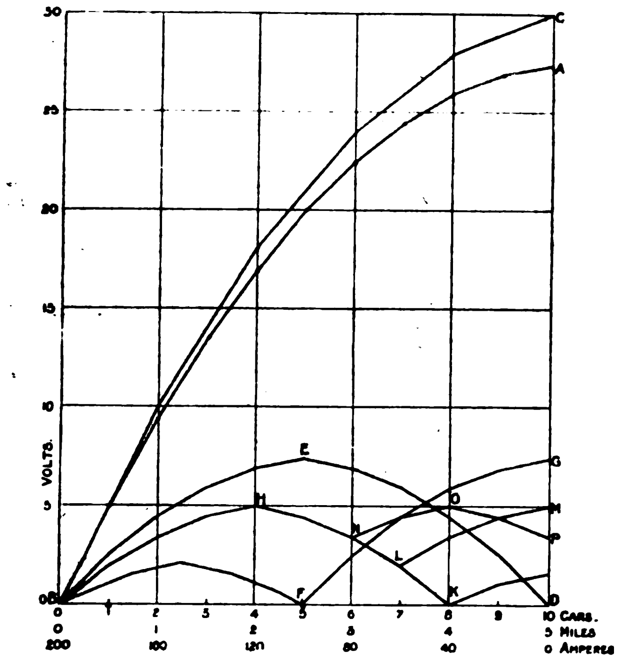
Cars ...	1	2	3	4	5	6	7	8	9	10	works.
Volts ...	0	½	1½	3	5	7½	10½	14	18	22½	27½

The first car is supposed to be at the extreme end of the line. The case is an extreme, but not an imaginary one. The large total fall of 27½ volts over five miles should, of course, be reduced in the first instance by more ample bonding, but the example serves the better to illustrate the problem.

When the cars are all passing in pairs, at a mile apart, the drop due to 40 amperes over one mile is 2 volts. The diagram shows the distribution for these two cases; the line, A B, showing the fall of volts for 10 cars evenly spaced half a mile apart, and the curve, C B, the fall for cars in pairs a mile apart. Mathematically, the point, A, is the origin of the curve, to which the line, A B, is an approximation; but as it is not intended to treat the problem mathematically, the point, A, is, for convenience, placed at the top right-hand corner.

The volts in the two cases differ so little, compared with the fluctuations of energy on an electric tramway, that this question of distribution of the cars will not be referred to again, but the line, A B, will be considered as typical.

The return feeder method by which this fall of volts may be reduced, consists in connecting a feeder to some point on the rails, and tapping off some of the return current. The conductivity of the feeder is not relied upon for this, but a dynamo, acting as a negative



"booster," may be said to suck the current back. By this means the point at which the feeder taps the rails may be brought down to zero-potential, or might be made negative to the generating dynamo.

The problem to be considered is—(*a*) To reduce the volts below a fixed maximum; (*b*) to use as little copper as possible; and (*c*) to use as little energy as possible.

Disregarding the two latter conditions, a simple plan would be to run a feeder the whole length of the line, and to reduce the volts to zero at the far end of the line, D. The distribution is then symmetrical; half of the current goes to the generating dynamo, and half to the return feeder. To draw the curve of distribution, cut out a piece of card to the shape of the curve of volts A B, and, fitting the vertical axis to the ordinate 5, place it so that it passes through the point D. Turn the card over, and complete the curve through A in the same way. The maximum volts, at the point E, are 7½.

But there is no occasion to reduce the volts at the end of the line to zero, and there is evidently a maximum expenditure of copper and of energy in the feeder. The middle point of the line is evidently not the best point to tap, for the volts would be distributed as shown by the line B F G, which may be easily drawn by means of the template. Here the maximum is, as before, 7½, and the volts near the works are unnecessarily low, viz., 2 volts at 1¼ miles out. It is clear from the line B F G, that the feeder would draw off three-fourths of the total current. It would be still worse to tap the rails at the point at which the volts rise to one-half the maximum, viz., at about 1¼ miles from the works.

Starting now in a different manner, let it be given that the maximum volts are not, under ordinary circumstances, to exceed 5, allowing a margin of two below the Board of Trade limit. Draw the line B H by means of the template, and fitting the template so that its axis is vertical, that the top touches the line of 5 volts at the point H, and that it passes through the point B. Turn it over and draw the line H K. But as it is not necessary, from the "undertakers'" point of view, to reduce the volts to zero at the point K, set the template again, allowing 5 volts at the end of the rails at the point M, and, drawing the line backwards, it is found to intersect the line H K at L. The volts at this point are 2, and this is the best that can be done with a single return feeder. This feeder will be 3½ miles long, and will draw off 0·65 of the current.

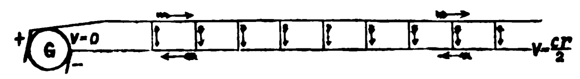
Note on Electric Tramways. By Major P. Cardew, R.E., Member.

It is, I believe, generally admitted that where the rails are used for the collection and partial transmission of the return current, the best means of preventing injurious action on pipes is to minimise the difference produced by the current between the potential of the uninsulated return at different points, and between any part of such return and the earth. On account of the resistance offered by all conductors to the current, the transmission of a current by means of a conductor causes a fall of potential throughout the length of the conductor, the difference of potential being greatest between the ends of the conductor.

This is the case whether the whole current is transmitted throughout the length of the conductor, or is fed in (as in the case of a tramway line) at different points along the length, provided that the direction of the current throughout the length of the conductor is the same, which must be the case when this conductor forms the only path for the current back to the generating machine.

But if additional conductors are used to take current from the main conductor, which receives the current distributed along its length back to the generator, the greatest difference of potential in

Fig. 1.



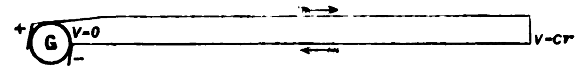


Fig. 2.

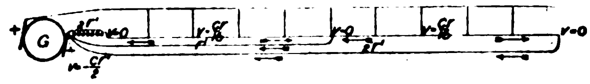

Fig. 3.

Note.—In the above figures *v* indicates potential with regard to earth.

this main conductor may no longer exist between the ends of the conductor, and the amount of this difference may be greatly reduced. The extent of the reduction will depend upon the position of the junctions effected and the resistance in the auxiliary conductors.

If we assume, for example, *n* auxiliary conductors, all of equal resistance, connected to the main conductor at equal distances throughout its length, and one from the extreme end of the main conductor of twice the resistance of the others, a resistance equal to this last being interposed between the generator and the near end of the main conductor, then with a uniform distribution of current all the points of junction will be at the same potential, and the extreme difference of potential between any points of the main conductor will be reduced to $\frac{1}{4(n+1)}$ of what it would be without these auxiliary conductors or feeders.

Thus with one feeder to the distant end alone the fall of potential in the main conductor can be reduced to one-fourth, and with a feeder to the centre as well, to $\frac{1}{12}$th, of that due to the same distributed current without feeders; and it will be seen that under such conditions the variation of potential in the main conductor can be reduced to any required limit.

But, unless these feeders are of very large cross section and conductivity compared with that of the main conductor, there will still be a considerable fall of potential in them, and in consequence a considerable difference of potential between the main conductor and the terminal of the generator to which it is connected by means of the feeders.

In place of adjusting the resistances of all feeders to equality, varying E.M.Fs. may be introduced into each feeder, proportionate to its resistance, and thus the potential of all feeding points may be kept the same as that of the terminal of the generator, if desired.

In considering the application of the feeding arrangements described above to the special case of minimising the leakage to earth from the rails of a tramway used as a return circuit, it must be borne in mind that, although the load under normal conditions may be fairly uniformly distributed, yet the exigencies of traffic may require far more current to be supplied to one section of the line than its proper share, other sections at the same time being lightly loaded.

The position and slope of the various gradients on the line also considerably affect the distribution of current in the rails. The number of cars at work, and, therefore, the total load, also generally varies during each day's running, and from day to day.

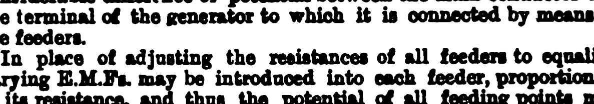

Fig. 4.

Note.—*v* indicates potential with regard to earth; *e'* and *e''*, auxiliary E.M.Fs

The disposition shown in fig. 4 can be adapted to meet the special requirements; but unless the auxiliary E.M.Fs. are continually adjusted to the variations of load, both as regards amount and distribution, the arrangement must be defective at times.

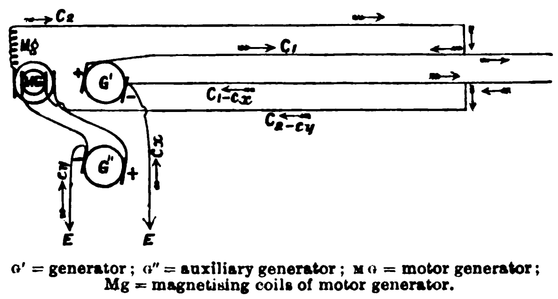
In order to provide auxiliary E.M.Fs. for the efficient working of the feeders to the return, automatically adjusted to the requirements, I would suggest the following arrangement:—

Let the tramway be divided into several sections according to its length and the amount of traffic gradients, &c.

Let there be two insulated feeders for each such section—one for the line, and one for the return; the latter being connected to an uninsulated conductor as provided in Regulation 4.

Let the current in these feeders pass through a "motor generator" at the generating station, the "field magnets" of which are excited by the current to line alone, while the armature is wound with two circuits—one for each current, so as to oppose each other—the circuit through which the current to line passes being made slightly the more powerful. The motor generator will then revolve as urged by the line current, and will generate an auxiliary E.M.F. for the return current.

The generator for each feeding circuit should be of rather higher E.M.Fs. than that supplying the near end of the line and return; but, as the extra volts will be taken by the motor generator in the station, there will be no need to exceed the limit allowed by the Board of Trade on the line outside.



G' = generator; G'' = auxiliary generator; M G = motor generator; Mg = magnetising coils of motor generator.

Fig. 5.

The expense involved may probably prevent the adoption of any such system in its entirety at present, but it possesses the advantage that it can be adapted to existing tramways, and a pair of feeders run to any part where the difference of potential from earth of the rails is found to be excessive.

Such an arrangement with one pair of feeders is sketched in fig. 5.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

Rules made by the Board of Trade with Respect to Applications for Licenses and Provisional Orders, &c.

Consent of Local Authorities.

Rule I.—No application for a license or for the renewal of a license will be entertained unless proof of the consent to such application of every local authority having jurisdiction within the proposed area of supply is given to the Board of Trade.

Rule II.—No application for a provisional order (other than an application from the local authority of the district) will be entertained by the Board of Trade unless proof of the consent of every local authority having jurisdiction within the proposed area of supply to the grant of the order, or a request from the applicants asking the Board of Trade to dispense with the consent of such local authorities as have not consented and giving the reasons for such request, is deposited with the Board of Trade within the time limited for proving compliance with the provisions of the Electric Lighting Acts and these rules.

Rule III.—At the time of proving the consent of the local authority to an application for a license or renewal of a license or to the grant of a provisional order, the applicants must deposit with the Board of Trade copies of any agreement entered into with the local authority relating to such consent.

Rule IV.—Where the consent of any local authority is required to any application for a license or the renewal of a license or to the grant of a provisional order, such consent must be given by a resolution passed at a meeting of the local authority held after previous notice of the same and of the purpose thereof has been given in the manner in which notices of meetings of such local authority are usually given; and the fact that such a resolution was duly passed must be proved by a certificate signed by the secretary or clerk to such local authority reciting copies of the notice and of the resolution, and declaring that the notice was duly given and the resolution duly passed.

Notices.

Rule V.—Any local authority, company, or person intending to apply for a license or provisional order must at the time of lodging their memorial with the Board of Trade in the case of a license, and on or before November 1st in the case of a provisional order, give notice in writing of their intended application to every local authority, company, or person authorised to supply electricity under statutory powers within the district to which the proposed application refers.

Rule VI.—Except in the case of an application by the local authority for the district a provisional order will not be granted by the Board of Trade except to the body or person by whom the notice required by Section 4, Sub-section 1, of the Electric Lighting Act, 1882, was given.

Rule VII.—In any case where a local authority, company, or person is required by the Acts to give notice to the local authority of the district, "in such manner as the Board of Trade may direct or approve," such notice must be given in writing, and must be served, either by leaving the same at the offices of the said local authority, on or before the appointed day or by forwarding the same by post in a registered letter so that the same would in ordinary course of post be delivered on or before the appointed day.

Application and Deposits.

Rule VIII.—Every application for a license or provisional order must be made by memorial signed or sealed by, or on behalf of, the the applicants, headed with a short title descriptive of the proposed undertaking (corresponding with that at the head of the advertisement hereinafter mentioned, *see* Rule XIII.), addressed to the Board of Trade. With the memorial must be deposited six copies of the draft license or order, as applied for, with the schedule or schedules (if any) referred to therein.

Rule IX.—The deposited copies of the draft license or order must be in print. They must be printed on one side only and each schedule annexed must begin a new page.

The names and addresses of the Parliamentary agents or solicitors for the license or order must be printed on the outside of the draft.

There must be a notice at the end of the draft stating that objections are to be made by letter addressed to the Board of Trade, marked on the outside of the cover enclosing it "Electric Lighting Acts," and that such letter is to be sent to the Board of Trade in the case of a provisional order on or before January 15th next ensuing, and in the case of a license within two months from the date of the newspaper containing the first advertisement of the application, and that a copy of such objections is to be forwarded to the Parliamentary agents or solicitors for the license or order.

The draft must contain amongst other things:—

1. The address and description of the applicants.
2. A description of the proposed area of supply.
3. A statement of the purposes for which a supply is to be given, viz., any or all of the public or private purposes specified in Section 3 of the Electric Lighting Act, 1882.
4. Provisions concerning the breaking up of streets, railways, and tramways, where powers are sought to be obtained by the license or order for those purposes.
5. Conditions of supply.
6. Provisions for securing the safety of the consumer and of the public from injury by shock, fire, or otherwise.
7. Provisions for enforcing the performance by the undertakers of their duties in relation to the supply of electricity and for the revocation of the license or order where the undertakers fail to perform such duties.

The applicants must also deposit a sufficient number of printed copies of the draft license or order at offices in London and within the proposed area of supply to be specified in the advertisement hereinafter mentioned, *see* Rule XIII., such copies to be there furnished to all persons applying for them, at a price of not more than 1s. each.

Rule X.—The applicants must also deposit at the Board of Trade a published map of the district on a scale of not less than 6 inches to a mile, or if there is no published map, then the best map procurable, showing the boundaries of the proposed area of supply, and the streets in which it is proposed that electric lines should be laid down within a specified time.

They must also deposit a copy of the said map for public inspection—

> In England or Ireland, in the office of the clerk of the peace for every county, riding, or division, and of the local authority of every district.
>
> In Scotland, in the office of the principal sheriff clerk, for every county, district, or division, and of the local authority of every district

in which the proposed area of supply or any part thereof is situate.

Such deposits must be made in the case of a license when the memorial is lodged, and in the case of a provisional order on or before November 30th.

Rule XI.—There must also be deposited with the memorial:—

1. A list of the local authorities in whose districts the area of supply is situate.
2. A list of the local authorities, companies, or persons (if any) authorised to supply electricity under statutory powers within the area of supply.
3. A list of the streets not repairable by a local authority and of the railways and tramways (if any) which the applicants propose to take powers to break up.
4. A list of the canals and navigable rivers (if any) within the proposed area of supply.
5. A statement of the capital proposed to be expended and employed in connection with the undertaking, and the mode in which such capital is to be provided, or in the case of an application by a local authority a statement of the sums proposed to be expended.
6. If the applicants are a company incorporated under the provisions of the Companies' Acts, a copy of the memorandum and articles of association.
7. A fee of £50 by cheque payable to an "assistant secretary of the Board of Trade" to cover ordinary expenses. If in consequence of inquiries or otherwise additional expense is incurred, the amount will be charged to the applicants and must be paid by them in addition to the ordinary fee.

Applications under Section 13 of Electric Lighting Act, 1882.

Rule XII.—Where the undertakers under any license, order, or Special Act desire the written consent of the Board of Trade under

Section 13 of the Electric Lighting Act, 1882, to enable them to break up any street not repairable by a local authority or any railway or tramway which they are not empowered to break up under such license, order, or Special Act, application for such consent must be made by memorial, and the memorial must specially request such consent and must describe accurately the street, railway, or tramway which they propose to acquire power to break up.

PROCEDURE.

Rule XIII.—Applicants for a license or provisional order must proceed as follows, subject in the case of a license to the application having been previously entertained by the Board of Trade, *vide* Rule I.:—

They must publish notice by advertisement of their application, or in the case or a provisional order, of their intended application, and every such advertisement must contain the following particulars:—

1. The objects of the application.
2. The address and description of the applicants.
3. A description of the proposed area of supply.
4. The names of the streets in which it is proposed that electric lines should be laid down within a specified time.
5. A list of the streets not repairable by a local authority and of the railways and tramways (if any) which the applicants propose to take powers by the license or order to break up.
6. The address of an office in London, and another office within the proposed area of supply, at which printed copies of the draft license or order when applied for, and of the license or order when made, can be obtained at a price of not more 1s. each.

The advertisement must be headed with a short title, descriptive of the undertaking (corresponding with that at the head of the memorial), and it must state that every local or other public authority, company, or person desirous of bringing before the Board of Trade any objection respecting the application must do so by letter addressed to the Board of Trade, marked on the outside of the cover enclosing it "Electric Lighting Acts," in the case of a provisional order on or before January 15th next ensuing, and in the case of a license within two months from the date of the newspaper containing the first advertisement, and that a copy of such objection must also be forwarded to the Parliamentary agents or solicitors for the license or order.

The advertisement must be inserted once at least in each of two successive weeks in one and the same newspaper, published and circulating in the proposed area of supply, or in such other newspaper as the Board of Trade may direct; and once at least in the London, Edinburgh, or Dublin Gazette, accordingly as the proposed area of supply is situate in England, Scotland, or Ireland.

Rule XIV.—If any local or other public authority, company, or person desires to bring before the Board of Trade any objection respecting an application for a license or a provisional order they must do so by letter addressed to the Board of Trade, marked on the outside of the cover enclosing it "Electric Lighting Acts," in the case of a provisional order on or before January 15th next ensuing, and in the case of a license within two months from the date of the newspaper containing the first advertisement of the application. A copy of the objection must also be served upon the Parliamentary agents or solicitors for the license or order. If any local or other public authority, company, or person desires to have any clauses or other amendments inserted in the license or order, they must deliver the same to the Board of Trade, and also to the Parliamentary agents or solicitors for the license or order, on or before the time limited for bringing objections.

Rule XV.—When a license or provisional order has been granted by the Board of Trade and delivered to the applicants, they must forthwith deposit printed copies for public inspection in the offices specified in Rule X., and must supply copies to all persons applying for the same, at a price of not more than 1s. each, and must further publish the same as the Board of Trade may direct.

Rule XVI.—Where in a license or provisional order granted by the Board of a deposited map is referred to, the promoters must within one month from the grant of the license or order deposit at the Board of Trade a published map on a scale of not less than 6 inches to a mile, or if there is no published map then the best map procurable showing the area of supply coloured to correspond with the description in the license or order. The map must be mounted on linen and must be certified as correct as regards their respective districts by the clerk or surveyor to every local authority having jurisdiction within the area of supply.

SPECIAL PROVISIONS AS TO PROVISIONAL ORDERS.

Rule XVII.—In the case of provisional orders the following additional regulations must be observed:—

1. The advertisements must be inserted in October or November.
2. A copy of the advertisement must be deposited on or before November 30th at the Board of Trade and at the offices specified in Rule X.
3. The memorial must be lodged on or before Decembr 21st.
4. The Parliamentary agents or solicitors for the order must be prepared to prove compliance with the provisions of the Acts and these rules by January 15th, and all such proofs must be completed on or before February 22nd. Six days' notice will be given of the day and hour at which such agents or solicitors are to attend for the purpose of the Board of Trade, and printed forms of proof will accompany the notice. These forms must be filled up and brought with the requisite documents to the Board of Trade at the time fixed for receiving proof.

HENRY G. CALCRAFT,
Secretary.

The Board of Trade,
August, 1890.

NOTE.—When applications for provisional orders authorising the supply of electricity within the district of any local authority are received by the Board of Trade from such local authority, and also from any other authority, company, or person, the Board of Trade will give a preference to the application of the local authority of the district in every case where, in the opinion of the Board of Trade, no special circumstances exist which render such a preference inexpedient.

In cases of applications for a license, renewal of license, or provisional order, to which objection is made by any person locally interested, the Board of Trade will, if they consider it expedient, hold a local inquiry, of which due notice will be given.

THE GAS ENGINE IN AMERICAN PRACTICE.

MR. GEORGE RICHMOND, who writes in the *Engineering Magazine*, is, perhaps, as well versed in gas engine practice as anyone in America. Up to the expiry of the Otto patent the progress of gas engines was slow in America, partly because gas was dear, and largely because gas engines were costly.

The lapse of the patent flooded the country with cheap engines, low in strength and overrated in capacity, from which a reaction has now set in, and substantial, well-drawn engines appear reasonably certain to be soon sold in large numbers. And it is in producing electricity that Mr. Richmond foresees a brilliant future, especially with its congener, the oil engine, for the electric lighting of country houses and villages, for the average conception of America as a country of huge and hideous cities is by no means the whole truth. We have in mind as we write a little community—half village, half a mere locality—which is by no means far removed in character from that peaceful quiet which characterises some of the off-track villages of our own Sussex.

While our author refers to the Diesel motor as a brilliant success as compared with the Brayton engine, which it resembles in its operation except for its intended isothermal combustion, he states its cycle to be theoretically inferior to that of Brayton, though rendered a success by the fact of compressing to ignition temperature. Evidently Mr. Richmond is not to be caught with chaff, and has a very poor opinion of the "ripening and cooling spark" twaddle on which the Kane Pennington motor was sold to British investors. He seems honestly ashamed of this motor being of American origin, and therefore publishes cuts of really sound American engines.

On the other hand the Gardie engine, taken over to America about the same time from Europe, was really sound, but was wrecked by stock jobbing. It was Americanised as the Bates triple thermic motor, and in its operation both gas and air were separately compressed and heated thereby to about 390° F., and being then passed through regenerators to 750° F., the gas and air being still separate. They are then discharged to the motor cylinder in thin jets or layers alternated—we are not told if this stratification was really secured. On ignition by contact with an igniter (? a tube), the temperature rises to 2,730° F., the products of combustion expand, and the spent gases, still hot, pass out *viâ* the regenerators. However, good or bad, a $5,000,000 company was too much for this motor, and forthwith close on its heels, comes the Diesel motor, with an advance syndicate of a modest million dollars only. This motor he looks on as a triumph of mechanical work, with its 35 atmospheres compression and its 75 per cent. efficiency.

In the Otto engine, pressures of compression up to 38, 66 6 and 87·5 lbs. above the atmosphere gave 17, 21 and 25 per cent. efficiency, and 95 lbs. was recorded by Mr. Clark to have given 30 per cent. efficiency. The Diesel has shown 34 per cent. at 450 lbs. compression, a result disappointing, and only satisfactory as a mechanical performance; the net efficiency, after paying for the various complications, being poor for such a high pressure.

In the case of the Otto engine with 95 lbs. compression above quoted, the initial pressure was 310 lbs., so that, as regards mechanical difficulties, the Diesel may be assumed the more difficult with its 450 lbs. The Diesel engine only modifies Beau de Roche's cycle in the ignition period; it does not closely follow the Carnot cycle, at which it aims.

Our author considers that the belief in the advantage of the isothermal combustion arises from a misconception of the doctrine of Carnot, or rather a misapplication of it, and he does not think the isothermal expansion of the Diesel cycle is even its most valuable feature, while the difficulty in securing it will be very great.

The German type of gas engine was the first to be taken up in America, but the British type now seems to be gaining ground. In the gas engine, if anywhere, our national characteristic of solidity and weight ought to tell favourably. While various ingenious arrangements for direct connection have been tried, Mr. Richmond considers the link belt, run slack with a fly-wheel on the dynamo, as there ought always to be, will hold its own until a more simple system of direct connection is found.

The enormous amount of money spent in getting up new gas engines is attributed to the fact that the new designer starts out with a great contempt for all previous work. About £2,000 is spent in teaching the new man elementary ideas, a second £2,000 in trying revolutionary modifications, and the third in getting the engine to run as economically as others in the market. Our own personal observation tells us that many light-built engines run exceedingly well—when new—but we can recall no old-established gas engine that is not very heavy to-day about the cylinder. Mr. Richmond appears surprised at scientific Germany being not exempt from the above cycle of £2,000 ideas. He instances the first Diesel engine as being built without the water jacket, as compounding being now in course of being experimented upon at great expense, while to these ancient and exploded fallacies is being added the isothermal combustion "elaborated with a quasi-scientific and solemn minuteness intended to be admired rather than understood." But perhaps Mr. Richmond does not know his Shakespeare. If he does, when he gets a full-blown Diesel, minus jacket and with the many atmospheres of compression, he may think it "like a German clock still a preparing; ever out of frame; and never going aright, being a watch. But being watch'd that it may still go right."

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. THOMPSON & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*

9,466. "The compact electric switch." P. H. BRANT. Dated April 25th.

9,475. "Improvements in and connected with arc lamps." F. R. BOARDMAN. Dated April 25th.

9,482. "Improvements in apparatus for freeing, lighting, and extinguishing gas burners at a distance by means of electricity." P. L. GUYENOT. Dated April 25th.

9,493. "Improvements in or relating to 'starting boxes' or combined rheostats and automatic cut-outs for electric motors." A. J. BOULT. (F. E. Herdman, United States.) Dated April 25th.

9,504. "Improvements in operating mechanism for the switches of electric railways." J. W. MACKENZIE. (C. W. Squires, United States.) Dated April 25th.

9,511. "Improvements in rheostats for the graduated control of electrical resistance, particularly applicable to the production of theatrical luminous effects." C. E. CLEMANCON. Dated April 25th.

9,534. "Improvements in incandescent electrical devices." W. L. WISE. (C. Hubert, United States.) Dated April 26th.

9,548. "Improvements in electric arc lamps respecting arc striking arrangement." P. SPIES. Dated April 26th. (*Complete.*)

9,581. "Improvements in coin-freed or prepayment apparatus for supplying electricity." A. G. IONIDES. Dated April 26th.

9,607. "Improved electric arc lamp." J. T. TSCHIERET. Dated April 26th.

9,637. "Improvements in process for the production of chemical compounds by electrolysis." J. W. RICHARDS and C. W. ROEPPER. Dated April 26th. (*Complete.*)

9,638. "Process for manufacturing metallic sulphides electrolytically." J. W. RICHARDS and C. W. ROEPPER. Dated April 26th. (*Complete.*)

9,677. "Improvements in swing joints or ceiling connections for carrying suspended electric light fittings." VERITYS, LTD., and P. G. EBBUTT. Dated April 27th.

9,692. "Improvements in resistance apparatus for regulating electromotors." SIEMENS BROS. & Co., LTD. (Siemens & Halske, Aktien-Gesellschaft, Germany.) Dated April 27th. (*Complete*)

9,712. "Improvements relating to telephones and to circuit arrangements and relays therefor." O. J. LODGE. Dated April 27th.

9,714. "Improvements in portable electric batteries and electric lamps." G. F. EMERY. Dated April 27th.

9,723. "Improvements in electric current switch gear." L. ANDREWS. Dated April 27th.

9,739. "Improved means and apparatus for electrolytically decomposing salts of the alkaline and earthy metals or other substances containing them for the manufacture of caustic bleaching powder chlorine, or other products contained in them." F. H. BOWMAN and F. E. BOWMAN. Dated April 28th.

9,778. "Improvements in plates for electric accumulators." M. BERNSTEIN. Dated April 28th. (*Complete.*)

9,779. "Relating to improvements in testing and projecting apparatus used in conjunction with telephone, telegraph, or other electrical circuits." D. SINCLAIR and W. AITKEN. Dated April 28th. (*Complete.*)

9,789. "Improvements in, and connected with, electroliers and incandescence electric lamp pendants." H. HIRST and J. H. COLLINGS. Dated April 28th.

9,802. "An improved system and means for driving newspaper printing, or like machines, at variable speeds by electric motors." W. A. CLATWORTHY, W. H. HOLMES, A. HOLMES, J. H. HOLMES, L. W. HOLMES, and E. HOLMES. Dated April 28th.

9,811. "Improvements in, and relating to, dynamometrical apparatus." H. BOURON. Dated April 28th. (*Complete.*)

9,844. "Improvements in adjustable shade supports for electric and the like fittings." W. H. STURGE. Dated April 29th.

9,877. "Improvements in electric switches." J. G. DIXON. Dated April 29th.

9,881. "Improvements in means and devices for electrically lighting coin-freed apparatus for displaying pictures." A. W. WITT and M. W. STIEBMAN. Dated April 29th. (*Complete.*)

9,912. "A new and improved chimney for incandescent gas, electric, and oil lights." M. ALTMAN. Dated April 30th.

9,921. "An electric brake." F. WISE. Dated April 30th.

9,960. "Improvements in or relating to electric meters." A. J. BOULT. (E. L. G. Cauro, Italy.) Dated April 30th. (*Complete.*)

9,983. "Improvements in or relating to telephonic apparatus." R. GUNTHER, E. VON KRONMYSTH, jun. Dated April 30th.

ELECTRICAL PATENTS OF 1884, EXPIRING IN MAY, 1898.

We are informed by Messrs. W. P. Thompson & Co. that about 96 applications for electrical patents were filed in the month of May, 1884. Out of these only three have been allowed to run their full length of term, viz., 14 years, and being of considerable interest we give short abstracts of them below:—

7,668. "Electric meter." J. S. RAWORTH. Dated May 13th, 1884. Relates to current meters. In one form of the instrument, for use as an electro-dynamometer, a pivoted iron spindle provided with two iron arms projecting from its ends in opposite directions, is surrounded by a low resistance coil, portions of which are parallel to the arms. When a current passes through the coil the spindle becomes magnetised together with its prolongations, which are then deflected by the portions of the coil which are parallel to them in opposition to a volute spring, one end of which is connected by an arm to an index and the other end to a spindle. The deflecting force is measured by the angle through which the spindle must be turned in order to bring back the index to its original position. In a modification for use as a voltmeter, the low resistance coil and its prolongations are replaced by coils of high resistance. 1 claim.

7,773. "Improvements in electric signal apparatus for fire alarms, telephone calls, and for like uses." H. A. SAUNDERS and A. C. BROWN. Dated May 15th, 1884. Relates to that kind of electric signalling apparatus in which the pendulum of a transmitting instrument sets in motion the isochronous pendulum of a receiving instrument in the same circuit, and consists of improvements in the transmitting and receiving instruments. The transmitter consists of a conducting rod suspended by a flat spring and carrying a flat spring, to which is attached a pendulum with an adjustable bob. The conducting rod swings between adjustable contact stops and breaks the circuit once in each vibration of the pendulum. Another form of transmitter has an ordinary adjustable pendulum, to which is attached a spring contact arm, bearing on contact pieces so arranged that the circuit is made and broken several times in each swing. The receiver has a pendulum suspended by a spring or pivot, and with the lower part of the pendulum connected with the upper by a flat spring. An electro-magnet excited by currents from the transmitter acts on the upper part, and sets the pendulum in motion. The motion of the upper part of the pendulum is limited by the electro-magnet and the stop. Methods of using these instruments for fire alarms, telegraph, telephone, messenger and police calls, and railway trains, are described in the specification. 5 claims.

8,448. "An electric switch." E. F. H. H. LAUCKERT. Dated May 30th, 1884. Relates to electric switches and consists in adapting carbon rods so that the sparks which may occur on making and breaking contact may pass between the carbon rods instead of the metallic surfaces. The carbons are fixed to the other parts by springs, and are so arranged as to be the first to make and the last to break. 1 claim.

THE

ELECTRICAL REVIEW.

VOL. XLII. MAY 20, 1898. No. 1,069.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4, LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

THE ECONOMICAL EFFECT OF LIVE STEAM FEED HEATING.

IT seems to be accepted as an experimentally proved fact that the heating of feed water by live steam is productive of great economy. Several reasons are assigned for this. One is that the thermo-dynamic availability of the furnace heat transmitted to the water at a point nearer to the furnace temperature raises the efficiency of such heat. We look doubtfully on this explanation. Another reason is that the general circulation in the boiler is improved. If all the water in a boiler is at the full temperature of the steam space, as it would be if the feed were put in at that temperature, the application of further heat at any point would instantaneously cause steam to rise from that spot, and the water would nowhere be dull and sluggish, but would sweep freely over the plates and keep them cool. It is also offered as an explanation that when the boiler plates are hot there is less refraction of the heat passing through from the fire to the water side, and that it is possible we are all in error in thinking that heat transmission is the more rapid according as it traverses a medium interposed between bodies having the greatest difference of temperature. Light, we know, travels best in a homogeneous body. Is it not possible that heat also will travel better through a plate which has least difference of temperature in its own substance. In a paper by M. Normand, read at the 36th meeting of the Institute of Naval Architects, the author attributed an economy of 20 per cent. to his system of feed heating. He took the steam from the low-pressure cylinder of compound engines by a special valve, and his explanation of the economy was as follows:—

(*a*) An economy which results from the saving of so many thermal units due to using steam which has already done work in the cylinders. This saving may amount to 10 or even 14 per cent. (*b*) The circulation in the boiler is improved, and the plates kept better swept by the rapid passage of the water. He claims a trebled heat transmission from the same temperature difference. This latter economy would be that found where steam direct from the boiler is used to bring up the feed to a maximum, and it may be at the bottom of the better appreciation of the Lancashire boiler in the North, where economisers are used, than in the South, where they are comparatively rare, for it is very common practice to feed at maximum steam temperature from an economiser, leaving latent heat only to be supplied from the furnace.

In the absence of more data it is not possible to determine how the whole economy of feed heating is brought about. What is wanted are tests of a boiler with and without live steam heated feed water in order to determine two facts.

First, when using the steam are the waste gases reduced in temperature? This would show that the efficiency of heat transmission had been improved, and would prove that either the plates were more efficient, or had been more copiously watered by the more rapidly circulating water.

Secondly, does the use of steam cause any difference in the chemical composition of the waste furnace gases? It is possible that their temperature might be higher even with increased economy, for the higher temperature might be due to better combustion. If, therefore, with the colder feed an undue proportion of combustibles appeared in the waste gases, it might well be argued that this was due to contact with chilled plates. It has been shown experimentally that in contact with cold plates there is a stratum of unconsumed gas which cannot ignite, because of being cooled below ignition point. This implies waste. Mr. Thos. Fletcher, the manufacturer of gas apparatus, has shown that better results can be obtained with boiling vessels over gas flames when the bottom of the pot is studded with short projections, not so much that these afford a greater area, as that they get a little hotter than the water-cooled bottom, and do not extinguish flame. The combustible gases are thus enabled to complete their combustion. Until it is known by experimental determination how the use of live steam for feed heating affects the above conditions, the reasons for the economy which results must remain speculative.

The method of M. Normand of abstracting steam at mid-stroke from the low pressure cylinder, or in triple and quadruple expansion engines from the low pressure casing, seems well calculated to produce economy. Such removal will only slightly affect the mean pressure in the final cylinder, for it will doubtless reduce the back pressure, and if suitably arranged to abstract any collected water, may prevent some re-evaporation during the exhaust stroke, and serve to reduce the range of cylinder temperature, or the amount of its internal surface cooled by such re-evaporative effects. With every pound of steam so abstracted will be taken 966 heat units that would otherwise go to the condenser. In the compound engine, its abstraction at mid-stroke will be of very little moment on the score of power, while the less favourable point of abstraction in triple engines will matter little, because of the smaller relative value of the final cylinder.

In large boilers which are apt to contain a good deal of dead water in their lower parts—a fault that the water-tube and under-fired shell boilers do not possess—an injector or water propeller might be arranged to draw water from the bottom of the boiler and deliver it at the water surface, so as to draw down hot water to the boiler bottom. It was with this object that internally fired boilers were fitted with cross pipes in the tubes. These, however, defeat their object, and some positive means for circulation should be adopted in these boilers.

Professional Amenities.

THERE once was a time, within the memory of living man, when the announcement of any great scientific discovery was hailed with satisfaction throughout the civilised world, and the congratulations due to the man who had added to our knowledge was freely and cordially given by his co-workers in the domain of science, without any of the heart-burnings and petty jealousies which are so prevalent in these degenerate days. We have only to instance the recent achievement of Prof. Dewar as an example of the strained relations which now so frequently exist amongst scientific men. Prof. Dewar has been striving for years to liquefy hydrogen, and only a week or so ago he brought his labours to a completely successful issue. This wonder of modern chemistry is barely announced when a rival chemist, on the strength of a private letter from Cracow, combats Prof. Dewar's claims to priority and awards to Prof. Olszewski the distinction of being the first to liquefy hydrogen. This letter, said to have been written in 1895, Prof. Ramsay was challenged to produce, but apparently it was not forthcoming. This is all the more to be regretted, as it is apparently quite at variance with one of the latest publications of Olszewski, wherein he confesses his failure to accomplish what Prof. Dewar has succeeded in performing. Whatever doubt may exist as to the rival claims of the two great chemists should be set at rest by a letter in the *Pall Mall Gazette* of last Tuesday under the *nom de plume* of "One Who Knows," and the report on page 6 of Wednesday's *Times* of a paper read before the Paris Academy of Sciences on the 16th inst. This is not the first time we have felt it incumbent upon us to draw attention to the disparagement of Prof. Dewar's brilliant achievements which has been assiduously carried on in certain quarters for a considerable period, and it is now to be hoped that a better feeling may prevail in the divided ranks of the chemists, for it cannot be said that the controversy has been carried on in a manner which reflects much credit on one side at least. The peace on earth and goodwill towards men kind of spirit which seemed to prevail in Faraday's time appears to have lain dormant ever since, if it has not been wholly swept away in these days of high pressure and self-interest.

Lightning Arresters for High Tension Circuits.—The *Engineer* (New York) of April 1st prints a long illustrated article from Mr. Alexander J. Wurts on experiments with lightning arresters for high tension circuits. These arresters are intended to provide, at intervals along the distribution mains, spark gaps between the conductors of the system of low resistance in comparison with the rest of the circuit, and means for breaking the arc formed on the passage of a pilot spark from a lightning flash. They are, of course, quite different from telegraphic lightning arresters. The experiments were directed to testing the resistance of the gaps to sparking, and the rapidity with which the arc was broken after formation by a pilot spark. The discharge from a Leyden battery, excited by an electrical machine, was employed to produce the pilot spark. The resistance to sparking was measured by adjusting another gap in parallel with the arrester until the spark passed indifferently between them, and the spark was produced by shortening another gap in series with the two. The rapidity with which the arc was broken was indicated by the flicker on a bank of incandescent lamps arranged in parallel with the arrester. The occasion of the experiments and the article was to defend the author's (Wurts's) pattern of lightning arrester from the competition of another brought out under the name of Wirt's, and a third design was tested at the same time. The interest to us lies not in the commercial reputations of these arresters, but in the clear way in which the non-arcing quality of zinc alloys is brought out in the experiments, so that no arc can be maintained under an alternating pressure between such substances. The dimensions of the two parts between which, by a pilot spark, the discharge is started, seem to matter little, so long as they are made of a non-arcing alloy, and it appears that in no case where these materials are used does the discharge last beyond the time when, in the cycle of alternation, the current falls to zero. It is generally understood that alternating currents are more readily interrupted than direct currents, and the experiments, we gather, do not bear on the latter, arcs from which are generally dealt with by a magnetic blow out.

ELECTRIC LIGHTING AT WIMBLEDON.

It is now about 14 years since a series of experiments in street lighting by electricity was carried out at Wimbledon under the supervision of Mr. W. H. Preece; but, notwithstanding this early start, and the fact that a license was obtained as long ago as 1890, and a scheme prepared by Mr. Preece and Mr. Kapp, Wimbledon cannot yet be numbered amongst the towns which enjoy the benefit of an electric light supply. The local authorities do not, however, intend that this state of affairs should continue, and they have now obtained a provisional order, and have entered into contracts for the carrying out of a scheme prepared by Mr. A. H. Preece, and hope that, in the course of next year, they will be ready to supply current for public and private lighting. As the undertaking will be started under conditions which differ considerably from those which generally obtain, owing to the fact that 80 per cent. of the estimated output will be utilised for public lighting, we propose to give a few particulars of the scheme, for which we are indebted to the paper which was recently read by Mr. A. H. Preece before the Association of Municipal and County Engineers.

The streets of Wimbledon have for some years been lighted by oil lamps of about 20 candle-power each, of which there are at present about 800 in use. It is now proposed to use incandescent lamps of 32 candle-power, each oil lamp being replaced by one, or, in some of the more important thoroughfares, by two or more incandescent lamps; and for this street lighting about 900 lamps will be required. In addition to the public lighting, the scheme provides plant for the equivalent of 6,000 8-C.P. lamps for private lighting, and it is estimated that there will probably be 5,000 lamps connected in the course of the first 12 months' working. Owing to the large area to be covered, a high pressure alternating current system has been adopted, current being generated at 2,200 volts, and transmitted to transformers placed in underground chambers, whence it will be distributed by a three-wire system of mains with 400 volts across the outer conductors.

The generating plant will consist of three Crompton 120 kilowatt alternators and exciters direct coupled to Willans engines, for which a combined efficiency of 80 per cent. and a steam consumption of 28½ lbs. per kilowatt-hour have been guaranteed. Steam will be supplied by three Babcock and Wilcock boilers, each capable of evaporating 5,000 lbs. of water per hour; and to these is to be added a dust destructor plant, from which it is hoped to obtained sufficient steam to supply the requirements during the daytime, and perhaps after midnight, not only of the electricity works, but also of the adjacent pumping station. The high pressure mains will be concentric lead-covered cables, drawn into earthenware pipes, the outer of the concentric being earthed at the station. There will be three high pressure feeders terminating at distributing centres, which will also be interconnected by heavy mains, so as to allow of any feeder being thrown out of service without interrupting the supply. From these centres will branch out other and smaller high pressure mains or sub-feeders, which will transmit the current to the transformer stations, provision being made for separate sub-feeders and transformers for the public lighting, so that the street lamps can be switched on or off from the distributing centres without interfering with the private lighting. Although this arrangement will entail an extra expenditure on mains and transformers, great benefit should be derived from the concentration of all switching gear at the three distributing points, and from the greater efficiency of distribution, due to the fact that the transformers for public lighting will not be in circuit except when they are working at their normal full load output.

Provision will also be made for separate low pressure distributing mains for public and private lighting, the public lamps being arranged in circuits of from five to ten lamps each. Two different systems of laying these mains will be employed, according to the nature of the probable demand for private lighting, and to the class of pavement under which the mains are to be laid. When the demand for private lighting is uncertain, and the pavement is of such kind as to make it expensive to open up and make good, pipes will be laid down into which cables can be drawn as required; but when the demand for private lighting is certain, armoured cables will be laid direct in the ground; and the same plan will be followed under gravel pathways even when the demand for private lighting is so doubtful, then only public mains will be laid in the first instance.

As it will be necessary to lay mains in practically every street for the public lighting, the cost of mains, transformers, and public lamp connections forms an unusually large proportion of the total expenditure; this item being estimated to cost over £18,000 out of a total, including buildings and contingencies, of £32,000; whilst the estimated cost of the station plant is only £8,500, or less than half that of the distributing plant. The cost of this latter undoubtedly forms a very heavy charge, but it is stated that provision has to be made for about 40 miles of street, requiring 15 miles of high pressure and 50 miles of low pressure mains, besides some 20 miles of pipes. With regard to output and cost of production, Mr. Preece estimates that there will be an annual output of 300,000 units, of which about 80 per cent. will be required for the street lamps; and that owing to the regularity of the output due to the relative importance of the street lighting, the total cost of production will not exceed 2d. per unit, making £2,500, or a total expenditure, including interest and sinking fund, of £4,200 per annum. Owing to the profit to be derived from private lighting at 6d. per unit, it is estimated that the actual cost to the local authority of the 900 32-candle-power lamps will be only £2,450 per annum as against the present cost of £2,000 for the 800 oil lamps, or an increase of less than 25 per cent. for nearly double the amount of light; and that probably by the end of the second year the revenue from private lighting will have increased sufficiently to make the charge for the street lamps no more than it is at present.

THE ROYAL SOCIETY CONVERSAZIONE.

The usual exhibition of scientific novelties took place at Burlington House on Wednesday, 11th inst., when the first of the Royal Society's two annual conversaziones came off.

Among the scientific questions in the air at the present time, wireless telegraphy takes a first place. This was represented by a working installation of Lodge's system exhibited by Dr. Alex. Muirhead and Prof. Lodge. Telegraphic messages were being sent by this apparatus over the longest clear range obtainable in the Royal Society's rooms, for the electric waves, though they can penetrate through a moderate thickness of more solid substances, prefer, like the waves of light, to pass through air. Lodge's apparatus, of which a short description has already been given in the Electrical Review, Vol. 42, p. 103, consists of two fan-shaped sheets of copper connected at their apices by a coil consisting of a few turns of thick wire. The electric impulses are imparted to this system by sparks passing across air-gaps of about ¾ inch near the centres of the copper sheets. The sparks are obtained from an induction coil, the current of which is controlled by the punched ribbon of an automatic transmitting telegraph instrument. The receiver is exactly similar to the transmitter, but in this latter a coherer and syphon recorder are connected (in the same circuit) in shunt with the coil connecting the sheets of copper. The coherer used was of the very simple form first devised by Prof. Lodge, in which the end of a flat steel spring is pressed against an adjustable steel point—a kind of microphone sensitive to electric instead of sound waves. The telephone may be used as a receiver instead of the siphon recorder, in which case no tapper is required for the coherer, and a much higher speed of telegraphy is possible. The greatest distance over which Prof. Lodge has telegraphed with his apparatus is about 1 mile, and at that distance no falling off in its action was observable.

For wireless telegraphy at very long distances, however, Lodge prefers his system of "magnetic space telegraphy." The apparatus for this system was shown in the secretario room downstairs. The system depends on the mutual magnetic induction of two coils placed at distant points on the earth's surface. The discharge of a condenser or Leyden round a large wire coil sets up an alternating magnetic field, which excites induced currents in another distant condenser circuit tuned to the same frequency, causing the second

Leyden either to overflow into a coherer, or to disturb a Rutherford detector or a telephone, so as to give a signal. The detector shown was a special series of small free coils and granular microphones, each coil in a permanent magnetic field, and so connected to the microphone of the next, that a very feeble alternating current in the first of the series is able to make a telephone in the last emit a loud sound, or through a Langdon-Davies relay, to ring an electric bell and work a Morse sounder. A tone-telephone was also shown, which acted as a highly syntonised call. This highly sensitive receiver for magnetic oscillations had an extraordinary peculiarity, which Dr. Lodge described as "talking to itself." When two of its coils were placed relatively to each other, so that their mutual induction was large, the one starts automatically to act on the other, and the telephone begins to sound.

Mr. Mackenzie Davidson exhibited his apparatus for finding the true position of foreign bodies in objects photographed by the Röntgen rays. This has already been described in the ELECTRICAL REVIEW. He also exhibited a Wheatstone reflecting stereoscope for looking at Röntgen photographs.

Mr. A. A. Campbell Swinton had a very interesting exhibit illustrating his recent discoveries in the discharge in vacuum tubes. Radiometer mill wheels were employed to detect the direction and velocity of the gaseous streams, and the experiments indicated that in very highly-exhausted tubes of the focus type, in addition to the well known negative stream from the cathode, discovered by Crookes, there existed also a positively electrified stream from the anode, which travelled in the opposite direction to the cathode stream and exterior to the latter. A pinhole Röntgen ray camera was also exhibited by Mr. Swinton, with which he had taken photographs of the active area on the anti-cathode, which corresponded with the results he had already obtained on cathode discs. Lastly, though not least interesting, were Mr. Swinton's cathode ray lamps. Two concave cathode discs focus on a cube of refractory material, and give out sufficient light to illuminate a small room. The efficiency of this method of producing light is considered to be quite equal if not greater than that of the arc light.

Mr. Killingworth Hedges exhibited specimens of copper deposited by a process invented by Mr. J. C. Graham. Mr. Graham by mechanical means causes a circulation of the electrolyte over the surface of the cathode. By this device he claims that he can use 10 times the density of current hitherto employed, and yet obtain a more homogeneous deposit.

Prof. Ewing exhibited his new magnetic balance for permeability tests of iron. This apparatus has been designed to afford an easy means of judging of the magnetic quality of iron or steel with special reference to its suitability for use in dynamo magnets. The specimen to be tested is in the form of a turned rod, which lies across the poles of an electro-magnet excited by a constant current. One side of the rod touches both poles, and the force required to pull it away from one pole is measured, the contact with the other pole serving as a hinge. The force is measured by means of a weight which slides along a graduated scale-beam, and the beam is graduated to give, by direct reading, the value of the magnetic induction, B, which would be produced in the tested samples by a constant magnetising force, H. The constant magnetising force selected for the purpose of the test is 20 C.G.S. units, that being a sufficiently strong force to exhibit the quality of different specimens in respect of permeability under strong magnetisation.

Prof. Callendar exhibited electrical recording apparatus. This apparatus is capable of recording almost any kind of electrical quantity directly, and can be made to record other quantities indirectly, as, for instance, temperature by means of the variation of electrical resistance. It has been in use for more than a year at McGill College, Montreal. A brief mention of the apparatus, with illustrations of some of the results obtained, was communicated to the Royal Society of Canada at their last year's meeting in June, 1897, and has been published in their *Transactions*. The principle upon which the apparatus works is extremely simple. A pen or planimeter is attached to the contact point on a "slide-wire," and is kept automatically at the balance point by means of a delicate relay, controlling a pair of clock motors. The co-ordinates of the record are consequently rectangular, and the scale is one of equal parts in the majority of cases. The following are some of the special cases to which the apparatus has been applied:—Electrical records; resistance, voltage, current, and power; temperature records by thermo-couple, or by platinum thermometer; records of sunshine and humidity; cycle records; steam temperature cycles in the cylinder of a working steam engine; forms of alternating current and potential waves.

Mr. C. Orme Bastian exhibited an electric current meter acting by electrolysis, the ampere-hours being measured by the decrease of a column of the electrolyte (dilute H_2SO_4).

Mr. Wimshurst exhibited a Röntgen tube-holder, designed to prevent leakage in the leads, and showed experiments, in which the direction of the electrical discharge was indicated by small fans.

AN AUTOMATIC TELEPHONE EXCHANGE.

MANY and varied attempts have been made to evolve a system of reliably effecting inter-communication between the circuits of a number of telephone subscribers concentrated at one central point or exchange without the aid of an operator at that place. The problem presents difficulties which have not hitherto been successfully overcome, but a system recently developed, and now being exhibited by the

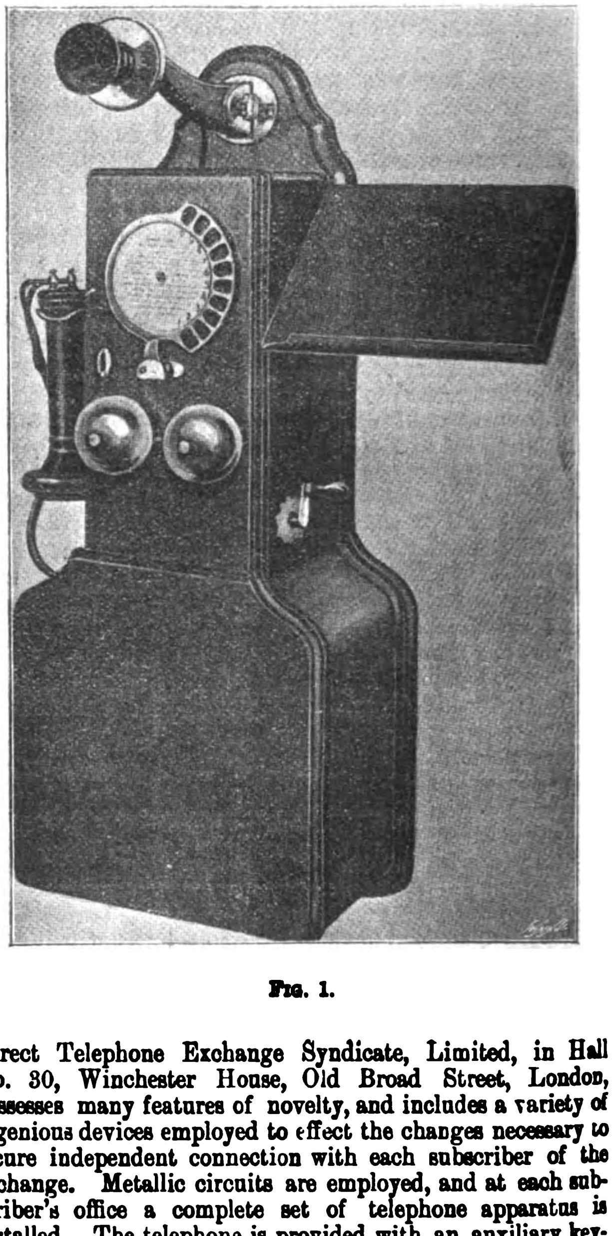


FIG. 1.

Direct Telephone Exchange Syndicate, Limited, in Hall No. 30, Winchester House, Old Broad Street, London, possesses many features of novelty, and includes a variety of ingenious devices employed to effect the changes necessary to secure independent connection with each subscriber of the exchange. Metallic circuits are employed, and at each subscriber's office a complete set of telephone apparatus is installed. The telephone is provided with an auxiliary keyboard or commutator, by the use of which the sequence of the currents necessary to actuate the automatic switching apparatus at the exchange is determined. The subscriber's instrument is illustrated by fig. 1.

The keyboard, shown on the upper part of the apparatus, is disc-shaped, and revolves around its centre, whence it is connected by means of an axle to the commutator internal to the instrument. The commutator is constructed on the well-known principle usually employed in municipal and other messenger and police call systems, where the operating of the call key winds up a clockwork system, which, during the act of running down, rotates a star or toothed wheel, which determines the number of current impulses generated for each movement of the keyboard. As a preliminary to ringing a correspondent in the usual way, the subscriber originating the call must effect the connection at the exchange between his circuit and that of his correspondent by operating the keyboard of his apparatus. This is effected by inserting the tip of the finger into a hole in the keyboard (seen in the figure) corresponding to the number required, and pulling the keyboard round to the stop, where, on being released, it returns to zero automatically. This operation is repeated for each figure contained in a concrete number representing the subscriber wanted, who is subsequently rung by the magneto-generator in the usual way.

At the exchange each subscriber's circuit terminates on an electro-magnetic switch, illustrated by figs. 2 and 3, which

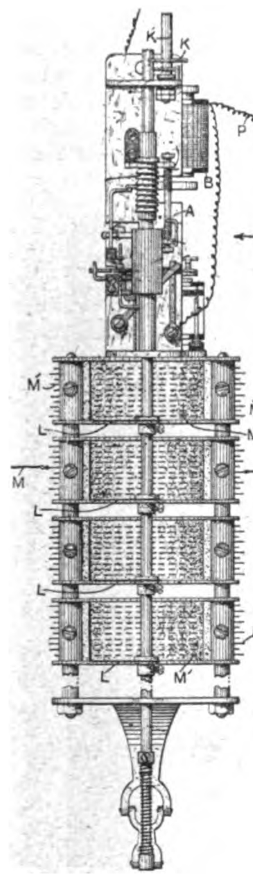

Fig. 2.

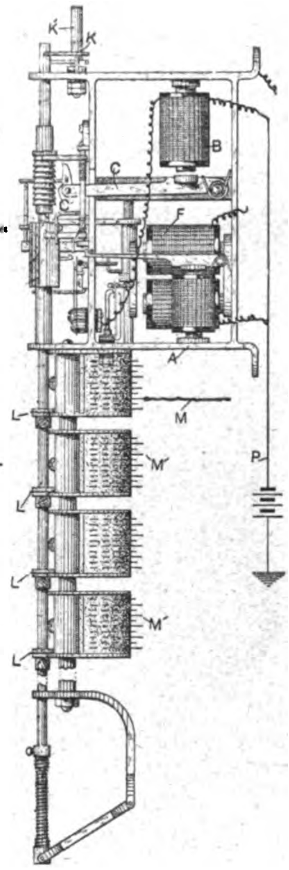

Fig. 3.

are a front and side elevation respectively, and where D is a rod movable vertically and circularly. The rod D carries a series of flexible contact arms L which effect connection with the metallic segments of the semi-circular distributors, M′; B is an electro-magnet, the lever C of which raises the rod D to the proper height for bringing the contact arms L into line with the row of segments with which connection is required on the distributors M′. These segments correspond with the multiple jacks of subscribers' circuits connected to ordinary manual boards. F is the motor magnet by whose armature lever the rod D and consequently the contact arms L, are rotated into connection with their proper segments upon the distributors, each segment of which is connected by a cross connecting wire, shown at M, with the corresponding segment of each switch throughout the exchange.

One wire of the metallic circuit may be considered as terminating upon the rod D, whence connection is continued to the segments of the distributors of the other switches, as described above, by means of the stud K′, with which a projecting pin, K, on the upper end of D makes contact when the apparatus is at rest in the normal position. The other wire of the circuit is terminated upon an insulated flexible steel spring normally disconnected. When therefore, the rod D is rotated, the pin K is moved away laterally from the stud K′, and the segments on the other switches to which this stud is multipled are thus isolated from the subscriber's circuit for the time being. The electro-magnetic switch connected with the circuit of the subscriber who is called is not, however, actuated, and provision has therefore to be made to prevent other subscribers obtaining access to his circuit whilst it is in possession of the correspondent who first called. This is effected by the auxiliary electro-magnet A, brought into use through the medium of a local circuit, and whose armature lever when depressed disconnects the circuit of the contact arms L on the switch of the third subscriber, by which means privacy is secured to the two subscribers who are already in communication. The bottom group of segments on each switch is reserved for connecting up these "non-interfering" local circuits.

A subscriber requiring to communicate with another whose circuit is already engaged, ascertains that he has failed to secure connection by his bell remaining silent when he operates his magneto-generator to call his correspondent. A separate segment is set apart in each subscriber's automatic

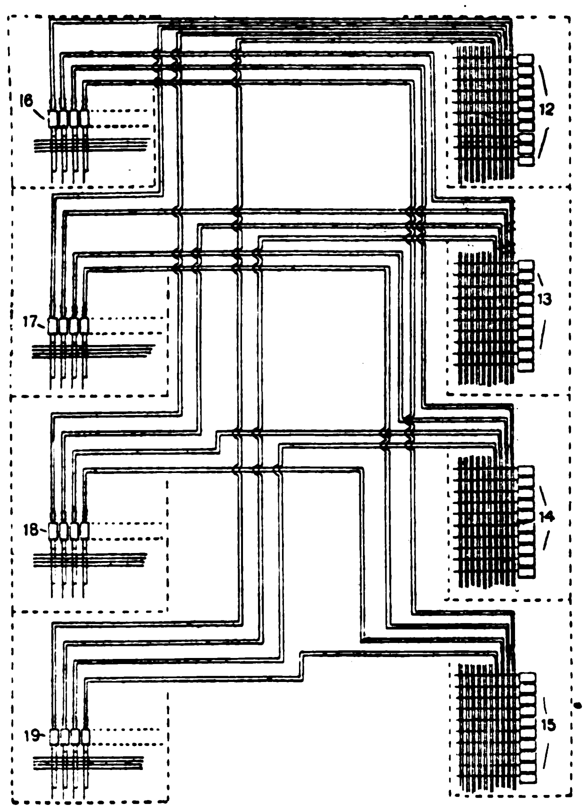

Fig. 4.

switch, to which he may connect his circuit by calling a prearranged number, and speak to the office of the manager of the system if he has reason to suspect that his apparatus is out of order and desires to verify it.

The battery P, which energises the electro-magnets of the switches is located at the exchange, one battery being common to the entire exchange.

To safeguard the apparatus from damage by stray currents from adjacent power circuits with which the telephone wire may get into contact, a "time fuse" is inserted in the wire of each subscriber's circuit connected to the motor magnet. This fuse is shown by fig. 5, where W is a solenoid of wire enclosing an ebonite core, and S S′ are flexible springs. The heating effect upon the wire W, of a continuous current, exceeding the current of half an ampere, with which the apparatus is actuated, causes the ebonite core C to expand and raise the spring S, when S′ being thus released, flies forward and breaks the circuit of the subscriber, simultaneously closing the circuit of a local alarm bell in the exchange, which gives warning of the fault. A similar result follows if the subscriber's wire finds accidental earth outside the exchange, when the motor battery P would be discharging continuously. A ready means is provided of locating an open time fuse upon the switchboard.

The act of hanging up the receiver at the subscriber's office after a conversation has terminated, causes a momentary

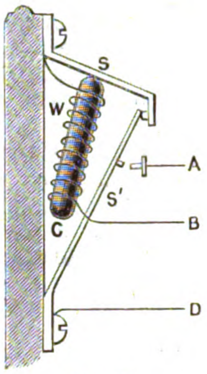

FIG. 5.

current to be sent through the intermediary of the switch arm of the telephone, and this current automatically restores the electro-magnetic switch at the exchange to its normal position.

The switch described is capable of providing for exchanges having a capacity up to 400 subscribers, above which number method of effecting combinations of numbers enables 1,000 subscribers to be reached; and by an extension of the principle it is claimed that 10,000 may be accommodated in one exchange.

In the apparatus described the electro-magnets actuating the switches are included in the circuit when conversation is going on, and are consequently given a low ohmic resistance, but in the latest development of the apparatus the "bridging" method of connection is introduced. The system has been in operation about four years, and is employed at some 20 exchanges in various States in America, some of which exchanges are built to a capacity of 1,000 subscribers. It is also in process of installation in a like number of cases at other places, at some of which a capacity up to 5,000 is being provided for.

A view of an exchange equipped to a capacity of 200 subscribers now in operation at Trinidad, Colorado, is shown by fig. 6. Each electro-magnetic switch occupies a lineal space of 12 inches × 4 inches, and projects 6 inches from the supporting base.

It will be gathered from the description that the automatic switch depends primarily upon its mechanical qualities for performing its functions. An exchange equipped with the apparatus must therefore be under the charge of a competent mechanician possessing electrical knowledge, and the accuracy with which the apparatus operates will depend upon the degree of skill with which its necessarily complex mechanism is maintained.

Apart from the central office system, there is a large undeveloped telephonic field within the residential suburban areas of our cities and towns, to the opening up of which the attention of inventors of automatic exchange apparatus has been directed, and where the provision of a reliable and con-

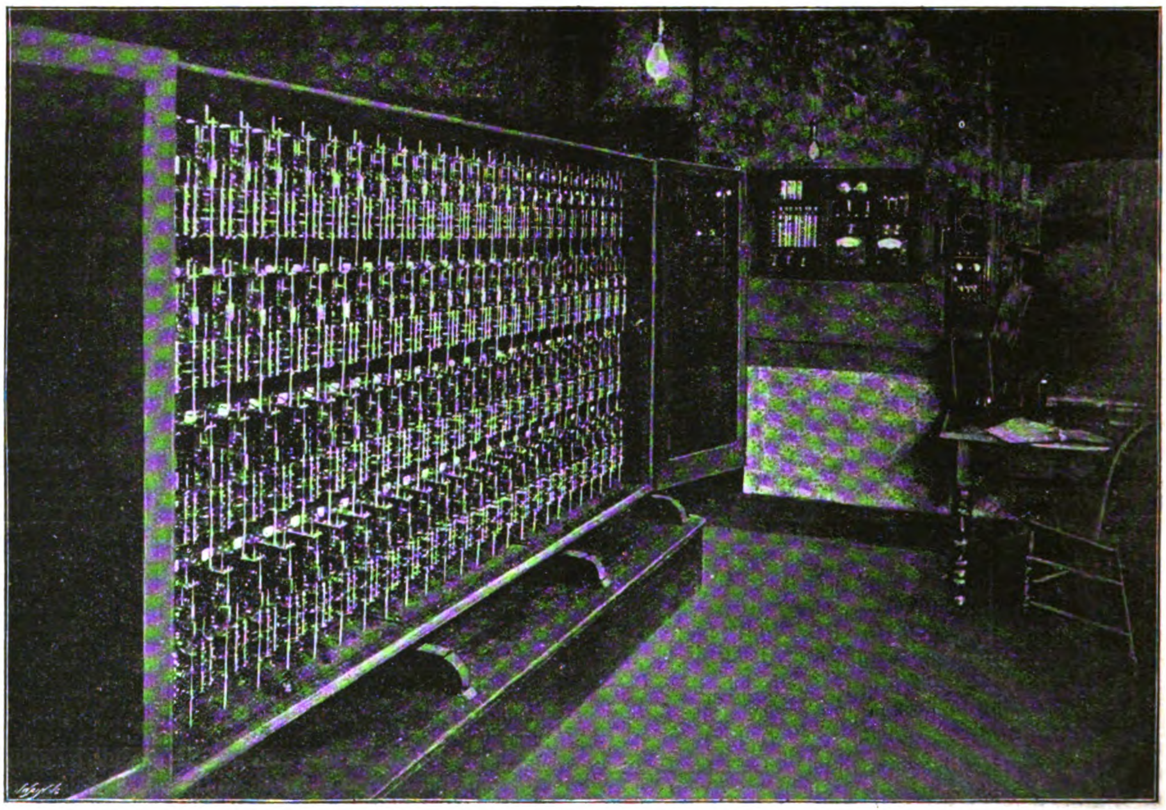

FIG. 6.

the combinations of numbers are obtained by allotting two switches to each subscriber's circuit, the first of which selects the groups of hundreds, whilst the second picks out the tens and units in each particular hundred. The principle upon which this sub-division is effected may be understood from fig. 4, where the switches diagramatically represented at 16, 17, 18, and 19 correspond with the first of a pair allotted to select the hundreds, whence the connections continue to the second switch of the pair where the sub-division to the tens and units of the different groups of hundreds is effected. The points of sub-division to the tens and units of the different hundreds are indicated at 12, 13, 14, and 15. This

tinuous automatic local service with tradesmen and others, giving optional access to the main system would appear to obtain an opening for employment.

The time occupied in operating the automatic exchange is virtually constant for any given combination of figures, and the subscribers are thus relieved by such a system from anxiety regarding preferential treatment by the operators, about which so much has lately been heard, but it is an open question whether, even in its improved state as now exhibited, the automatic switch will prove an efficient substitute for the manual operator, notwithstanding the ingenuity which has been exercised in working out its details.

LITTLE'S CONTINUOUS INTEGRATING STEAM INDICATOR.

There has been, we believe, up to the present time no instrument in existence capable of attachment to steam engines, which will automatically produce a record of the power developed during any desired length of run, and which will act in sympathy with any changes either of speed or steam pressure in the cylinder which the load on the crank shaft may demand. With the consent of the proprietors of our contemporary, *Engineering*, we reproduce an engraving of a new type of steam indicator, a full description of the theory and practice of which appeared in the issue of that journal of December 10th last, and this being so we do not propose to give more than a general outline of the aim and construction of this ingenious and handy instrument.

It will be seen from the woodcut that the general appearance of this indicator is similar to that of an indicator constructed to take diagrams as regards the steam cylinder and the drum, but that the pencil arm and parallel motion will be noted from the woodcut that the wheel stands normally at a certain deflection from the vertical, viz., about 85°, the object of which is to secure an accurate action between the contact surfaces and which is quite effectual, as will be seen from the subjoined trials of the instrument at the works of Messrs. Willans & Robinson, Rugby, on an engine of their usual type running at 350 revolutions per minute. It should be explained that although this permanent amount of deflection increases the amount of the record on the dial on the forward stroke by an amount proportional to the permanent initial inclination, the same amount of record due to the same cause is deducted by the return stroke, the difference being the actual amount of rotation of the wheel, which, owing to the mathematical conditions governing the instrument, is precisely proportional to the amount of steam pressure on the piston of the indicator during one revolution of the engine. There is, of course, no slip between the contact surfaces other than that due to the amount of inclination from the horizontal. The action of this indicator is, therefore, briefly that of a planimeter recording the areas of diagrams at every revolution of the engine, which a card

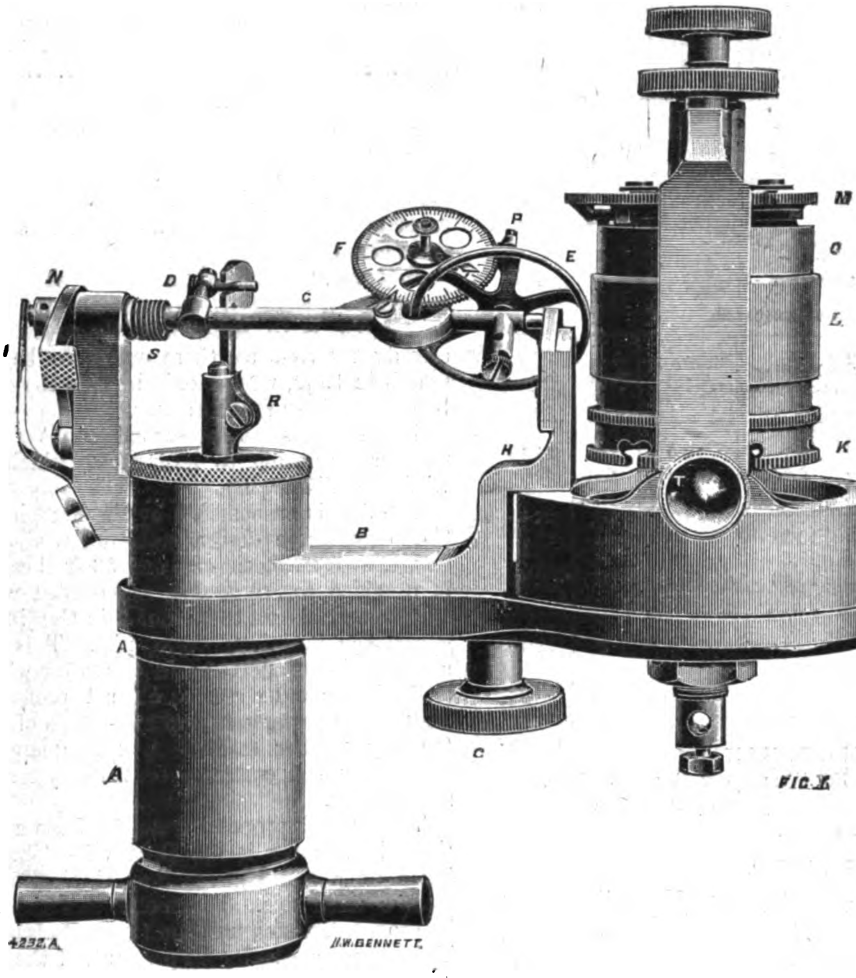

Fig. I.

are replaced by a device similar to the integrating mechanism of a planimeter, the wheel of which can be placed at will in contact with the drum in order to produce the desired rotary effect upon the wheel resulting from the combined action of steam pressure and piston speed, the requisite inclinations of the wheel being imparted to it by a simple sine motion of pin and slot as shown at D.

Since, therefore, the varying pressure of steam in the cylinder is made to produce the same amount of inclination of the wheel, as would be produced by tracing the actual diagram with the tracing point of a planimeter, it only remains to rotate the wheel by reciprocating the drum in contact with it, in order to produce the same result as if the drum (*i.e.*, indicator card), were held fixed and the diagram traced round with the point of the planimeter in the ordinary way. The amount of reciprocation of the drum (*i.e.*, length of diagram), is accurately measured to the second place of decimals by means of a simple device, M, actuated by the drum itself and which is quite easy of manipulation. It indicator would produce having the same piston area, the same piston spring, and a ratio of pencil movement to that of piston of six to one, the amount of reciprocation of drum being, of course, arranged to be the same for each.

For the calculation of H.P. by means of this instrument, the average area record per minute reduced to unit length by dividing by the amount of drum stroke if more or less than one inch was employed, is multiplied by a single figure composed of engine constants, &c., the result being the average H.P. per minute developed during the time the instrument was running. And for M.E.P. the unit area record per minute is divided by the revolutions per minute, which, in this case only, require to be known.

In cases, therefore, where a study of the steam distribution in the cylinder is not the object in view, but the actual efficiency of the engine, a knowledge of the latter can be much more accurately ascertained with the continuous indicator than by taking diagrams, and much labour in measuring them up is obviated, as also the necessity for counting revolutions. Moreover, where rapid changes of load are the rule, an accurate indication of H.P. is an impossibility with the ordinary indicator.

In electric light and traction installations it would seem that this form of power-meter should obtain for itself a wide sphere of application, as indications may be taken with it during a whole day or night, or at regular fixed intervals of working; no attention to it being required, unless it may be desired to take readings during the run, which is readily done even at high speeds, as shown in the table below:—

HIGH SPEED.

Test of Little's continuous indicator, made at the works of Messrs. Willans and Robinson, Ltd., Rugby, December 22nd, 1897, on a steady load, indications being taken simultaneously by a Crosby indicator. The two instruments were attached to the low-pressure cylinder of a large engine, running at 350 revolutions. The load was an electric one, and was kept constant by maintaining constant watts by means of an amperemeter and voltmeter in circuit.

ELECTRIC TRACTION PROJECTS FOR THE 1900 PARIS EXHIBITION.

AT the last Paris Exhibition it will be remembered that the little Decauville light railway in the Exhibition grounds, proved not only a great convenience to visitors, but what is of quite as much consequence, it was entirely a success from a financial standpoint.

No less than 6,000,000 passengers were carried on this little pleasure line, whilst the receipts amounted to a sum of £70,000. This success might naturally have been expected when we consider that the line was inexpensively built for a summer's traffic under very favourable circumstances—the expenses stopping as soon as the receipts grew less, and the line not continuing for the winter, when sparse traffic (or none at all) prevents profits being earned.

The people of Paris are evidently much inclined to favour light lines of this kind, as anyone will believe on seeing the little horse cars running through the top of the Bois de Boulogne into the Jardin d'Acclimatation; and we are rather surprised that no serious efforts have yet been made to run these cars by electricity.

However, there is no hesitation being shown with regard to electric traction schemes for the approaching exhibition, and if one is to judge from the successful Decauville line already referred to, there ought to be a most profitable season in 1900, were it only because the extent of ground to be covered is so much greater.

The schemes at present brought forward are five in number (according to information which we abstract from *L'Energie Electrique*).

The first is propounded by the French Thomson-Houston Company, whose design embodies a single track of metre gauge, with 22 motor cars and 33 trail cars. One class only is provided for, somewhat in contrast with the usual first and second classes to be found in Continental tramcars, &c.—and the fare is uniform, 2½d. This company asks for a subvention of £60,000, in return for which the Exhibition authorities are to receive all net profits on carrying up to 15,000,000 passengers, and two-thirds of subsequent profits for any further traffic. A cash guarantee of £4,000 is offered by the company that its system shall be worked successfully.

The second proposal emanates from a syndicate of which the chief member is the Decauville Company. This also is based on a metre gauge line, single track, taking current from a third rail. Ten motor cars and 40 trail cars would be provided, with a uniform fare and class as in the last case. The company asks for 55 per cent. of the gross receipts after £72,000 has been taken.

The third scheme is put forward by Mons. Leon Francq, acting in conjunction with the Fives-Lille Company. This proposal embraces a double track of normal gauge, with three-car trains having each a seating capacity of from 180 to 200 passengers. Twenty motor cars and 40 trail cars would be provided—all one class and one fare, 3d.—but special reserved seats at 5d. might be arranged for. Mons. Francq estimates the capital outlay upon his plans, if carried out, at about £140,000, and any receipts over and above such a sum would fall to the exhibition authorities. No payment, however, would be made except on the carrying of more than 15,000,000 passengers. From this number to 20,000,000 the concessionaire would pay one centime on each ticket, and similarly two centimes should the numbers range between 20,000,000 and 25,000,000; three centimes from 25,000,000 to 30,000,000; and five centimes or one half-penny per ticket for all over that number. Evidently Mons. Francq is ambitious and thinks that increased capacity for traffic will ensure the traffic coming into existence.

The fourth system is due to one of the Paris electric lighting companies, which proposes a single track of metre gauge built generally on the Decauville principle, and employing 10 motor cars with 40 trailers. Two classes would be provided with corresponding fares of 5d. and 2½d. This concessionaire offers 20 per cent. of the gross receipts, and 25 per cent. of the net receipts after allowing for depreciation and 5 per cent. upon the expenses of erection and exploitation.

The last proposal—brought forward by Mons. de Mocomble—is supported by Mons. Henri Maréchal (the well-known Paris engineer) and the Compagnie Générale de Traction. It comprises practically two separate schemes, one an electric railway and the other a two-speed moving sidewalk somewhat after the fashion of those already suggested, or actually built, for Exhibition purposes, as at Chicago, &c. The railway is designed on the metre gauge, is single track, and provided with eight trains in service (three in reserve). Each train would have a seating capacity for 250 passengers, and would be operated by motors having an output of 140 H.P. A central rail would serve as current distributor.

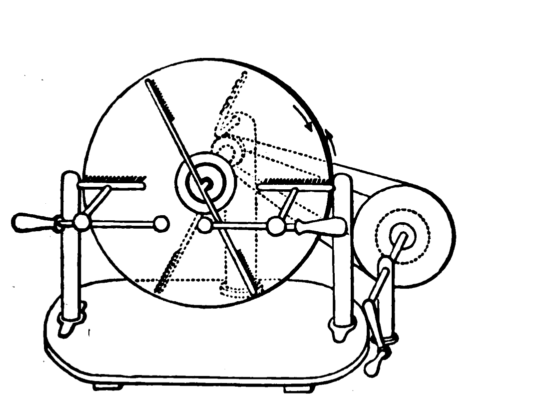
The "moving sidewalk" would run the opposite way round to the railway (it should, of course, be understood that all these proposals are for circular lines embracing practically the entire area of the Exhibition), and is built throughout on a viaduct after the fashion of the American elevated railways. It comprises a fixed platform approximately 3 feet wide, and two separate moving platforms, of which the first is about 2 feet 8 inches wide, running on a track of 18-inch gauge and maintaining a speed of about 3 miles per hour, whilst the second one has a width of about 5 feet 6 inches, with a track gauge of 3 feet, and runs at a speed of from 5½ to 6 miles an hour.

Our contemporary gives a very complete and interesting description of the working details of this moving sidewalk, and if the plans are adopted we shall hope to deal fully with the matter. At present it is sufficient to note that the power required to operate the combined arrangement is estimated to be about 472 H.P., and that nearly 40,000 passengers *per hour* can be dealt with.

HONOUR TO WHOM HONOUR IS DUE.

We read in a daily paper that Mr. James Wimshurst, inventor of the famous electrical influence machine, is one of the 15 men of science nominated by the Council of the Royal Society for election this year.

"The famous electrical influence machine" with which Mr. Wimshurst's name is associated was first described in *Engineering*, January 5th, 1883. On February 2nd in the same year a letter appeared in *Engineering* from Prof. Holtz, stating that the machine invented by Mr. Wimshurst had been invented by him (Holtz) in 1869. In one of the places cited by Holtz (*Pog. Ann.*, 136, p. 172), an influence machine is described, with an illustration, of which we subjoin a copy.



It will be seen from this figure that the machine consists of two glass discs driven by pulleys and belting in opposite directions. A neutralising rod with points for drawing off the electricity from the surface of the plate is set at a suitable angle opposite each disc. Collecting combs are placed in a horizontal diameter opposite the front disc.

Those who are acquainted with the Wimshurst machine will perceive that the only difference between it and the Holtz machine is in a few insignificant matters of detail. In the Wimshurst machine a number of radial strips of tinfoil are pasted on the surface of the discs. This makes the machine self-exciting. But Holtz pointed out in 1881 (Uppenborn's "Jour. of Prac. Elect." p. 199), that his machine could be made self-exciting by pasting tinfoil sectors on the face of the discs. He, however, considered that as the self-excitement could be obtained only at the price of loss of output, the tinfoil sectors were not to be recommended. Since Mr. Wimshurst's machine came before the public, more than one inventor has flattered himself that he has improved it by removing the tinfoil sectors. These ingenious inventors, unknowingly, no doubt, merely reverted to the original form of the machine as brought out by Holtz in 1869.

The second point of difference between the Wimshurst and the Holtz machine is in the collecting combs. In the Wimshurst machine the collecting combs are double, that is to say, there is one opposite the face of each disc. Now, Holtz states that he has tried the double collecting comb, and has found that it is not so good as the single comb.

Holtz may be wrong in both these matters of detail, but nobody could consider that it affects the principle of the invention one way or the other.

Mr. Wimshurst may have other claims to be elected a fellow of our leading scientific society, but it cannot be said that he has been elected because he is the first "inventor of the famous electrical influence machine." The scientific man often gets nothing for his discoveries except the honour of being the first discoverer, so there is all the more reason why the scientific public should see that honour is given where honour is due.

A NEW INTEGRATING MACHINE.

In another column will be found a description of Mr. W. G. Little's integrating steam engine indicator. This beautiful instrument is the latest addition to an interesting class of apparatus which has received much attention from mathematicians and mechanics in recent years. We suppose there are no problems of such entrancing interest as the construction of integrating machines to both the geometrician and the mechanic, while they exceed almost all other geometrical problems in immediate application to practical problems of surveying and engineering. The term integrator, in its widest sense, includes all the clocks which integrate time, the automatic coal weighing machines which integrate mass, the gas and water meters which integrate volume, the electrical motor meters which integrate the product of force and time, the chemical meters which integrate mass or volume according as they act by the weight of metal deposited or the volume of gas generated, as well as this indicator of Mr. Little's, which integrates the product of force and distance, *i.e.*, work. Integrators were in use when Alfred put candles in lanterns, and when Galileo and Huyghens applied the pendulum to clocks. Calculating machines, such as Babbage's and the Brunsviga, curve tracers, and tide predictors are not integrators, though they perform mathematical operations of an allied kind. The integrating machines which have occupied so much of the attention of mathematicians during the last 30 years, and perform such curiously complex operations, are all machines for calculating the properties of plane or developable curves, closed or periodic. The initial impulse was given to these designs by the invention of Prof. Amsler's well-known planimeter, largely used now for measuring areas on maps and engineer's drawings, and more commonly still on indicator cards. The use of a similar instrument for obtaining the volumes and moments of inertia of solid figures swept out by the rotation of closed curves about an axis is less generally known, but it suggests as possible an almost indefinite extension of the principle to other problems; the principle, *i.e.*, of counting the revolutions of a wheel rolled over a surface, the speed at which the wheel revolves depending on its movement over the surface, and the angle between its plane, and the direction of its motion. All the integrating machines that we know of, produced since that time, depend either on this principle of Amsler's, or on moving the wheel along a revolving cone. The latter plan is less elegant, geometrically speaking, and less elastic in its applications, but it has been useful in some cases. We may recall its employment in Siemens's steel wire slack percentage indicator, and within the last few months has been described a singularly complicated and inelegant application of it to a recording and integrating electrical instrument by Richard Fréres, in which the cone has its extreme form of a disc. But of integrating machines working on the same principle of Amsler's in some form a great variety have been proposed. In South Kensington Museum there are several models of rolling wheel and cylinder integrators designed by Mr. Vernon Boys. A very ingenious planimeter using a Peaucellier cell is due to Prof. Hele Shaw. The ergometer, or integrating transmission dynamometer of the Rev. F. Jarvis-Smith is probably the most perfect instrument of its kind yet designed, and Prof. Henrici's harmonic analyser made by Conradi, of Zurich, is a real triumph of mechanical design and construction. The list could be increased almost indefinitely. All these instruments, depending on the perfect rolling together of two bodies, suffer more or less from slip, and the error is apt to increase with the speed of the operation, and with the angle between the directions of motion of the two bodies at the contact point. Prof. Unwin's first letter to Mr. Little mentions his apprehension that the error due to this cause in the readings of the indicator might prove serious, but it seems clear that good workmanship and design have reduced the error to a very small amount, and it is probable that the indications of Mr. Little's instrument are at least as trustworthy as the figures obtained from a series of cards. The design would not have appeared to us to promise great accuracy; we should have looked rather to an instrument on the lines of the ergometer; but Mr. Little's figures are unexceptionable, and he has, without doubt, produced an extremely valuable instrument. It is unnecessary to point out the convenience of using such an indicator in prolonged steam trials, though it is probable that cards would be taken at intervals in addition as a check. We have no doubt that the instrument will be found in all laboratories and engine-testing rooms, and that its use will suggest to engineers other useful applications of integrating apparatus.

CORRESPONDENCE.

Electrolytic Refining of Lead.

I have just read the article on the electrolytic refining of lead that Mr. Sherard Cowper-Coles has published in the Electrical Review for April 22nd last.

As this article contains some criticisms relating to my process of electrolytic desilverisation of lead, I ask you to permit me to say a few words in answer thereto.

Firstly, in the numerous experiments that I have had occasion to make on different kinds of lead, I have never observed any deposit of peroxide of lead (Pb O_2), nor any other oxide on the anodes.

Secondly, the composition of the bath does not vary, for the acetic acid is not at all decomposed; and, in fact, during the passage of the current through the baths I have never detected the smallest escape of gas.

Here, then, are the well-established facts that everyone can test, and which are, however, in contradiction to the observations (which are, by the bye, very polite) that Mr. Sherard Cowper-Coles has addressed to me on the subject of my process of electrolytic desilverisation of argentiferous lead.

D. Tommasi.

Knots.

Some interesting correspondence on the subject of the *knot* has recently appeared in your journal. The term "knots per hour" has long been an abomination to many of us when used in the sense of "miles per hour." The excellently put protest against the use of "*knot*" for "nautical mile," which opened the correspondence alluded to, has been, I am confident, widely appreciated. I write to call your attention to analogies which ought to suffice to fix the meaning of *knot* to give it the meaning of "one nautical mile per hour." One analogy is the ampere, which expresses a rate of flow of electricity; another, is the watt, which expresses a rate of production or consumption of energy. Add to these the knot, expressing a rate of speed, the miner's inch, expressing a rate of flow of water, and a few others, horse-power, &c., and we have a group of practical units, whose analogy is interesting and instructive in, at least, one case, the ampere. Then just as a current of 10 amperes indicates a flow of 10 coulombs per second, so does a speed of 10 knots indicate a speed of 10 nautical miles per hour. But the ampere is not a coulomb, and the knot should never be treated as a nautical mile. A slight struggle against this misuse of the knot may be traced in our dictionaries—it is to be hoped that the misuse may vanish. But when we remember how many years were required to educate professional electricians out of the expression "one-hundred volt current," or "thousand volt current," we must not be too hopeful.

T. O'Conor Sloane.

New York, *May 7th.*

LEGAL.

Cooper v. The Electrical Installation Company and Another.

Rights of a Patentee under an Assignment.

Before the Court of Appeal, composed of Lords Justices A. L. Smith, Chitty, and Vaughan Williams, on Saturday, May 14th, the case of Cooper v. Electrical Installation Company, Limited, and another, came on for hearing. This was an appeal by the plaintiff from an order by Mr. Justice Darling in Chambers, in the Queen's Bench Division. Mr. E. W. Sinclair Cox was counsel for the appellant, and Mr. George Wallace for the respondents.

Mr. Sinclair Cox said the defendants in the action consisted of two companies, the Electrical Installation Company, Limited, and the O'Brien-Lennard Electrical Installation Company, Limited, and the order appealed from was an order striking out plaintiff's statement of claim in so far as it affected the O'Brien Company, on the ground that as against the O'Brien Company it disclosed no reasonable cause of action. The plaintiff, Mr. Henry Hayes Cooper, was the inventor of an electrical safety wall plug, and the patent was originally in the names of Cooper and the Electrical Installation Company. By agreement of July 19th, 1894, plaintiff assigned to the Electrical Installation Company his moiety of the patent.

Mr. Wallace: They were joint patentees in the first instance.

Mr. Sinclair Cox said that Cooper and the Electrical Installation Company entered into covenants under the agreement, for themselves and their respective representatives and assigns, by which the company was to pay to assignor Cooper royalties half-yearly in respect to each article manufactured under the patent by them or their licensees, to pay all stamp duties and fees for keeping up the patent, and to do all in their power to promote the manufacture and sale of articles manufactured under the patent, and the use of the invention in every possible way, and not to manufacture or apply any other invention which might supersede or tend to supersede the patent assigned. The deed also set out that the Electrical Installation Company and their assigns, should keep proper books in respect to manufacture and sale under the patent, plaintiff to have access to them. By his statement of claim the plaintiff said that the defendant O'Brien Electrical Company, Limited, became successors and assigns of the Electrical Installation Company, Limited; he said the defendants were guilty of breaches of covenant by omitting to pay certain royalties and stamp duties, and to keep proper books and accounts, and he claimed to be entitled to proceed against the O'Brien Electrical Company on the ground that they were the successors and assigns of the Electrical Installation Company.

Lord Justice Smith pointed out that there was no contract for the O'Brien Company to pay stamp duty.

Lord Justice Chitty: Though I covenant that myself, and assigns will do something, my assigns are not bound by my covenant—unless it is something connected with land.

Mr. Sinclair Cox said first there was this agreement with the Electrical Installation Company, then there was a license granted by the Electrical Installation Company to Messrs. Hodgson & Todd, then there was an assignment of the interest of the Electrical Installation Company to the O'Brien Electrical Company, who were not only their assigns but also their successors.

Lord Justice Chitty: What do you mean by successors, as distinct from assigns?

Mr. Sinclair Cox: In this way. They took over the whole of the undertaking of the Electrical Installation Company.

Lord Justice Chitty: That is to say, they were assigns.

Lord Justice Smith: All you can do is to produce a contract by the Electrical Installation Company that the other people will do certain things. That is not a contract with the other people.

Mr. Sinclair Cox: I produce a contract between the plaintiff and the defendant Electrical Installation Company "and their respective assigns."

Lord Justice Smith: How can that be?

Mr. Sinclair Cox pointed out that this was not a document by plaintiff or his assigns to pay a certain sum of money. It was an agreement by which plaintiff handed over his whole interest in a patent, so as to prevent himself from in any way being concerned with the manufacture of anything under the patent, and he not only did that in respect to the Electrical Installation Company, but in respect to their assigns.

Lord Justice Smith: Where is the contract between the O'Brien Company and you?

Mr. Sinclair Cox argued that the O'Brien Company became the successors of the whole undertaking of the Electrical Installation Company, which had disappeared into them, and he submitted that he was entitled to go against them.

Lord Justice Chitty: I was looking to see if there were any negative covenants, but there are none.

Mr. Sinclair Cox submitted that there were both affirmative and negative covenants. If he might cite a case——

Lord Justice Smith was curious to see a case in which, under these circumstances, the assignee was bound by the assignor's contract.

Mr. Sinclair Cox cited the case of Werderman v. Société Générale, but that case and the one before the Court their Lordships declared to be as different as two poles.

Lord Justice Smith: Have you any allegation in this statement of claim that the O'Brien Company took what they did take with notice of the contract?

Mr. Sinclair Cox: I say there is no direct statement of notice——

Lord Justice Smith: Then no direct notice is no notice at all.

Mr. Sinclair Cox argued that all he had to do was to show reasonable cause of action, and he alleged in the statement of claim facts from which it could reasonably be inferred that the O'Brien Company had notice of these conditions. They were successors of the original company.

Lord Justice Chitty: A phrase which I cannot for the life of me understand.

Lord Justice Vaughan Williams: Do you mean by successors that they were posterity?

Mr. Sinclair Cox said they described themselves as successors of the Electrical Installation Company, and that, he submitted, showed that they had notice of the conditions under which the Electrical Installation Company did their business, the whole of the liabilities of which they took over.

Lord Justice Smith: How can you come to a court of common law for breach of a contract between A and B which does not exist, and ask B to pay you damages?

Mr. Sinclair Cox: Because B holds the patent.

Lord Justice Chitty: If you are suing on the equitable ground of notice you ought to have stated it. Your explanation of them as successors, which I can hardly accept—it is very ingenious—you say involves notice?

Mr. Sinclair Cox said if they were successors, they succeeded to all the rights and liabilities of the company which they effaced, and amongst those liabilities was that in respect to the assignment of this patent. This case was not limited to damages for breach of contract.

Lord Justice Smith: The main part is for damages.

Mr. Sinclair Cox said the plaintiff asked for royalties due, for an account, and for a declaration that he was entitled to access to the books. If the O'Brien Company was struck out of the case, it would defeat the whole power of the plaintiff to protect himself, because the Electrical Installation Company was gone, and his rights in respect to the patent, which was now in possession of the O'Brien Company, had disappeared.

Lord Justice Smith delivered judgment, observing that the appeal must be dismissed. With any question of equity he had nothing to do; he took this statement of claim, and reading it according to its plain English, this was an action claiming damages against the two defendant companies for breach of contract. The O'Brien Company said to plaintiff, "Produce your contract that I have made with you." No such contract could be produced, because the O'Brien Company never did make a contract with the plaintiff, and the point taken was, that inasmuch as plaintiff was suing for damages he failed, because there was no contract between the O'Brien Company and himself. Plaintiff's contract was, that the Electrical Installation Company and its assigns would do certain things; and when a person entered into a contract of this nature "for himself and his assigns," his contract was that he or his assigns would do what he had contracted to do, and if his assigns did not do what he had contracted that they should do, then the cause of action was against the person contracting for himself or his assigns; it did not give cause of action against the assigns. It had been argued that plaintiff had title in equity on counsel's interpretation of "successors," as implying that the O'Brien Company had notice, and if plaintiff by amendment or alteration could make out another cause of action against the O'Brien Company, well and good; but at present he had not done so. In his judgment, the order that the O'Brien Company should be struck out of the claim should stand, plaintiff having leave to amend, this appeal being dismissed with costs.

Lord Justice Chitty was of the same opinion. Neither in law nor equity could a man covenant for his assigns so as to bring them by his covenant into his contract; there must be an independent contract between them. It might be that plaintiff might make out a case in equity by proving that the O'Brien Company had notice, but there was no allegation of notice in this claim; and if he intended to set up equity against the O'Brien Company, it ought to have been done in a manner which was not done in this case.

Lord Justice Vaughan Williams concurred, holding it to be a fatal defect in this claim that there was no allegation that the O'Brien Company took the assignment with notice of the antecedent agreement.

Lord Justice Smith observed that while this judgment held Mr. Justice Darling's order to be right and dismissed the appeal, if Mr. Justice Darling thought fit to grant plaintiff indulgence to amend he might do so.

Mr. Wallace said no question of amendment was raised in Chambers.

Mr. Sinclair Cox: I understand your Lordship to say I shall have leave to amend?

Lord Justice Smith: Yes; apply within seven days.

Colman v. Kempe.

On Saturday in the Queen's Bench Division, before Mr. Justice Day, sitting without a jury, the case was heard of Colman v. Kempe. This was an action brought by Mr. Alexander Colman against Mr. Harry Robert Kempe, to recover £98 4s. 2d., commission earned as advertisement agent in connection with the "Engineers' Year Book," of which publication the defendant was proprietor. The question turned upon the construction of a contract in writing made between the plaintiff and defendant in January, 1894, by which the plaintiff had been appointed sole advertisement agent of the defendant, the plaintiff contending that having been appointed sole agent he was entitled to receive commission on all advertisements sent to the "Engineers' Year Book," and the defendant contending that he was not entitled to receive commission on advertisements obtained by his employer without the plaintiff's intervention. It appeared in the course of the evidence that the plaintiff had issued a number of circulars for the purpose of obtaining advertisements, and it was upon the advertisements obtained through the medium of these circulars, amongst others, that he based his claim.

His Lordship gave judgment for the defendant. He said that the plaintiff, having been appointed sole agent, would have been entitled to resist the appointment of another agent, but that although sole agent he was not entitled to commission upon orders for advertisements received by the defendant without the intervention of the plaintiff. Judgment accordingly.

Mr. Cagney and Mr. Ritter were counsel for the plaintiff, while Mr. Bray, Q.C., and Mr. Hume Williams represented the defendant.

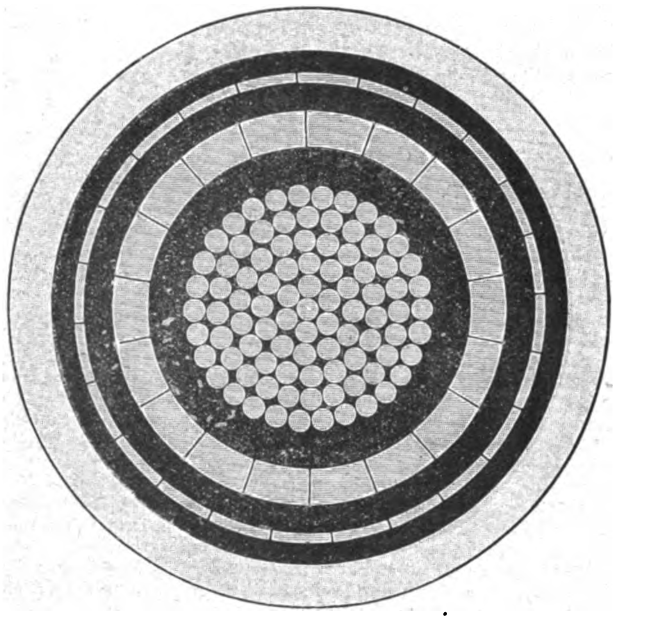
Auction Sale.—Messrs. Percy Huddleston & Co. are to sell by auction seven tramway cars and a quantity of electrical plant, including dynamos, motors, arc, and incandescent lamps, carbons, switches, numerous fittings, cables, &c. See our "Official Notices" for particulars.

B. I. Cables for Glasgow.—The illustration shows the full size section of the triple cable recently supplied for Glasgow by the British Insulated Wire Company. This cable has a sectional area on each of the inner conductors of 1 square inch, the neutral or outer conductor having an area of ·3 square inch. The net weight of



the cable, exclusive of drums, is 45 tons per mile, and it is believed that this is the largest cable that has yet been built. The whole of it was tested at a pressure of 2,500 volts for 15 minutes before leaving the factory, and we understand that a sample of the cable was, in Mr. Chamen's presence, bent six times in opposite directions round a 3 feet barrel, and the insulation afterwards withstood successfully a pressure of 30,000 volts alternating for 10 minutes.

Books Received.—"Elementary Chemistry: Practical and Theoretical." (First year.) By T. A. Cheetham, F.C.S. Published by Blackie & Son, 50, Old Bailey. Science Hand-books Series. 1s. 6d.

"The Electric Wiring and Fittings Details Book." By W. Perren Maycock, M.I.E.E. Published by Whittaker & Co., London. 2s. 6d. net.

"Electro-Dynamics. The Direct Current Motor." By C. A. Carus Wilson. Longmans, Green & Co., Paternoster Row. 7s. 6d.

Catalogues and Lists.—Messrs. Dobsons & Curtis Bros., Limited, of Dublin, have issued a second edition of their illustrated catalogue of electric lighting supplies. The list includes a variety of electric lighting switches, wall plugs, cut-outs, and other fittings of that character, also lamps, brackets, pendants, &c. The firm has recently opened an electrical fittings showroom in Stephen's Green, Dublin, where a large varied stock of electric lighting fittings and supplies is kept. The firm makes a speciality of switch and distributing board work.

A splendid volume of several hundred pages has been issued by Messrs. Ernest Scott & Mountain, Limited, in which are bound together sections 1, 2, 3, 4, 5 and 10 of their catalogue. The electrical trade is well acquainted with the class of work made at the Close Works, Newcastle-on-Tyne, which is mainly in heavy electrical engineering plant and machinery. The compilers have aimed at making the book a useful work of reference for civil, consulting, and electrical engineers, shipbuilding firms, and buyers of machinery generally, and we think they have achieved their object. Section 1 is a useful collection of general information on several important points. It gives a comparison of the relative costs of gas and electricity, and some instructions by Mr. Mountain for fixing and working dynamo-electric machines; the notes for dynamo attendants as to current required for various sized lamps, loss in cables, &c., are sure to be of use. Section 2 is mainly devoted to the "Tyne" dynamo machines and combined engines and dynamos. Sections 3 and 4 are the more interesting, dealing with the electric transmission of power, and steam, gas, oil, and other motive power plants. In the former section are some general remarks regarding the application of electric motors to various industrial purposes, general instructions are given for ordering dynamos for these classes of work, and rules given for finding the power required to drive a dynamo, the power obtained from motors, the loss in volts in a cable, and the loss in watts in a cable. Electric pumping machinery, winding and haulage plant, cranes, hoists, portable drilling machines, coal cutting, ventilating and other machinery and apparatus driven by means of electric power are among the many items of interest in this excellent catalogue. There are numerous illustrations, and among these we particularly notice a full page group of eight 60-H.P. electric motors of special vertical type, which have been constructed by Messrs. Scott and Mountain for Messrs. Smith's Dock Company, Limited, of North Shields. Estimates appear for electric welding plants of several sizes. Section 4 describes steam engines and boilers, gas engines, oil engines, turbines, &c. Section 5 is devoted to arc lamps and accessories, projectors, accumulators, wires, and cables. Engineering specialities and machinery in general come in for treatment in Section 10, various types of steam engines, electrical and steam fans, pumps, condensers, combined engines and dynamos, being described and illustrated, and detailed accounts are also given of various colliery electric plants which have been installed by the firm during the past few years. These brief notes will suffice to give an idea of the vast amount of interesting matter which the book contains, and its service to electrical engineers and the others for whom it has been prepared is a foregone conclusion.

Messrs. Miller & Woods, of Gray's Inn Road, have issued a circular on electric signalling through space, describing their transmitter, receiver, and Tesla transformer for this purpose.

Church Lighting.—The contract for the electric lighting of the Trinity Church House, Great Portland Street, W., was placed in the hands of Mr. Leo Sunderland, of the Brush Electrical Engineering Company. The building contains a large public hall, with extensive gymnasium, class rooms, reading rooms, and residences for the clergy, and is wired for about 280 lamps. Mr. Sunderland has lately completed the lighting of St. Paul's Church, Clerkenwell; St. Paul's Church, Camden Square; the Church of the Smithfield Martyrs; St. Stephen's Church Room, East Putney.

The Edison and Swan United Electric Light Company have brought out a screw leaflet (No. 101) in which they show various screws, terminals, &c., manufactured at their Ponder's End works, where there has been put down special automatic stamping, piercing, and screwing plant. The list illustrates and gives prices per gross of binding screws and clamps and cable connections.

Electricity in Cork.—The contract for fitting the Cork Cold Storage Company's premises with electric motors, mentioned by us last week, has been given to the Cork branch of Messrs. Handley and Shanks, of Dublin. This factory, we understand, will be the first requiring over 100 effective horse-power to be driven entirely electrically in Ireland.

Fritsche's Motors.—Messrs. Wilhelm & Co., 11 and 12, Westmoreland Buildings, Aldersgate Street, E.C., have been appointed agents for the sale of Fritsche's electric motors for continuous current. They have issued a list of various types, starting at $\frac{1}{16}$ B.H.P., giving all necessary particulars and prices.

The Heilmann Company.—The Heilmann Company is about to be reconstituted and additional capital introduced.

Liquidation Notices.—A general meeting of the Thetford Electric Light and Power Company is to be held at the offices at Thetford on June 17th, at 12.30, to hear an account of the winding up from Mr. Lovewell Blake, liquidator.

A meeting of the Manchester Edison-Swan Company is to be held at the offices of Messrs. Needham, Parkinson, Slack & Needham, solicitors, 10, York Street, Manchester, on June 15th, at 12 o'clock, to hear an account of the winding up from the joint liquidators, Messrs. Gover & Sharples.

Creditors of the British Electrozone Corporation must send particulars of debts and claims to Mr. A. E. Edwards, liquidator, 8, Trafalgar Buildings, Northumberland Avenue, Charing Cross, W.C., by June 25th.

Machinery Users' Association.—We have received the report of this Association for the year ending March 31st, 1898, which was presented to the annual general meeting held at Westminster Palace Hotel on Wednesday. The report shows the work done during the year in the way of negotiation, legislation, and litigation for the furtherance of the objects of the Association.

Mavor & Coulson.—This firm have brought out a somewhat elaborate book of 60 pages, in which they describe at length, with the aid of some good illustrations, the various departments at their new works at Glasgow, which we have already illustrated in the Electrical Review. The arrangement of the matter and blocks is neatly done, and a thick glazed paper is a great advantage to the production.

Three-Phase Plant.—The Bristol Waggon and Carriage Works Company, Limited, of Bristol, have placed in the hands of Messrs. Thos. Richardson & Sons, of Hartlepool, a contract for putting down a three-phase plant for electric lighting and machine driving at their works. The aggregate power of the motors will be 230 horse-power, and for lighting the works there will be used 20 arcs and about 759 glow lamps. The power is at present generated by five Lancashire boilers, with an equal number of engines. By the adoption of electricity the economy in steam will, it is claimed, be such as to enable the whole of the power, including the lighting, to be supplied by one Lancashire boiler, while the total saving effected, after allowing for all charges, will be considerably over £1,000 per annum. Notwithstanding this saving in steam power, it is anticipated that the present machinery, with the improved driving arrangements, will produce from 10 to 20 per cent. more work. The generators and motors will be supplied by Messrs. Richardson, of Hartlepool. The boiler will be fitted with a Bennis automatic stoker and Green's economiser, while a Bennis automatic damper regulator will be provided in the main flue. The engine will have horizontal compound side-by-side cylinders, and in order to provide spare power for extension it will be capable of developing a maximum of 400 indicated horse-power. This contract has been placed in the hands of Messrs. Geipel & Lange, London, who are Messrs. Richardson's agents.

Wireless Telegraphy.—The first installation of Marconi's wireless telegraph system in Ireland for business purposes was made at Clara, King's County, last week, at Messrs. Goodbody's factories, the transmitter being placed at their flour factory and the receiver at their jute works, a mile away. It is reported to have worked most successfully.

ELECTRIC LIGHTING NOTES.

Alderley Edge.—An early start is to be made with the construction of the electricity works at Belmont, and it is expected that current will be available before the end of the year. The plant to be put down will supply 5,000 8-C.P. lamps, and the three-wire continuous current system, with feeders, is to be adopted. The mains will first be laid along London Road and Macclesfield Road to Underwood Road, meeting others laid in Woodbrook Road, and continuing to Rookwood, Trafford Road, Hey's Lane, Wilmslow Road, and Brook Lane.

Amblecote.—The District Council having been requested to join the Kingswinford Council in getting a provisional order for the electric lighting of the district, has resolved not to withdraw its opposition to the application of the Kingswinford Rural District Council for lighting powers so far as Amblecote is concerned.

Bangor.—The City Council has resolved upon the extension of the electric lighting scheme to Upper Bangor, and to amend the application already made to the Local Government Board for sanction to borrow an additional £3,500 for this purpose.

Barnsley.—The Council adopted the electric lighting scheme proposed by Mr. Miller, on Tuesday last week. Mr. Miller's report recommended the three-wire direct current system, with 230 volts at consumers' terminals. This system, he mentions, would also be suitable for electric traction, if adopted. The plant proposed would supply current to 6,000 8-C.P. lamps, and will comprise three Lancashire boilers 7 feet 6 inches by 28 feet, working at a pressure of 160 lbs. per square inch, and one economiser having 192 pipes; three sets of 125 I.H.P. steam engines, each coupled to a shunt-wound dynamo of 75 kw. capacity. There will be two batteries of accumulators, each consisting of 125 cells, and having a capacity of 500 ampere-hours; and there will be two transformers to raise the pressure for charging from the station 'bus bars. Two balancing transformers will regulate the pressure on the two sides of the three-wire system. The site for station is situated at the Town's Yard. The total cost is estimated at £23,322. The capacity of the plant could be doubled by an outlay of another £2,000 on plant and £500 on buildings. For public lighting it is proposed to employ 10-ampere arc lamps for lighting the main streets, and incandescents for the smaller streets. There would be 35 arc lamps, complete with cables, &c., to cost £45 each, and 30 incandescents at £4 per lamp, the total cost being £1,695. The maintenance and interest and repayment total out at £2,820 per annum. The revenue is estimated at £3,000. 7d. per unit will be charged for the first hour, and 3d. after.

Belfast.—The Electric Committee recommends the adoption of the Wright charging system, 7d. to be charged for the first hour and a half, and 2d. afterwards; power will be 4d. and 1½d. per unit on the same conditions. The matter comes before the Council in June.

Birmingham.—It is stated that the General Purposes Committee and the Birmingham Electric Supply Company have arranged terms for the purchase of the company's plant and business by the Corporation. The conditions have yet to be submitted to the Council and to the company's shareholders. The matter has been in the hands of a Committee for the past 12 months. The Birmingham *Mail* says that the terms of purchase are on the basis of £10 10s. per £5 share, which is about their actual Stock Exchange quotation, and but little, if at all, in excess of the market value of a gilt-edged and improving 5 per cent. security. On these terms, if they are accepted, there can be no question that the Corporation would secure a bargain for the ratepayers, seeing that the company's dividend is an advancing one, and that the needful money can be raised for considerably less than 3 per cent. For 1891, the first year of the company's existence, the net profit earned was only £361. For 1892 a dividend of 3½ per cent. was paid. For each of the three following years the distribution was at the rate of 4 per cent. For 1896 it was raised to 4½ per cent., and last year's dividend was at the rate of 5 per cent., with a balance of £1,042 carried forward. The capital expended on works to the end of last year was £215,050, in addition to £4,027 spent in obtaining Parliamentary provisional orders, and the total assets were valued at £244,504. At the annual meeting, in March last, the directors were authorised to raise the capital of the company to £300,000, by the creation of 20,000 additional ordinary shares of £5 each, but it was understood that nothing would be done in the matter until the issue of the negotiations with the Corporation was known.

In regard to the above statement, the Lord Mayor at Monday's meeting of the General Purposes Committee made it clear that *no* provisional agreement had been entered into with the company. It is understood that Mr. Harris (of Bramwell & Harris) has not yet officially submitted the results of his investigations as to the position of the company. It is expected, however, that the matter will be ripe by the middle of next week, and may come before the City Council at the June meeting.

Bournemouth.—The Town Council have under consideration the appointment of an electrical inspector, but are deferring it until their installation for lighting the pier and gardens is laid. Messrs. Cash & Co., who tendered for this work, having notified that their tender would be increased, and the Electric Light Company declining to do the work as the Council proposed to generate their own supply, the Town Council on Wednesday (May 18th) decided to advertise for fresh tenders.

Bradford.—It has been resolved to light the Bolton Road tramway route from Foster Square to Peel Park Gates, and the Horton route from the bottom of Morley Street to Laisteridge Lane, by electricity—a total of 40 arc lamps being placed upon the poles to be erected for carrying the electric cable for working the tramways, the total estimated actual cost of this lighting being £500 per annum.

Bridlington.—On Saturday night last there was a trial of the new electric light installation on the New Spa, and the whole length of the promenade will in future be lighted by electricity.

Bromley.—Mr. W. A. Dickinson has written to the District Council on behalf of the ratepayers and inhabitants of Bromley, to strenuously protest against the proposed erection of electricity works, with chimney shaft 120 feet high, in the centre of the town.

Camberwell.—The General Purposes Committee reported at last week's Vestry meeting that the Board of Trade had conditionally approved the alternating current system of the County of London Electric Lighting Company, and to the use of an earth connection on the system of mains on the extra high pressure system.

Cardiff.—The Corporation is giving public notice that next month it will apply to the Board of Trade for permission to alter the standard pressure at which energy is supplied. No change will be made in the supply to premises which have used current since March 4th, 1596, without the consent of the consumer.

Clonakilty.—The Town Council is of opinion that there should be some improvement in the lighting of the town—oil lamps are now used—and electric lighting is favoured. The Council has been in communication with Messrs. Handley & Shanks, electrical engineers, of Cork, who put forward a scheme estimated to cost £2,750. The Council has appointed a committee to inquire into the subject.

Cork.—The governors of the Cork District Lunatic Asylum held a special meeting the other day to consider the question of lighting the Asylum by electricity. Reports on the subject had already been received from two experts, and a detailed scheme submitted by the Cork Electric Tramway and Lighting Company. The company went very closely into the present gas lighting system and compared it with the electric lighting proposals put forward by them, showing the advantages of the latter. After a very lengthy discussion the governors resolved that it would be unwise to enter on this matter at present. The total cost per annum to replace the present lighting, including all renewals, was put at £561 odd. To run three 30-inch fans, each with a 2-H P. motor, the total yearly cost is estimated at £132.

Cromer.—At the last Council meeting the clerk submitted *précis* of Mr. Gibbon's letter of March 24th, with the draft agreements and scheme as to electric lighting. After discussion, the surveyor was directed to report as to the cost of necessary works for establishing an electric light installation in the town.

Derby.—The Derby School Board contemplate introducing the electric light in some of the public schools of the borough, and at the meeting of that body on Monday afternoon a discussion took place as to the advisability of adopting the new illuminant in place of gas, and tenders were received for wiring the Traffic Street Schools, these ranging from £474 downwards. It was pointed out that the matter was proposed as an experiment, and on the ground that there was no immediate hurry, as the summer was coming on, it was resolved that the question be postponed. The chairman expressed the opinion that the experiment should be tried upon the new Orchard Street Schools.

Douglas.—Prof. Fleming, who has been consulted by the Corporation, recently visited the island, obtaining information on which to base his electric lighting report.

Durham.—Although the City Council at its last meeting apparently shelved the question of introducing electric light into the city on account of the satisfactory reports given in respect of several trial incandescent gas burners, those interested in the matter are keeping the agitation alive. Alderman Jepson, M.D, one of the leading spirits of the Council, has ascertained from Messrs. Edmundsons, of London, that street lighting in the city, which now costs £3 per lamp per annum, can be done cheaper by electricity, and that the firm are willing to introduce into any agreement that might be drawn up between them and the Council, a purchase clause. Alderman Jepson is taking steps to arrange a public meeting for the purpose of hearing an address from an electrical expert, and he hopes, by making plain the advantages of electric light, both as regards efficiency and cost, to bring about its introduction into the city at no distant date.

Folkestone.—The Lighting Committee estimate that an additional £1,500 will be required this year to pay for the extra cost of lighting the streets by electric light.

Germany.—A new central station has just been completed and put in operation at Wiesbaden. The plant, which has a capacity of 11,000 incandescent lamps, has been established by Messrs. W. A. Lahmeyer & Co., Frankfort-on-the-Main.

Glasgow.—The collection of electricity rents to date amounts to £30,386, an increase of £5,661 over the corresponding period of last year.

Glasgow.—A Sub-committee of the Corporation Electricity Committee has been appointed to confer with the Partick authorities regarding the proposal that the city should exercise the burgh's powers under its provisional order, and supply the burghal area with electric light. Negotiations are still proceeding with reference to the Clyde Trust's request for a rate, and a large engineering company have asked for a rate for about 600 horse-power to drive a portion of their machinery.

Hammersmith.—The Vestry's installation has been supplying current for private lighting for just over nine months, and for public lighting about six months, and the chief engineer now reports that up to the present time an average price of only 4½d. per unit has been received from private consumers, being the lowest obtained by any London municipal authority whose accounts have been published. The charge to the lighting rate is only £22 10s. per lamp per annum, as against about £40 per lamp per annum obtained by other authorities.

Hanley.—The Town Council is reducing the charge for electric motive power to 2½d. per unit for four hours per day, and 1d. per hour afterwards. The engineer is to approach the authorities of Stoke and Burslem with a view to ascertaining if they are willing to take electric current from Hanley in lieu of erecting separate stations for themselves.

Hove.—The Hove Electric Lighting Company having announced their intention of laying certain new mains, a member of the Council at its last meeting endeavoured to raise the question of the purchase of the electricity works by the town. Would it not be better, he asked, to purchase now, than wait till these mains had been laid down, and the cost had consequently increased? He was ruled out of order as the matter was not on the agenda, but there is little doubt that Hove will, before long, purchase the electricity works for the town.

Hull.—At a meeting of the Electric Lighting Committee on 13th inst., the chairman (Mr. Skinner) in presenting the annual accounts said that they commenced the year with the carrying out of a large extension of the electric system to the west and the northward, estimated to cost £40,690, for which they had borrowing powers. These works were well in hand, the buildings were nearing completion, and the equipment was proceeding with due despatch, and in a very short time they hoped to be able to put to use this latest addition to the enterprise and energy of the Corporation. During the year they had had, with scarcely an exception, a continuance of the support so largely given to them before, supplemented by 134 new users, and 65 old customers who had increased their lighting, while many of the new customers required a very large supply. No accident or serious breakdown had occurred during the year. The total working costs were slightly in advance of last year, but this was more than accounted for by the increase in salaries and wages, by a heavy rateable charge, and by the necessity cast upon them of providing a supplementary plant to keep pace with the demands for current. The temporary works, erected in North Street for this purpose, had cost a sum of about £900, all of which had been charged to revenue account as repairs and maintenance. At the close of the financial year they reduced the charge for motive power. The total expenditure on capital account now amounted to £61,738, of which £14,153 had been spent during the year under consideration. The total received for the 12 months was £10,453, and the expenditure £5,450, leaving a balance of £5,003, out of which, after paying £1,496 interest on loans, and £1,457 contribution to sinking fund, the committee were left with a net profit of £2,040 for the year, to be carried to reserve. The increased demand being made for the current, even at this season, and the pledge made to the residents of East Hull, made it necessary that they should take in hand very shortly a further extension, and this was accentuated by the difficulty in obtaining electrical machinery quickly. The electrical engineer submitted an analysis of the works' costs during the 12 months ended March 31st, together with a comparison for the three previous years, as under:—

	Units sold.	Works' costs.	Rents, rates, &c.	Management expenses.	Total per unit.
		d.	d.	d.	d.
1894-5 ...	163,857	2·09	0 21	0 56	2 86
1895-6 ...	246,277	1·95	0·14	0·61	2 70
1896-7 ...	340,439	1·62	0·15	0·54	2·31
1897-8 ...	467,352	1·63	0·38	0·57	2 57

The committee regarded the reports as very satisfactory. The electrical engineer submitted a report, in which he recommended a further extension of the generating plant for the purposes of extending the electric light to East Hull. The engineer reported that on March 31st last the lamps actually connected to the mains were equivalent to 43,534 8-C.P.; applications to be connected with present mains, 17,666 lamps; and on the east side of the river Hull applications for 2,520—in all 53,720 lamps, against which the present capacity of supply is 36,666 lamps. Application to the Local Government Board had been made for sanction to borrow £10,000 for the extension to East Hull, but the sanction had been temporarily withheld till full details of the scheme should be submitted. The engineer urged that the time had now arrived to pursue the matter, and to consider the question of laying down additional mains, and he recommended a scheme modified from that of 1896. With regard to the sub-station, instead of placing it on the Holderness Road, as he formerly proposed to do, he recommended that it be placed as near as possible to the North Bridge on the west side of the river, so that the cables crossing the river should carry low tension current only, the cables to be laid side by side with the tramway feeder cables. The engineer's report also fully dealt with the details, and concluded by stating that the sum of £10,000 applied for would not be sufficient to cover the cost of the extensions now recommended, and that £26,000 would be needed. The report was received and adopted, and a resolution carried to apply to the Local Government Board for borrowing powers to the extent suggested.

Hyde.—The Council has appointed Messrs. Lacey, Clirehugh & Sillar as consulting electrical engineers.

Ipswich.—Last Friday the Board of Guardians had a long discussion regarding the scheme for electrically lighting the new workhouse. Tenders were sent in by Messrs. Laing, Wharton and Down, who quoted £3 583; Edmundson's Electricity Corporation, £3,208; and Crompton & Co., who quoted £3,035, less £220, if boilers made by Messrs. Taylor & Sons are supplied. The Committee had recommended that Messrs. Crompton's tender with Taylor's boilers be accepted. After discussion the matter was referred back, several speakers considering the outlay too heavy for them.

Keswick.—The *London Gazette* contains notice of the intention of the Urban District Council to transfer their 1896 electric lighting order to the Keswick Electric Lighting Company, Limited, for a period of 42 years. The company pays £520 for the order.

King's Norton.—The District Council's provisional order was passed by the Chairman of Committees in the Commons last week.

Lambeth.—The Vestry has approved of the plans of the generating station buildings to be erected by the South London Electric Supply Corporation.

Marylebone.—The Marylebone Vestry have agreed to let the Metropolitan Electric Supply Company lay a cast-iron conduit from their station in South Street, Manchester Square, to their station in Rathbone Place, according to a route prepared by the Vestry's surveyor, which is a diversion of that proposed by the company's engineer.

Matlock Bath.—The District Council decided last week to oppose the General Power Distributing Company's Bill.

Morecambe.—At the monthly meeting of the Morecambe District Council on May 9th, the manner in which the contract for the installation of electric light has been carried out was again referred to. Mr. Parkinson read a report of his recent visit to Colchester to test the first two sets of engines. He submitted the engines to a four hours' run and found one set satisfactory, so far as speed efficiency went. The other one he found required 440 revolutions per minute instead of 400 in order to obtain the full output. There were a number of details which he refused to pass, and gave orders for them to be remedied. He was of the opinion that the sets were smaller than those which had been ordered. He would recommend the Council to take the lesser dynamos from Mr. Parker with an abatement on each set, say, of £200. Mr. Parkinson said he would not like to promise definitely for Whit week, but if they got the two sets of engines last week they would be able to light 50 lamps for that time. In committee it was afterwards resolved that Mr. Parkinson, electrical engineer, test the steam dynamos up to the specified speed, and that he report the result to Messrs. Parker, Limited, and the Electric Light Committee. The tender of Messrs. J. Ash & Son, of Birmingham, for the construction of a tank at the electric light works was accepted. It was resolved that Mr. Parkinson write to Mr. Parker urging him to come over at once to meet the Council to discuss the question of the flue, as the matter was assuming a very serious aspect.

Newport.—At a recent meeting of the Electricity Committee, the consulting engineer, Mr. Robert Hammond, submitted a lengthy report upon the question of extending the low tension mains and the construction of sub-stations in Commercial Road. At the present time this district is served as follows:—(*a*) From Hill Street to Cardiff Road by the low tension network of small capacity, fed by three isolated underground transformers, this being the usual pioneer system. (*b*) From Cardiff Road to Constable's Lane direct from the high tension mains, the high tension being converted into low tension on the premises of the consumer. Mr. Hammond says that the policy that is generally adopted in connection with the system in use at Newport, is wherever the load shows signs of density, to replace isolated transformers with larger size transformers fixed in sub-stations and feeding on to a low tension network stretching about a quarter of a mile in each direction. Under this system the amount of electricity lost in conversion from high tension to low tension is minimised, as the larger the transformers the more efficient they are. As the demand is likely to be considerable in this part of this district, it is absolutely necessary that the distribution system should be put upon such a basis as to cope with a large number of lights, and the sooner this is done the more economically and efficiently that district will be served. The distance being one mile it would be impossible, without an immense expenditure in copper, to deal with it by low tension from one sub-station, and it is therefore necessary to feed from two sub-stations. Sites have been found for these in Cardiff Road and Albion Street. Mains capable of dealing with a load many times that now obtaining have been included, and it is also proposed at the same time to lay two new feeders from the generating station to the new sub-stations. Mr. Hammond recommended that the order for the cables be given to Messrs. W. T. Glover & Co. The recently sanctioned mains extensions include high tension service mains in Alexandra Road, which would be connected up to, and fed by, the existing high tension feeders above mentioned. These will continue to do good service in the more distant district. Mr. Hammond has considered the possibility of drawing the new feeders into the 3-inch pipes already carrying one high tension feeder and one a main each; but fears such a course would lead to the almost certain destruction of the present mains, and has therefore allowed for the new mains to be laid quite independently, and on the solid system. Estimated cost of proposed extension of sub-station system and low tension distribution in Commercial Road:—Cardiff Road sub-station:—Distributors with trenching, £1,300; brick boxes, £50; altering services, £50; feeder (with trenching beyond L.T. main), £280; sub-station equipped, £800; extra feeder panel at sub-station, £40 = £2,520. Albion Street sub-station:—Distributors with trenching, £965; brick boxes, £25; altering services, £100; feeder (without any trenching), £360; station equipped, £675; extra feeder panel at station, £40 = £2,165; plans, engineering fees, contingencies, &c., £315 = £5,000. It was resolved that the report be received and adopted, and that the work which, with contingencies, is estimated to cost £5,000, be carried out as extras to the contracts of Messrs. Glover & Co. and the Electric Construction Company. In due course the committee's report came before the monthly Council meeting this week, and it was adopted. Although the electric light was only installed in 1895, it has already been found necessary to spend £30,000 in extensions, and the £5,000 authorised above will be an addition to the £30,000.

Paddington.—The Board of Guardians has referred it to the visiting committee to consider and report as to the advisability of providing the necessary electric lighting plant, &c., for the electric lighting of the workhouse and infirmary.

Pemberton.—The District Council has appointed an Electric Lighting Committee to inquire into the subject.

Peterborough.—The Town Council last Friday had a discussion *re* the appointment of an engineer in connection with the electric light undertaking. There was a proposal that Mr. J. C. Gill, C.E., who seems to hold the positions of water-works engineer and superintendent of the fire brigade, be paid an extra £50 per annum to look after the electric lighting undertaking until a profit is earned. This, however, was not passed, a counter-proposition to the effect that £100 per annum be the salary, being carried by 10 votes to five. The Council some time ago retained Dr. Fleming as consultant, and he is to continue in that capacity.

Pietermaritzburg.—Customers are applying for current in earnest now; already there are over 1,100 lamps connected to the old plant, and over 1,700 lamps ready for connection to the new plant, which is expected to be started in June. Messrs. Mowat & Still are very busy, having over 800 lamps of 8 C.P. already erected. They are also erecting 100 temporary lights and complete steam plant for the forthcoming Agricultural Show in May Week, and they have erected two very handsome arc lamp columns outside the Legislative Assembly, one on either side of Her Majesty's Statue, with the requisite underground piping and mains, and connected the Legislative Assembly with the Corporation transformer sub-station by means of a lengthy concentric armoured cable of large size. Other contractors are equally busy, and prospects for the industry look bright. The borough electrical engineer has adopted a very good and fair set of wiring rules, which ensures good work being done, and the best of materials being used, a strong contrast to other towns in South Africa, especially Johannesburg.

Poplar.—The Electric Light Committee's action in advertising for a resident electrical engineer to devise and supervise an electric lighting scheme, was approved by the Board of Works last week.

Portsmouth.—The Electric Lighting Committee proposes to borrow £5,000 for laying mains in additional thoroughfares. A committee is considering the desirability of electrically lighting St. Jude's Church, Southsea.

Mr. H. G. Burr has been appointed clerk of works for the extension of the electricity station. A building adjoining the station has been purchased for £325.

Provisional Orders.—The Bill to confirm provisional orders made by the Board of Trade relating to the burghs of Hamilton, Airdrie, Brechin, and Rothesay passed the Committee on Unopposed Bills on Wednesday last week.

On Monday the Bill to confirm the Bermondsey and Marylebone Provisional Orders was read a first time in the Commons.

A Bill has been introduced to confirm provisional orders made by the Board of Trade under the Electric Lighting Acts relating to Chelmsford, Melton Mowbray, Norwich (Extension), Preston (Extensions), and Warrington.

Radcliffe.—Mr. F. F. Bennett, consulting engineer, of Manchester, has been instructed to advise the Radcliffe Urban District Council on electric lighting, and to attend the Local Government inquiry.

Railway Train Lighting.—The question of train lighting recently occupied the attention of the South Indian Railway Company, and the matter was referred to the company's consulting engineer in London, Sir George Bruce, who advises the equipment of mail trains running between Madras and Tuticorin as a tentative measure, the equipment of the whole service to be decided by the result of the experiment.

Reigate.—Last week the Town Council held a special meeting to consider the minutes of the Electric Lighting Committee. Prof. S. P. Thompson was, on March 28th, engaged to advise the Council on the electric lighting question, and on April 25th the report was submitted, in which the Professor referred to the report prepared by Mr. Medhurst in November, 1895, and after considering the requirements of Reigate and Redhill at considerable length, he expresses the opinion that Mr. Medhurst's scheme was a well-advised one. On May 4th it was resolved to instruct Mr. Medhurst to prepare plans and specifications for the installation on the lines of his previous report, with certain modifications recommended by Prof. Thompson, and to ask him to state his terms. It was further decided to ask Prof. Thompson whether the sites of the Reigate and Redhill gas works, which the Council is thinking of purchasing, would be of any use as sites for electricity works. At last week's Council meeting Mr. Medhurst's terms were considered and accepted.

Ryde.—In officially announcing that the Board of Trade have refused an application to form an electric light and power company in this town, the Mayor, at a meeting of the Council last week, said that on consideration of what had transpired at the public inquiry it was his intention to call a public meeting to consider the matter, and decide what steps should be taken.

Salford.—On Wednesday the Salford County Borough Council considered a resolution of the Electric Light Committee, adopting the plans of Mr. John Holt, for the erection of a new generating station on land in Strawberry Road, at an estimated cost of £28,161.

Shoreditch.—At the Vestry meeting on Tuesday it was resolved, at the suggestion of the London County Council, to amend the application for a loan of £15,700 for electric lighting purposes to £16,537, so as to bring the expenditure up to March 25th, 1898. Mr. A. J. Hazell submitted the report of the Valuation List Committee with regard to the rating of the electricity works and the refuse destructor. The committee had considered a report from Mr. Mansfield Robinson (the Vestry Clerk) on the subject, and had resolved to calculate the rateable value at a 3 per cent. basis on the cost of the land and buildings, in accordance with the decision of the House of Lords in the case of the London County Council *v.* Erith. The Vestry approved this, and resolved to apportion half of the rateable value to the electric light undertaking, and half to the refuse destructor. Mr. H. E. Kershaw, who submitted the report and accounts of the Electric Lighting Committee, stated that the Vestry was to be heartily congratulated on the magnificent success during the past nine months in the sale of electricity. With regard to the wiring department there had been a loss of £158; but that branch had answered its purpose of counteracting some of the unsatisfactory practices pursued by some contractors. The results obtained were phenomenal in the history of any electric light undertaking for a period of nine months, since the gross profits amounted to £4,264, which sum, in the case of a company, would be equivalent to a dividend of 6½ per cent. After providing for redemption of capital and payment of interest, there remained a net profit of £2,072, which left a surplus of £700, after paying off the contribution from the rate. In conclusion, Mr. Kershaw mentioned that the committee had resolved to wait for 12 months before entering into the question of the cost of refuse destruction, since it would be unfair to consider the cost on anything less than a year's basis. Mr. Winkler complained of the accounts of the dust destructor not being included in those presented to the meeting, the speaker contending that the two sections of the undertaking should not be separated from each other. Nothing had been provided in the accounts for depreciation and for other items, and in his opinion the working of the refuse destructor was being carried on at a loss. Where would the surplus be at the end of the year? It would be cheaper to use coal for steam-raising purposes and to shut down the refuse destructor. He therefore moved, and it was seconded, that the accounts should be referred back in order that Mr. Adams (the accountant) might prepare a balance-sheet of the income and expenditure of the refuse destructor and electric lighting works jointly. The chairman (Mr. Wakeling) pointed out the impossibility, from a legal standpoint, of a joint report being prepared, and at his suggestion the amendment was altered in favour of a balance-sheet for the refuse destructor only being got out. Other speakers having followed, Mr. Kershaw replied to the criticisms at some length. On the amendment being put to the meeting, no votes were recorded, and eventually the report and accounts were passed.

Southampton.—The Council has resolved, upon the recommendation of the electrical engineer, that when the total number of units consumed by one consumer in any one year for lighting exceeds 30,000, the maximum charge be 5d. per unit instead of 6d. The electrical engineer recently reported that the number of units metered at the works during April was 17,468, an increase of 6,780, or 63 per cent. over the output for April, 1897; and that on April 21st the supply to the electric cranes had to be shut off for a few minutes owing to a slight accident to one of the temporary engines. During Mr. Manville's absence abroad Mr. Aldridge will look after the laying of the mains. Alderman Bone said at last week's Council meeting that the making good of the damage done by the recent accident at the works would be much less than was at first thought. With regard to the proposed alterations in charges, the Committee thought it was their duty to encourage large consumers, and they hoped that they would get one or two very large customers in consequence of the reduction.

Stafford.—The annual report of the Gas and Electricity Committee shows that during the financial year ended March 31st there was an increased amount of business in both spheres of its operations. In the electricity department the increase in the sale of current was very marked. There were now the equivalent of 6,200 8-C.P. lamps connected, as against 5,003 last year, and the current sold was 55,542 B.T.U., an increase of no less than 27 per cent., but the low tariff of charges fixed last May seriously affected the revenue. The sale of current amounted to £1,202 13s. 6d., as against £1,162 1s. 10d. last year, being an increase of £40 11s. 8d., or only 3½ per cent. The total receipts were £1,292 12s. 9d. The total expenses amounted to £765 10s. 3d., leaving a gross profit of £527 2s. 6d. Adding to this £897 16s. 3d., brought forward, the total sum standing to the credit of the electric department was £1,424 18s. 9d. Out of that sum the Committee has paid £555 19s. 5d. for interest, £436 9s. 6d. in repayment of loan, and carried forward £432 9s. 10d. The total amount borrowed was £20,000, and the sum repaid is £1,271 13s., the debt on capital account now being £18,728 7s. The electric mains are now practically at the limit of their capacity, and if the demand for the electric light continues to increase, it will be absolutely necessary to incur considerable further expense on capital account in order to increase their capacity by doubling the pressure. The boilers, engines, and dynamos are ample for a considerably greater demand, and the whole installation is in the highest state of efficiency. The chairman of the committee, Alderman W. H. Peach, is about to retire. The Corporation at the same meeting voted Mr. J. F. Bell, the manager of the works, a bonus of £250, in consideration of the extra work he has undertaken in connection with the electricity department, and also on account of great increase in gas output.

Taunton.—Mr. E B. Thornhill, the borough electrician, reports that the Free Wiring Company is making very satisfactory progress, as during the past quarter it has installed the equivalent of over 500 8-candle-power lamps. There had been connected with the mains during the quarter the equivalent of 1,541 8-candle-power lamps.

The total new connections during the month of April have been equivalent to 512 8-C.P. lamps.

Train Lighting.—The London and South Western Railway Company are fitting up some of their new triple composite coaches with electric light.

Wakefield.—Mr. Wigham, chairman of the Electric Lighting Committee, last week reported that Messrs. Fowler & Co. had delivered the two engines for the electricity works. One was working to the entire satisfaction of the Committee, and the other was being fixed. Some connections were yet to make, but that was only a matter of two or three days' work.

West Ham.—Tenders were received for electric light fittings for public buildings in the borough, as follows:—Salmony & Co., 2½ per cent. below; General Electric Company, 5 per cent. below; National Free Wiring Company, 45 per cent. below; Electrical and General Engineering Company, schedule price; Beaver & Co., 11 per cent. below; William McGeoch, schedule price; Benham & Froud, 6 per cent. above schedule; Rogers & Co., 7½ per cent. below schedule; Verity, 5 per cent. below schedule. The tenders were referred to the Highways Committee.

The Guardians have decided to light the workhouse by electricity.

Westgate.—On Friday last a Board of Trade inquiry was held by Major Cardew in the matter of the application by the Isle of Thanet Rural District Council for a provisional electric lighting order within Westgate-on-Sea. The scheme was opposed on behalf of a number of objecting ratepayers. There was a numerous gathering of ratepayers present. Mr. Bartley Denniss, who opened the case for the promoters, urged that the price of gas, namely, 4s. 9d. per 1,000, which was the maximum charge allowed by the Westgate and Birchington Gas Company's Act, was hard on the consumers. It was agreed that the more modern method of lighting, as suggested by Mr. Hawtayne, would be not only an advertisement for the place, but a profitable source of income, which would go towards the yearly diminution of the rates, the consulting engineer's figures on this point showing an annual profit of from £120 to £130 a year. It was stated that although the town was small, the rateable value was exceedingly high. The success of the scheme was practically ensured. The estimated cost was under £10,000. The majority of the objectors are interested in the gas company. Mr. Hawtayne's figures were criticised in cross-examination by Mr. Morton Smith, and Mr. F. E. Gripper, consulting electrical engineer and expert, was called to speak as to Mr. Hawtayne's estimate, and put it at £15,000 instead of £10,000. He also pointed out that the house installations would cost on an average £1 per light. He also condemned Mr. Hawtayne's estimate of the working expenses as being too low. Mr. Monkhouse (Messrs. Burstall & Monkhouse) supported this view, and other evidence having been given in opposition to the scheme, the inquiry was adjourned without any definite date being fixed.

Weston-Super-Mare.—The Board of Trade did not intend to proceed further with the local syndicate's application for a provisional order.

Whitechapel.—Notwithstanding repeated promises, the report of the Electric Light Committee is not yet forthcoming, and at the last week's District Board there were signs of growing impatience on account of the prolonged delay in dealing with the matter.

Willesden.—The Board of Trade has sanctioned the Council's provisional order.

Windsor.—The Windsor and Eton Electric Lighting Company have extended their mains down Park Street. The company has adopted the slot meter system.

Woodstock.—The Lighting Committee is negotiating with an electrical engineer as to an electric light installation for the borough.

Ulverston.—The Board of Trade has advised the District Council that as the Windermere and District Electric Lighting Company had not carried out their order of 1895, they are considering its revocation, but would like to hear the opinion of the Council. The Council thought that unless the stipulations in the order were carried out, it should be allowed to lapse.

Yarmouth.—Mr. W. H. Preece has reported to the Council upon the recent explosion at the electricity works. He was of opinion that the cause of the accident was an undue level of water in one of the old single drum boilers, and the main question was the remedy for preventing a similar accident in future. The addition of four high-level indicators would be of advantage as a safeguard against future mistakes in gauging the water level. He did not recommend the addition of separators on the ground of the extremely heavy expenditure that would be involved—£250—and any omission on the part of the engine driver to observe the level of water in the indicators would at once lead to a probable accident, and therefore introduce further danger. Mr. Preece, however, suggested an improved system of drainage, which he could conveniently include in the new extensions. Mr. Preece's report closed with the following paragraph: "It is well to bear in mind that whatever precautions are taken in arranging safety devices, such precautions are rendered useless if carelessness is shown by the workmen. It is impossible to design work which is entirely independent of this contingency."

The Electric Light Committee received replies from the Yarmouth and Gorleston Tramways Company in regard to points raised by the town clerk on their application to the Corporation in regard to the supply of electric light and power in Gorleston and Southtown. The company intimated that they would ask for an extension of 29 years beyond the time mentioned in the order, giving the scheme a total life of 35 years. The company could not pay more than the permit if they took electric power from the Corporation for the tramways. The company would undertake the supply of public and street lighting, erecting a generating station, &c. The average charge made would be 6½d. per unit. If the Corporation provided the cables and handled the supply to private consumers, the average charge would be 4½d. per unit as metered at the company's switchboard. The company offered to supply the current, to maintain and clean street arc lamps on the tops of the trolley posts, at a charge of £22 to £28 per annum. If the Corporation supplied the standards the cost would be £2 per annum less. Incandescent lamps would be supplied, fitted into the existing gas lanterns where arc lamps were not needed, at £4 per annum, where the mains were already laid. The Corporation would be asked to take over the electrical plant when exercising power to purchase the tramway equipment, under the Tramways Act, at a premium of 10 per cent. upon the cost of plant. The company was not prepared to offer any concession, monetary or otherwise, to the Corporation for surrendering its rights. On a consideration of these replies the Electric Light Committee recommended the Council to adhere to its agreement of May 8th, 1897, when an understanding was given to supply the Tramways Company with electric energy according to a graduated scale, commencing at 3½d. per unit, when the amount of energy does not exceed 250,000 units per annum. Mr. A. Peaton said that Gorleston had equal right with Yarmouth to the enjoyment of the electric light, but if there were obstacles in the way of the Corporation carrying the light across the water, the offer of a private company to do so should not be refused. He moved that a special committee be appointed to consider this matter.—Mr. Ruddock seconded.—At the suggestion of the Mayor, Mr. Peaton substituted for his amendment a reference back to the Electric Lighting Committee.—This amendment was then adopted.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

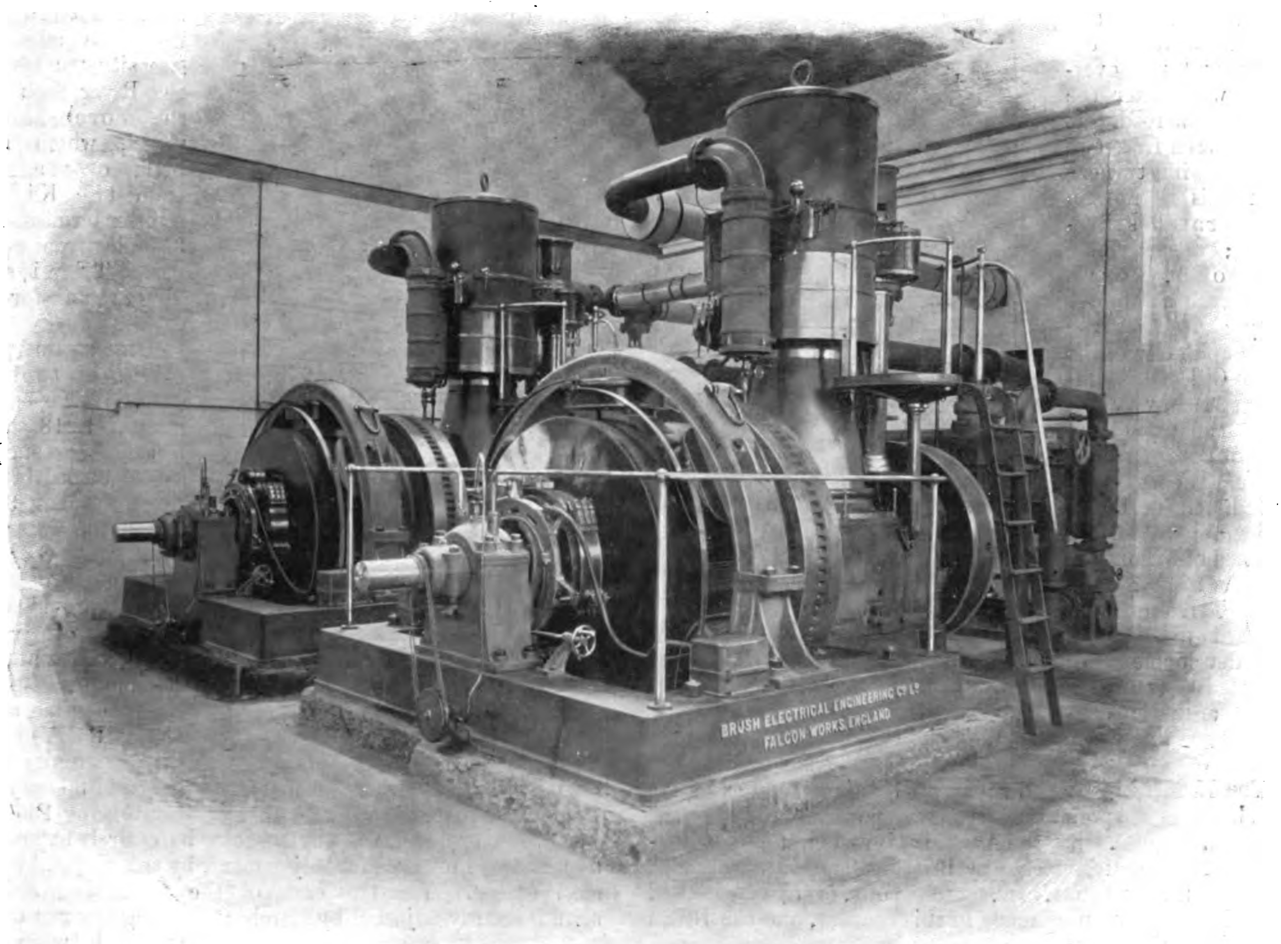
Barnsley.—Several communications respecting tramway proposals have been before the Streets, Buildings, and Improvements Committee, as follows:—(1) A letter dated the 30th ult. from the British Insulated Wire Company, Limited, asking for the consent of the Town Council to a proposed application by a company to be formed by the British Insulated Wire Company for a provisional order to enable them to construct and work tramways in the borough, and also offering certain terms in consideration of such consent; (2) a letter dated the 30th ult. from Messrs. Newman and Bond, explaining the proposals of the syndicate on whose behalf application has been made by them for the consent of the Council to an application for a provisional order; and (3) a letter dated the 3rd inst. from the clerk to the Worsbro' Urban District Council, suggesting that a conference take place between representatives of this Council and of the Worsbro' Urban District Council with respect to the provision of tramways in Barnsley and Worsbro'. These matters were to be considered by the committee at a special meeting arranged for yesterday, and each of the interested parties was invited to send a representative.

Bristol.—At the closing private meeting of the Sanitary Committee on the question of electric traction and tram extension in Bristol, all opposition on the part of the Corporation to the progress of the Tramway Company's Bills in Parliament was finally withdrawn. The opposition of private frontagers has also almost entirely disappeared. The final concessions of the company in the matter of fares are contained in a lengthy letter from the directors' solicitors to the town clerk.

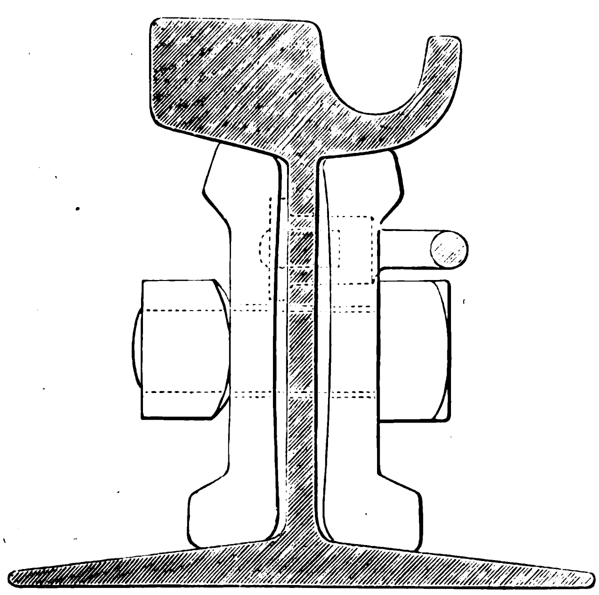
(*Continued on page* 698.)

THE KIDDERMINSTER AND STOURPORT ELECTRIC TRAMWAY.

There is not much doubt that we are in a fair way to remove the reproach that has been so often cast at this country in the matter of electric tramways. The most prejudiced patriot cannot deny that as a nation we have been slow to avail ourselves of the many great advantages offered by electric tramways. It is true that vested interests have been in a large degree responsible for the lack of progress, but after all very little has been done to bring the merits of electrically operated tramways before the public, who are the real arbiters on social innovations. With a growing disposition on the part of municipalities, however, to control and operate electrical tramlines, we are in a fair way to bring the public in much nearer relationship with the benefits of mechanical traction. At the same time, without decrying in the least the laudable efforts of town authorities, there can be little doubt that much of the future of electric traction lies in the hands of private concerns, or perhaps we had better say that much of the immediate progress that will be made in this direction we shall owe to the capitalist.

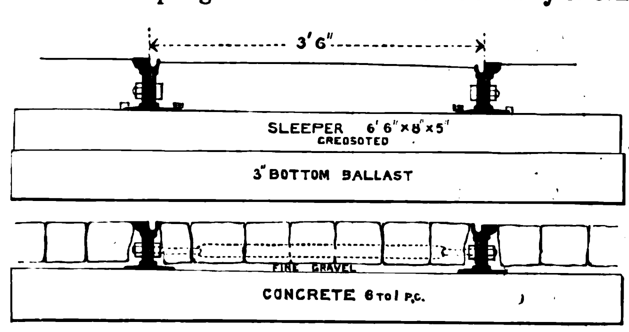


View of Generating Plant.



Section of Rail, Half Size.

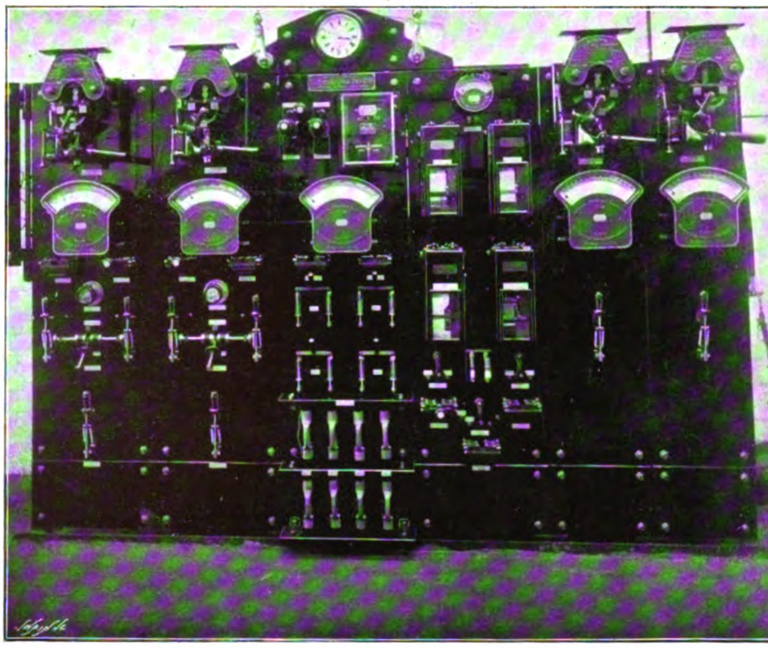
It is obvious that a municipality is bound to be more cautious in adopting schemes that call for the outlay of considerable sums of public money, consequently, municipal traction plant is of slow growth. It is quite true that the Corporations of Glasgow, Leeds, Sheffield, Dover, and Plymouth have recognised the merits of the system, but to show how much we must still rely on private enterprise, it is only necessary to say that one company alone—the British Electric Traction—probably one of the most powerful electric traction organisations in Europe, is contemplating



Details of Permanent Way.

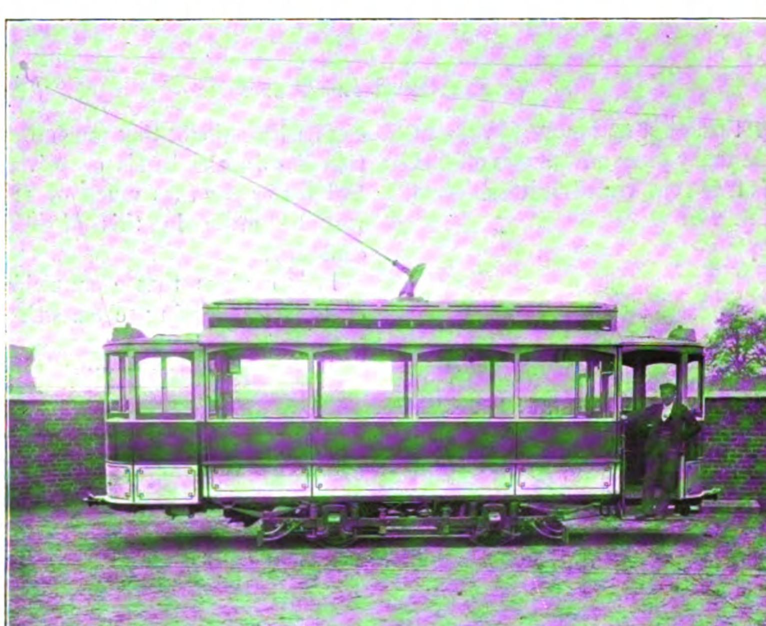
schemes which will involve an outlay of £3,000,000. The first completed system erected by this company is the one we are about to review.

The district of Kidderminster is an excellent place to demonstrate the merits of an electric tramway system. A portion of the route is a hilly one, and there is an unusual proportion of interesting scenery alongside the tramway. Hence one is able to show with what ease are gradients mounted and how little the posts and the overhead wires alter the aspect of a road. It will be seen from two of our illustrations that this is not an exaggerated statement; these views, moreover, serve another purpose—they show that the telegraph poles of the Post Office are immeasurably worse than the posts that support the trolley wire. Yet who ever heard the Postal Telegraph authorities accused of defloration of scenery? We have, however, reached a stage in the development of electric tramways when æsthetic considerations may be neglected.



SWITCHBOARD.

The Kidderminster and Stourport line is not an extensive one, but it is of special interest and importance at the present moment, because, since the American invasion, it may be considered the first line erected by British manufacturers. The steam plant, generators, cars, motors, posts, overhead wire and material all have been made in this country, and the Brush Electrical Engineering Company, the principal contractors, are to be congratulated, not only upon the successful completion of the line, but also because they have had the good sense to copy some of the best features of American practice. Prior to the introduction of the present electric system, there were no tramways in Kidderminster, the chief means of vehicular communication between different parts of the town and the outlying districts being a somewhat desultory service of omnibuses.



CAR ON LINE.

Parliamentary powers for the line were obtained by the British Electric Traction (Pioneer) Company, Limited, under whose control the system has been carried out. Commencing at Somerleyton Avenue, about half a mile in an easterly direction from the Great Western Railway station at Kidderminster, the line passes through the chief streets of the sleepy old town; past the carpet manufactories that line the outskirts of the town, along the Stourport Road, where the country opens towards the valley of the Stour, thence it traverses the crossing of the Great Western Railway, terminating in Bridge Street, Stourport, on the banks of the River Severn.

THE GENERATING PLANT.

The power house possesses features of more than usual interest, arising from the use that is made of home-made plant.

The building comprises power house and car depôt which are arranged together upon an admirable site situated between the River Stour and the Worcestershire Canal, which is a little over a mile from the Kidderminster terminus, and 3½ miles from Stourport. There is shedding room for 10 cars.

The steam plant consists of two Babcock & Wilcox boilers, each of 1,218 square feet heating surface, and capable of evaporating 3,500 gallons of water per hour. A Green's economiser of 120 pipes is provided, the scrapers of which are driven by an electric motor.

The engines are of the "Universal" single crank compound type, and have cylinders of 20 inches and 30 inches × 12 inches stroke, the working steam pressure being 135 lbs.

Though enclosed the engines can be entirely exposed in two or three minutes for adjustment, by the removal of the steel casing. The two ends of the connecting rod are simultaneously adjusted by merely tightening the nut on the strut between the crosshead and crank pins, the operation taking quite a small fraction of time.

One of the principal features claimed for the Universal engine is that fluctuation of load does not produce water hammering, the engine being automatically self-draining. Steam is admitted only to the under side of the H.P. piston, the H.P. cylinder being drained throughout the whole of the downstroke by the valve, whilst the drainage of the L.P. cylinder is effected by the piston exposing a number of holes around the cylinder when at the bottom of its stroke. This quality is a most important one, particularly in traction work, where the variations of load are severe and priming necessarily more frequent than with steady loads.

There are two direct-coupled six-pole generators provided with Mordey's new chord winding and notched armature; they work at a pressure of 550 volts, and have a normal output of 100 kw., though they are capable of working to 135 kw. without a rise of temperature exceeding 80° F.

The most noteworthy feature about the machine is that the armature is of unusually large diameter in proportion to the width of field. This allows ample room for armature winding, notwithstanding the high voltage, and renders the whole of the windings and connections extremely accessible.

Owing to the adoption of the Mordey chord winding, the field coils are extremely small, as will be seen from the illustration, and no doubt the economy of copper in this respect is very marked. Each dynamo has a single bearing of ample proportions, provided with spherical seating, and is automatically lubricated by a small rotary pump.

There are two Wheeler surface condensers of the Admiralty type, one being provided for each steam set. The exhaust pipes are arranged so that either engine can exhaust to either one of the condensers, or if the condensers fail, means are provided for automatically exhausting direct to the atmosphere. An ample supply of water for the condensers is obtained from the canal, that for the boilers being obtained from the town mains.

The Line Along Stourbridge Road.
Postal Telegraphs v. Electric Tramways.

The steam piping, which is arranged in duplicate, is of mild steel, the valves being manufactured by Messrs. Winn and Co., of Birmingham.

The arrangement of the switchboard does not differ materially from that usually adopted in American practice; it is split up into panels, which are known as the main station, generator, feeder, and Board of Trade panels. The main station panel is fitted with an ammeter, which shows the total output of the plant; and recording volt and watt-meters are placed on the same board. The generator panels are each fitted with an automatic circuit breaker of the General Electric type, an ammeter, shunt regulating switch, and plug board for station voltmeters.

View of Line.

The feeder panels are also provided with an automatic circuit breaker and lightning arrester. The inevitable Board of Trade panel contains all the instruments necessary to comply with the Board of Trade regulations.

The Track Construction.

The line is single track throughout. The gauge is 3 feet 6 inches, and constructed throughout with girder rails weighing 75 lbs. to the yard. In the borough of Kidderminster the track is laid upon a bed of concrete 6 inches in thickness, and for 18 inches on either side of the track it is paved with 3 inches × 5 inches Clee Hill granite setts. Along the Stourport Road to the level crossing of the Great Western Railway the line, with the exception of one short length, is laid along the northerly side of the road, the rails being laid on sleepers, the space between the rails and on each side being made up with macadam. The return is entirely by the rails which are bonded with Chicago bonds.

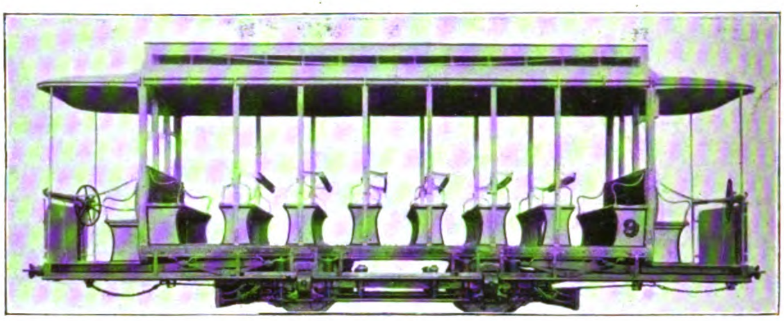
This line is probably the first instance in this country of a tramway passing over the level crossing of a railway, and it is hardly necessary to say that a satisfactory means of doing this has necessitated much care. It was imperative that the tramlines should be broken where they intersected the railway, and to keep up the continuity of the return circuit of the tramway entailed carrying heavy copper connections from one side of the crossing to the other.

It generally follows that the introduction of an electric tramway system into a district brings certain road improvements in its train, nor has the Kidderminster line proved any exception to the rule, for the system has entailed very considerable road alterations along the route. The line runs mostly at one side of the road, and as a clear carriage-way had to be left for the ordinary traffic, it necessitated widening the roadway in many places, but, what was more serious, it involved the widening of three bridges. One of them being a double bridge spanning both the River Stour and the Worcestershire Canal, presented considerable difficulty, for the sides of the original bridge did not run straight, but in a double "S" bend, and to make matters worse, the arch spanning the canal was skewed. This bridge has been widened on both sides and made straight throughout its entire length of about 180 feet. The arch spanning the river was widened on both sides by building brick arches alongside, the new work being tied in to the old by means of tie-bolts carried right through from side to side. The skew arch could not be widened in the same manner, owing to the peculiar shape of the old bridge, and necessitated steel girder construction, the longest span being 38 feet 6 inches.

The Overhead Work.

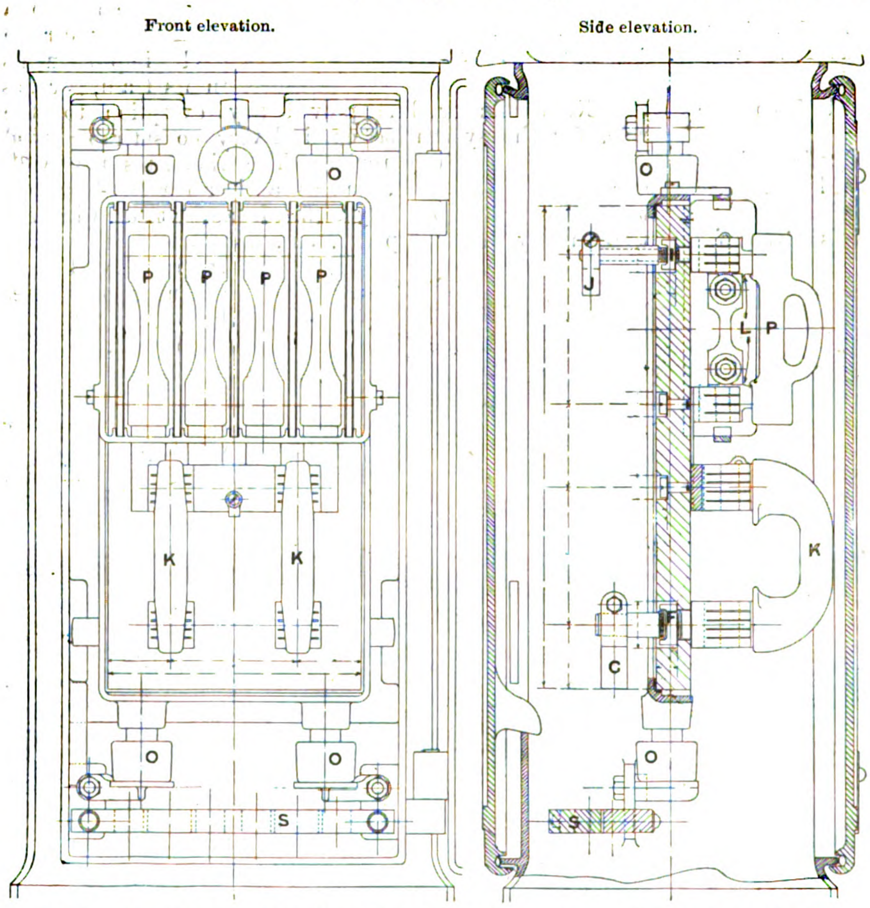
Owing to various obstacles, it has been necessary in no less than three instances to place the poles on opposite sides of the road; that is, the poles and wires for some considerable distance are on one side of the road only, and then for some distance on the other side of the road, when they again cross, so that the system provides excellent examples of the adaptability of the Dickinson side trolley with regard to the wire, for it must be remembered that the track cannot follow the variations that have been rendered necessary in the position of the overhead wire.

The overhead wire is suspended from tapered steel poles, 6 inches and 7 inches diameter, which are fixed at an average distance apart of 50 yards. They stand 22 feet above the ground, and are bedded in concrete to a depth of 6 inches below the surface of the road. Two trolley wires are provided, one for up line, and the other for down line working, the necessity for overhead switches at the passing places being thus avoided.



TRAILER.

The height from the rail to the trolley wires is 21 feet. The lengths of the bracket arms from which the trolley wire is suspended vary considerably, the longest being 8 feet 6 inches, and the shortest 2 feet 6 inches, the greater number being of the latter length. The trolley wire is suspended by riveted gun-metal ears, which are in turn suspended from bell insulators fixed to the bracket arms by wrought-iron clips.



G and J, Clamp cable sockets; K, Main switch carrying 400 amperes; O, Oil insulators; P, Section switch; S, Clamp for cables.

HALF-MILE JUNCTION PILLAR.

There are two main feeder cables from the power house, one going east towards Kidderminster, and the other west towards Stourport. As is customary on English lines, at every half mile the trolley wire is divided by section insulators, at which points the feeder boxes are located. These feeder boxes are about 4 feet 8 inches high, and are placed usually near the post supporting the sectional insulators; they contain two main knife switches feeding on to an omnibus bar, from which bar there are four cut-out fuses, which can feed both ways on to the double trolley wire. The feeder switches are shown at K in the detail drawing, and are capable of carrying 400 amperes, while the section switches are shown at P, and are designed to carry 50 amperes. Any section can thus be easily disconnected for testing, &c. The main cables are somewhat heavy on account of the considerable distance traversed. It has to be remembered that the power house is practically at one end of the system, which is, of course, dictated by convenience and economy. The east-going feeder is a 19/14 stranded cable, and extends to within half a mile of the Kidderminster end. The west-going feeder consists of a 37/11 cable as far as the third feeder box, from which point, and on as far as the next two boxes, it is reduced to 37/12, and from thence to the last feeder box it is reduced again to 19/14, finishing up within half a mile of the terminus. A 7/22 cable is connected to the rails at the extreme ends, and brought back to the switchboard for testing the drop in the return circuit.

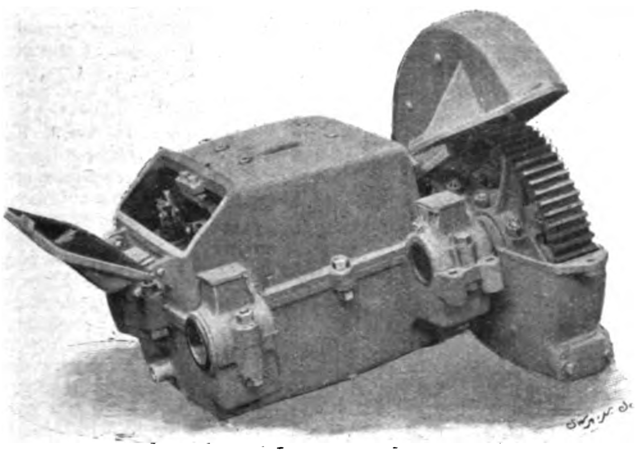
The feeder cables, which are of the Diatrine type made by Messrs. Glover & Co., are lead sheathed and armoured; they are buried in the ground at a depth of 18 inches.

It will be noticed from the illustrations that the cars differ from the usual English practice, in that they are not provided with outside seats, and they are furnished at each end with vestibules. There are 10 in all, six of the closed type with motors 27 feet 6 inches in length over all and 6 feet 4 inches in breadth. These have a carrying capacity of 24 passengers; in addition there are three open trailer cars with a carrying capacity of 40 passengers.

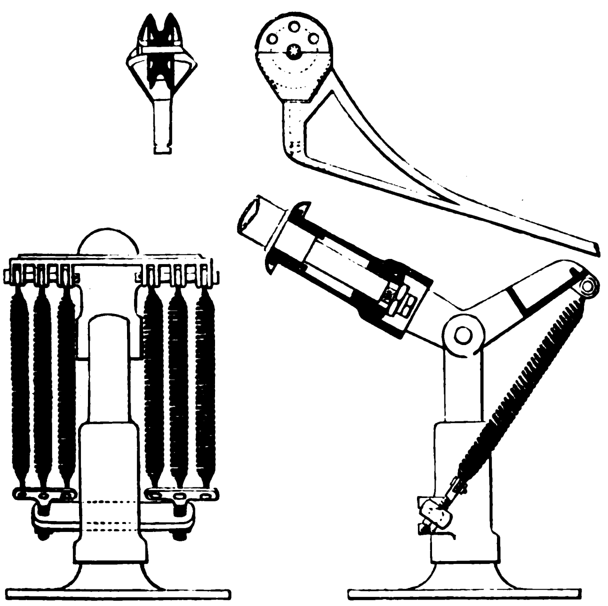
The trucks are of the Brill cantilever type, with a wheel base of 6 feet 5 inches, the wheels being 2 feet 6 inches diameter. The bottom framing of the cars is constructed of teak, the body of teak and English ash, and the panels of Honduras mahogany. Each motor car is equipped with two 15-B.H.P. four-pole motors of the ironclad type, with spring suspension and geared to the axles with spur gearing having a ratio of 4 to 1. The armatures are of the drum type, slot wound with counterpart renewable coils. The armatures are cross connected, so as to have only two points of commutation, carbon brushes being employed.

The controllers, one of which is fixed at each end of the car, are of the series parallel type, one controller handle being supplied with each pair of controllers, which are so arranged that it is impossible to detach it, excepting when the controller is in the "off" position. Each car is lighted with 10 16-C.P. incandescent lamps arranged in two circuits of five lamps in series. The interior of the car is lighted by three clusters of lamps, one containing four, and two containing two lamps, and a head light, which also lights the vestibule, arranged at each end over the platform.

The most interesting feature about the car is the trolley pole, which is of the well-known Dickinson type. It will be remembered that this device was first used on the South Staffordshire tramway, and the principle has been since pretty widely adopted on English lines. The chief difference that exists between the Kidderminster and the South Staffordshire trolleys is, that the horizontal springs used at the base of the latter have been replaced by inclined springs. The detail drawings show the arrangements very clearly.



Car Motor and Gearing.



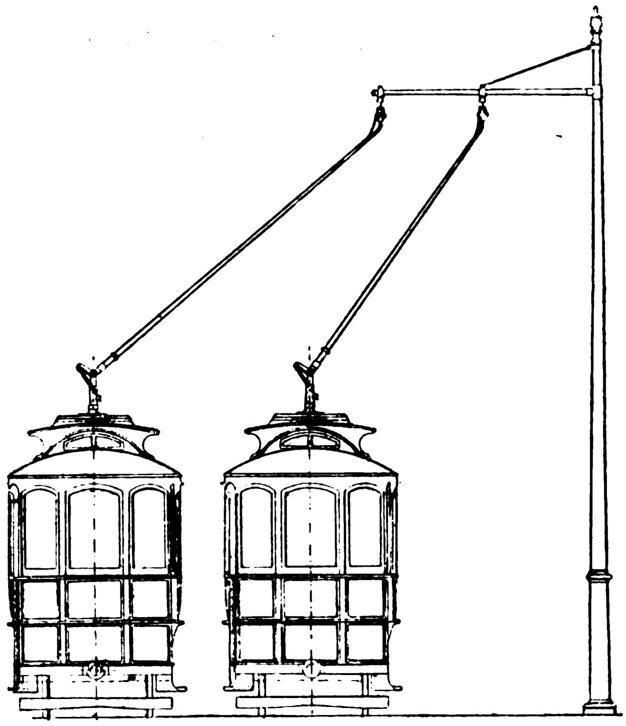
Details of Trolley Pole.

The trolley pole is a light steel tube 15 feet long, tapering from $2\frac{3}{8}$ inches to $\frac{3}{4}$ inch outside diameter, and fitted

the pole forms part of the electrical circuit. Each car is provided with a lightning arrester.

As we have already mentioned, the contractors for the complete electrical installation were the Brush Electrical Engineering Company; the contractor for the permanent, way and buildings was Mr. George Law, Kidderminster Messrs. James Russell & Sons, Limited, Crown Tube Works, Wednesbury, supplying the poles.

Messrs. Alfred Dickinson & Co., 120, Colmore Row, Birmingham, were the consulting engineers for the whole



End Elevation of Two Cars on Line.

undertaking, Mr. G. B. Parlett, A.M.I.C.E., being resident engineer and their representative throughout the work. On behalf of the Brush Company, the work has been carried out by Mr. Geo. Sillar, under the general direction of Mr. R. Dawbarn, superintendent engineer, assisted by Mr. S. Mahood, as resident engineer. We are much indebted to these gentlemen, as well as to the Brush Electrical Company for their assistance in compiling this article

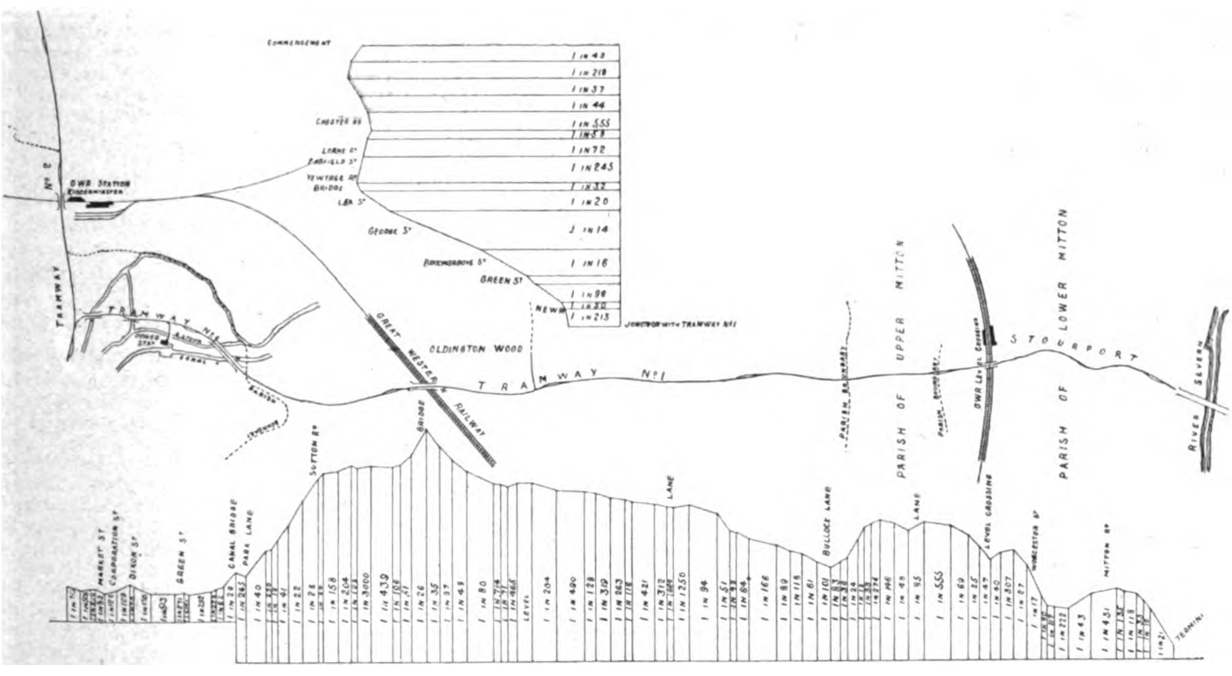


Diagram of Kidderminster and Stourbridge Tramway.

with swivel head, so as to allow the wheel to turn and adapt itself to any position of the trolley wire. The base of the trolley pole is supported on four insulators, as the whole of

National Telephone Company.—It is stated that Mr. Faithfull Begg is named as the successor to Sir James Ferguson on the board of this company.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

(*Concluded from page* 692.)

Bradford.—The Tramways Committee has now given up all hope of the possibility of the Bolton Road being ready for Whitsuntide.

Chesterfield.—The question of the adoption of electrical tramway traction is at the present time occupying the attention of the Corporation. There exists a tramline in the borough about a mile in length, but the extension of the system is under consideration, and as the hilly nature of the district renders horse traction both expensive and inadvisable the "city fathers" are considering the best substitute. The matter was ventilated at a meeting of the Council last week, when the matter of mechanical traction was mentioned. The following resolution was passed:—"That this Corporation recognise the advisability of applying mechanical traction on the present tramways, and that it be an instruction to the Tramways' Committee to have estimates prepared for the work and present to the Council at the next monthly meeting, bearing in mind any subsequent additions, and the necessity of providing workmen's tickets at nominal rates." A special meeting of the Council is to be called to consider the matter in all its bearings. Councillor Markham, in moving the resolution, referred to what is being done in electric traction in other parts of the country. He said that the Corporation had now the Brampton Tramway in their own hands, and it would be an easy matter to demonstrate on that piece of line whether electrical traction would be for the good of the town or not. He himself believed it would add very much to the prosperity of the town and add materially to the value of the land adjacent to the tramways if such a system were adopted. Alderman Wood, in seconding, said that they wanted to consider whether a small scheme to begin with, or enlarging the present tramway, would be a wise thing for the Corporation to entertain. To go into the question of supplying electricity for a tramline only a mile long would be going to enormous cost with very little benefit, and it would be much easier for the committee to report on a tramway double or treble that length.

City and Brixton Railway.—The City and Brixton Railway Bill, which has already been sanctioned by the House of Commons, has been referred to the Unopposed Bill Committee of the House of Lords, owing to the withdrawal of the threatened opposition. By this Bill, which will now in due course receive the Royal assent, a new company will be incorporated with a share and loan capital of £1,600,000 for the purpose of constructing an electric railway from Brixton Hill to a junction with the City and South London Railway at a point under the High Street, Borough. The period sought for the construction of the line is five years from the passing of the Act.

The Electric Power Schemes.—The Nottingham Chamber of Commerce on Monday resolved to support the Bill of the General Power Distributing Company now before Parliament.

Halifax.—The Tramways Committee made a trial trip on one of the electric cars on Tuesday. It is expected that the cars will commence running on June 9th.

Leeds.—The Highways Committee, on 11th inst., confirmed the recommendations of the management committee to extend the electric tramway system along Dewsbury Road and on the Headingley and Chapeltown routes. The city engineer (Mr. Hewson) reported that the city accountant's estimate respecting the cost of the electric tramways on the Kirkstall-Roundhay section had proved accurate, notwithstanding certain statements which had been made to the contrary. Mr. Derry's estimate per car mile was as follows:—For repairs, $5\frac{3}{4}$d.; renewals, $1\frac{1}{10}$d.; interest and sinking fund, $2\frac{1}{4}$d.; total, 9d. The actual expenditure had been $8\frac{7}{10}$d. per car mile.

Llandudno.—Mr. Preece has been consulted by the Electric Lighting Committee upon what system of traction they should insist upon with the Light Railway Syndicate. In his report Mr. Preece strongly advises the overhead system.

The Metropolitan District Railway and Electric Traction.—The shareholders of the Metropolitan District Railway Company had before them on Tuesday the Bills which are being promoted by their company. One of these is applying for further powers to the Metropolitan and Metropolitan District Railway for the ventilation of the railway, and in relation to the working of their undertakings by electrical power. Mr. Staats Forbes, in explaining matters, said that the Bill would give them power when the convenient time came, and the method was sufficiently developed, to apply certain funds of the company for the purpose of working by electricity the railways of the Inner Circle. The Metropolitan Company is applying for similar power, and the District Company could not dissociate itself from that company in respect to electrical communication. They were bound to work in harmony. One of the clauses in the Bill empowered the Metropolitan and District Companies to enter into agreements as to working of traffic by and supply of electrical power. Of course, the adoption of electricity was a matter they could not go into with absolute indifference as to the question of cost. A good deal, however, was now known about this form of traction. It had its advantages and its disadvantages; but the proprietors decided as far back as February last year that it was a matter they ought to be prepared to face at the right moment. Their idea was that £500,000 would be extremely well spent in adapting their railway to electrical traction over that particular part of it which he had mentioned, which was crowded with traffic, and so much of which was incapable of anything but very imperfect ventilation. They were instructed by very eminent authorities that the financial burden cast on the two companies would be extremely moderate in comparison with the great advantages to be secured not only by getting rid of many of the offensive qualities of the air in the tunnels, but also in the saving in the cost of traction, which they were advised would be considerable. The matter was one demanding some care, and they, naturally, wished to be in the hands of perfectly responsible engineers of eminence. In Sir J. Wolfe Barry, a man of considerable experience, who had advised the company almost from its inception, and Mr. Preece, the electrician of the Post Office, and one of the most distinguished members of his profession, they had thought well to vest the preliminary inquiries. Those gentlemen were now concerned in the matter, and the directors would not proceed until they were assured by the report and recommendations of those gentlemen that it was safe to do so. They were gradually gaining experience in the matter of electrical traction. The greatest enterprise of the kind yet approaching to anything like development was the Central London Railway. They knew a little about the question from what had been done on the City and South London line and the Liverpool Overhead Railway, but the Central London Railway, which would be running by the end of this year or the beginning of next year, would doubtless open their eyes to a good many things. The experience of that company would be very useful to the District and Metropolitan Companies. The Chairman then moved the approval of the Bill in so far as it affected the company.

Newcastle.—The lease of the Newcastle Tramways to a private company is rapidly running out, but the new committee of the Corporation is now moving in the direction of a complete scheme, and on Monday agreed to appoint as specialists, to prepare a full report, Dr. Hopkinson, to advise as to the electric system; and Mr. Colamb, C.E., of Edinburgh, to do the same in respect to cable tramways.

Nottingham.—It is stated that a special meeting of the whole Council in committee was held on Monday for the purpose of considering in detail the report of the Tramways Committee, which was presented to the Council on April 4th last, and was discussed a second time on May 2nd. After an exhaustive debate the report, slightly altered, was adopted. There were two dissentients; one objected to the position of the proposed tram centre in the Great Market Place, and the other was opposed to the overhead electric system; he preferred the cable system. The Council instructed the Tramways Committee to include in the Bill to be presented to Parliament several sites for the power stations in connection with the tramway system, in addition to the site originally agreed upon. At the same meeting the Council considered the Bill now being presented in Parliament by the General Power Distributing Company. The meeting authorised the Electrical Energy Committee to reduce the charges for the supply of electrical energy in the city, and also to extend the electrical undertaking all over Nottingham, both for lighting purposes and for power.

Penarth.—The Penarth Light Railway inquiry will probably take place at Cardiff on June 2nd. The opponents include the Cardiff Corporation and the Taff and Barry Railways.

Richmond.—"A Resident of Richmond" writes to the *Times* railing at the promoters of the proposed light railway over Richmond Hill, and flinging the invective at the overhead trolley system in the same old-fashioned way adopted in bygone days in the country. He says it is unfortunate that the promoters have not to apply to Parliament for powers. "All that is necessary for the London United Tramways' Company, Limited (the promoters of the scheme), being to obtain an order from the triumvirate composing the Light Railway Commission, and the approval of the Board of Trade." He adds, "It need hardly be pointed out how a lofty line of gibbet-like supports for the wire which conveys the electricity will interfere with the natural beauty of the neighbourhood, and it is sad to think of the sylvan glades of Petersham Common—perhaps unequalled in wild picturesqueness within so short a distance of London—being desecrated by the vulgar if useful tramcar and its iron way."

Southport.—The Town Council has an electric tramway scheme in view, for it has resolved to widen the esplanade from the promenade to the Birkdale boundary, and form a shrubbery as a preliminary to a future electric tramway round the Marine Drive.

Sunderland.—At the Town Council meeting last week Mr. Crown moved the rescinding of a minute recommended by the Tramways Committee, and passed at the last meeting by the Council, appointing a deputation of six members and the electrical engineer to visit a number of towns for the purpose of gaining information with respect to electrical traction as applied to tramways, for the benefit of the Corporation who are considering a scheme for the application of electric traction to, and for the aquisition of, the tramways of the borough. Mr. Crown said he had learned that the deputation had drawn up a programme to visit the Continent as well as towns in England. They were going to start at Newcastle, and go from there to Hamburg, from Hamburg to Berlin, from Berlin to Brussels, and Brussels to Paris, and from Paris to London and the English large towns. He thought there was no need for seven gentlemen to go any such distance and spend any such amount of the ratepayers' money, and he hoped that the majority of the Council would come to that conclusion. Of course, the gentlemen could go to St. Petersburg and New York, and Philadelphia if they liked, but what he did object to was to them going at the ratepayers' expense. There were ample opportunities at Hamburg to see all that was desired, and this was a cheap place to go to. There were also West

Hartlepool, Leeds, and Sheffield, towns all well supplied with electric traction, and he therefore moved that the minute be rescinded. Alderman Fairless seconded, and said he did not object to the deputation, but he thought the number was excessive. After discussion, Mr. Crown replied, and said the arguments for the deputation were fallacious. There was no amendment, and the motion was then put, and carried by 26 votes to 20.

Swansea.—The British Electric Traction Company, who have taken over the Swansea Tramway system have appointed Mr. Daniel Sugrue, late manager of the Swansea system, to be their district superintendent for South Wales, and have appointed him to a seat on the board. It is anticipated that the work of re-laying the lines will commence in a week or so.

The Telephone Service.—According to the *Daily Chronicle*, it is proposed to hold a conference of representatives of local authorities on the subject of the telephone system, in view of the appointment of a Select Committee of the House of Commons to inquire whether the telephone service should be undertaken by municipal and other local bodies. The Highways Committee have invited the local authorities of London to appoint representatives to attend at the County Hall on Thursday, May 26th, to confer with them as to the needs of London as regards the telephone service, and as to what suggestions should be offered to the Select Committee with reference thereto.

Mr. Hanbury has been appointed chairman of the Parliamentary Telephone Committee, which is to meet on Tuesdays and Thursdays to take evidence, the first witnesses being officials from St. Martin's-le-Grand. A strong effort will be made to expedite matters, so that the committee may be in a position to report to the House before the end of the present Session.

The "Tutanekai."—An Auckland, N.Z., paper says that Mr. W. C. Smythe, of the Telegraph Department in Wellington, is to accompany the *Tutanekai* during her cable-laying operations, as electrician. Mr. C. May, of Dunedin, left for Wakapuaka at the end of March for the work of laying the new cable across Cook Strait, and subsequently to pick up, repair, and relay the present one. This work was estimated to occupy several months.

The War and the Cables.—The *Standard* special correspondent at Key West says that on Saturday last the cutter *Windom* landed there the six men who were wounded while engaged in the risky operation of cutting the cable off Cienfuegos on Wednesday. Four boatloads of men were sent from the ships to Colorado Point, at the entrance to the harbour, furnished with grapplers for the purpose of hauling up and severing the cable. As they approached the shore a detachment of Spanish infantry opened fire from rifle-pits, assisted from time to time by a machine-gun. The warships at once shelled the pits, and drove most of the Spaniards, it is believed, into the lighthouse. Altogether 175 shots were fired from the men-of-war. The boats' crews suffered rather heavily. The operation of cutting the cable was carried out successfully, and Havana is consequently cut off from Cienfuegos, and Cienfuegos from Santiago, while the junction with the British cable from Jamaica to Halifax, which was previously possible, is now destroyed. Marshal Blanco is also isolated from Madrid and the Western portion of Cuba.

A Washington despatch says that the United States Government proposes to sever all the southern cables from Cuba and to leave only the one from Key West to Havana, which it controls. The reason that the Cienfuegos cables were not cut before is that several Americans and other foreigners were still in that town; but now they have all safely reached Port au Prince.

It is stated that the British cable between St. Lucia and St. Vincent has been cut by the Spaniards in furtherance of their designs against the *Oregon*, the *Marietta*, and the *Buffalo*, now off the mouth of the Amazon. These vessels are thus placed beyond the reach of orders or information from the United States, except such as reach the telegraph points, *viâ* steamer, across the severed loop of the cable. That Spain shall get no further telegraphic information is being assured by a stricter censorship, especially over the French line from New York, which has been induced to give a written acceptance of the rules imposed upon it, under the penalty, if found in default, of an instant cutting of the company's cable at Coney Island.

CONTRACTS OPEN AND CLOSED.

OPEN.

Belgium.—May 25th. The date for the receipt of tenders for the electric lighting plant at the railway station at Ghent (Gand-Sud) for the Belgian State Railway Authorities has been fixed for May 25th.

Belgium.—May 31st. The Municipal Authorities of Ixelles, a suburb of Brussels, are inviting tenders until May 31st for the exclusive concession for the supply of electrical energy for lighting and power purposes during a period of 26 years, that is, to September 1st, 1924. Tenders to be sent to the Secretariat de la Commune d'Ixelles, Brussels, from whence particulars may be obtained.

Bury St. Edmunds.—June 13th. The Corporation invites tenders for the supply and erection of Lancashire boilers, three 60-kw. steam dynamos, transformer and booster, accumulators, street mains, and various other machinery and apparatus for the electricity undertaking. Consulting engineer, Mr. F. H. Medhurst, 13, Victoria Street, S.W. See our "Official Notices" May 13th.

Coventry.—June 7th. The Electric Lighting Committee invites tenders for electric mains, switchboards, arc lamps, posts and apparatus in connection therewith. For particulars of the several sections see our "Official Notices" May 13th. Mr. Gilbert S. Ram, city electrical engineer.

Dublin.—May 23rd. The Corporation wants tenders for the supply of high tension feeders and low tension distributors laid and jointed complete on a solid system, not including road work, but including the connecting up of existing consumers to the new mains. Also for transformers (20 to 50 kw., about 700 kw. in all) with instruments and apparatus in sub-stations erected and fitted complete. Particulars at the office of the city engineer; or from Prof. Kennedy, 17, Victoria Street, S.W. See our "Official Notices" May 6th for particulars.

Glasgow.—May 21st. The Corporation is inviting tenders for the excavator and concrete works of the new generating station to be erected at Port Dundas. Architect, Mr. A. Myles, 143, West Regent Street, Glasgow.

Hammersmith.—June 8th. The Vestry is inviting tenders for the supply and erection of a Ledward evaporative condenser and tanks, air pump, circulating pumps, and pipe work. Consulting engineer, Mr. A. H. Preece. See our "Official Notices" for particulars.

London.—June 21st. The London County Council is inviting tenders for engines, dynamos, accumulators, switchboards, feeders, distributors, and service mains and all accessories, to be fixed complete in buildings at the Crossness Outfall Works, near Erith, Kent. The L.C.C. also requires tenders for providing and fixing cables, wires, conductors, casing, pendants, brackets, and other fittings, columns, lanterns, lamps, switches, and switchboards, distributing boards, fuses, cut-outs, &c., necessary for the lighting by electricity of the Crossness pumping station and works, near Erith, Kent. Particulars of both contracts from the Engineer's Department, County Hall, Spring Gardens, S.W. See also our "Official Notices" this week.

Russia.—May 27th. Tenders are being invited by the Municipal Authorities of Odessa for the concession for the construction and working of three lines of electric tramways in the town, the total length being about 39 versts. Particulars may be obtained from La Mairie d'Odessa, Russia, to whom tenders are to be sent.

Southampton.—May 23rd. The Corporation is inviting tenders for the necessary trenching and laying of conduits for electric mains in various thoroughfares. Particulars from the Town Clerk, Municipal Offices.

Spain.—May 28th. Tenders are being invited by the Municipal Authorities of Plencia (province of Vizcaya) for the concession for the electric lighting of the public streets of the town. Tenders to be sent to El Secretario del Ayuntamiento de Plencia (Vizcaya) from whom particulars can be obtained.

Sunderland.—May 27th. The Corporation invites tenders for the supply of steam and other piping, and water softener for the electricity works. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" May 13th for particulars.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

Aberdeen.—The Gas and Electric Light Committee last week considered the tenders sent in for laying the necessary cables for the extension to the harbour and the West End. The offers sent in were as follows:—The Western Electric Company, £14,318; W. T. Glover & Co., £13,113; Callender's Cable Company, £12,642; British Insulated Wire Company, £12,405; and Messrs. Siemens Bros., £12,138. The Messrs. Siemens' offer, being the lowest, was accepted. Powers are to be applied for to borrow an additional £20,000.

Bethnal Green.—On Tuesday, at the meeting of the Bethnal Green Guardians, the following tenders were received for the installation of the electric system in their new infirmary, which will be the most complete in the metropolis:—Messrs. Speedy & Co., £6,659; Cox Walkers, £9,920; W. B. Scott & Co., £8,671 8s. 5d.; G. E. Cockburn, £8,741; Sharp & Piper, £6,460; Thames Ironworks Company, £9,321; Paterson & Cooper, £6,992; Nicholson & Tyler, £7,921 6s. 7d.; H. F. Joel & Co., £7,920 14s.; Private Wire and Telephone Installation Company, £8,919; Calvert & Co., £4,965; National Electric Free Wiring Company, £7,631; Richmond Engineering Works, £5,840 10s.; H. C. Keen & Co., £7,775; Cash, Robinson & Co., £8,100: Crompton & Co., £8,223; Laing, Wharton and Down, £7,272; Hampton & Sons, £6,837; H. J. Rogers & Co., £7,125; Troup, Curtis & Co., £7,192; Brush Electrical Engineering Company, £6,958 10s. The tender of Messrs. Calvert & Co., the lowness of which was freely commented upon, was unanimously accepted. Messrs. Giles & Gough, of Charing Cross, are the architects.

Bootle.—Last week on the recommendation of the Watch Committee, the following tender of the British Insulated Wire Company, Limited, Prescot, was accepted in accordance with the specification prepared by Mr. T. L. Miller, electrical engineer for the borough:—65 10-ampere arc lamps with lamp-posts, incandescent lamp brackets, lamps, and other accessories, at £25 5s. 3d. per lamp; and seven 10-ampere arc lamps, with suspending wires and other accessories, at £19 18s. 9d. per lamp.

Colwyn Bay.—The District Council last week accepted the tender of Mr. Bertram Thomas for £1,469 for electric lighting on the parade. The following is a list of the tenders sent in, reproduced from the *Contract Journal*:—

	Gas plant.	Steam plant.
Eckersley & Co., Manchester	£1,971	£2,101
B. Thomas, Manchester (*accepted)	1,469*	1 589
British Insulated Wire Company, Prescot	1,507	1,589
Calvert & Co., Manchester	1,306	1,415
Smith & Co., Southport	1,398	1,418
Siemens Bros. & Co., Westminster	1,723	1,838
Sharp & Piper, Westminster	1,684	1,784
H. J. Mills & Co., Salford	1,684	1,807
Lea, Son & Co., Shrewsbury	1,870	2,008
Laing, Wharton & Down, London	1,661	1,764
Brook, Hirst & Co., Chester	1,510	1,627
Crompton & Co., Limited, London	1,685	1,707
Donnison, Barber & Co., Manchester	1,530	1,611
J. Maxwell & Sons, Dundee	1,490	1,584
J. Lomax, Kendall & Co., Manchester	1,769	1,864
G. Hill & Co., Manchester	1,522	1,654
Rhodes, Webster & Co., Bradford	1,481	1,591
Wallsall Electric Company, Wallsall	1,545	1,648
Belshaw & Co., Chester	1,904	2,084
W. Lucy & Co., Oxford	1,472	1,699
Donnison, Berlyn & Co., Liverpool	1,474	1,599
Lightfoot Bros., Manchester	1,425	1,541
J. Haynes & Co., Limited, Liverpool	1,577	1,751

France.—The French Post and Telegraph Authorities have just divided a contract for 139 kilometres of electric cables between the three following firms:—Messrs. De la Malrie & Co., of Gravelles-St. Maurice (Seine); the India-Rubber and Gutta-Percha Company, of Persan Beaumont; and M. A. Grammont, of Port de Cheruy.

London.—The London County Council Asylums Committee reported on Tuesday having accepted at £16,665 the tender of Edmundson's Electricity Corporation, Limited, of Westminster, for the electric lighting of the Heath Asylum, Bexley.

London.—The Private Wire and Telephone Installation Company have received orders from the Metropolitan Asylums Board to supply and fit an installation of telephones, fire alarms, and electric bells at the Grove Hospital, Tooting; and telephones at the North Eastern Fever Hospital, Tottenham. The same company has also instructions to fit the New County Hospital at Wakefield with telephones, electric clocks, and electric bells, for the West Riding County Council of Yorkshire.

Shoreditch.—At the meeting on Tuesday evening the Vestry considered the following tenders for the supply of cables for the arc light extension:—Messrs. W. T. Glover & Co.; Messrs. Siemens Bros.; Henley's Telegraph Works, Limited; The British Insulated Wire Company, Limited; Callender's Cable Company, Limited; The Western Electric Company, Limited; and Messrs. Witting Bros., Limited. The tender of Messrs. Glover & Co., for supplying cable under a five years' guarantee, was accepted at the following rates:—

		Including laying and jointing. s. d.	Delivery only. s. d.
·023	High tension twin cable	1 6 per yard	1 8
1·0	Low " "	10 1 "	9 9
·75	" " "	7 11 "	7 7
·5	" " "	5 4 "	5 1
·33	" " "	3 9½ "	3 6½
·25	" " "	3 1 "	2 10
·16	" " "	2 2 "	1 11

The Vestry also considered the following tenders for the supply of arc lamps and fittings:—

	£	s.
Messrs. Oliver & Co.	1,968	8
The Brockie-Pell Arc Lamp Company	2,046	0
Messrs. Johnson & Phillips	2,053	18
Messrs. Crompton & Co.	2,110	0
Messrs. Lucy & Co.	2,331	0
Messrs. Bergtheil & Young	2 382	0
Blahnik Arc Lamp Company (exclusive of carriers)	1 570	0

The tender of the Brockie-Pell Arc Lamp Company was accepted. The Vestry received the following tenders for supplying and fixing an electrically driven fan in the engine room:—

	£	s.	d.
Messrs. Pickup & Co.	69		0
The Blackman Ventilating Company	80	10	0

The tender of the Blackman Company was accepted.

Walsall.—The Electric Lighting Committee has accepted the tender of Messrs. Thomas Parker, Limited, to supply and erect an additional transformer for £558.

Waterloo.—The Council has given the contract to Messrs. Waring & Gillow, Limited, of Liverpool, for an electric light installation at the Town Hall.

FORTHCOMING EVENTS.

1898.

Friday, May 20th, at 10.30 a.m.—Second day of the Federated Institution of Mining Engineers at Burlington House, Piccadilly. Paper by Mr. W. T. Goolden, on "Coal Cutting by Machinery." Mr. W. Dixon's paper on the "Latest Developments and the Practical Application of Alternating Multiphase Machinery for Electric Power Transmission" will be open for discussion.

Saturday, May 21st, at 11 a.m.—Institution of Electrical Engineers. Students' visit to the works of the Electric Welding Company. Applications to join the party should be made at once to the Students' Hon. Sec.

Monday, May 23rd, at 8 p.m.—Society of Arts. Fourth and final Cantor lecture on "Electric Traction," by Prof. Carus Wilson:—Case when the final speed is not given—Design for covering a given distance in the shortest time for a given current—Time curves—Effect of using driving-wheels of different diameters — Design for covering a given distance in a given time, with the least possible expenditure of energy—Influence of the weight of the motor on the economy—Advantage of gearing—Example—The Chicago Metropolitan Elevated Railroad.

Wednesday, May 25th, at 7.30 p.m.—Institution of Civil Engineers. Students' Annual Dinner, Sir Douglas Fox in the chair, Restaurant Frascati.

Thursday, May 26th, at 9 p.m.—Conversazione at the Institution of Civil Engineers.

At 8 p.m.—The Institution of Electrical Engineers at the Society of Arts, John Street, Adelphi, W.C. "The Design of Electric Railway Motors for Rapid Acceleration," by Prof. Charles A. Carus-Wilson, member.

Friday, May 27th, at 5 p.m.—Physical Society, Burlington House. Agenda, "A Simple Interference Method of Reducing Prismatic Spectra," by Mr. E. Edser and Mr. Butler. "Some further Experiments on the Circulation of the Residual Gaseous Matter in Crookes Tubes," by Mr. Campbell Swinton.

At 9 p.m.—Conversazione at the Institution of Civil Engineers.

NOTES.

Presentation.—The employés of the Edison and Swan U.E.L. Company, Limited, and Altrincham Electric Supply, Limited, were entertained on Thursday evening at supper by Mr. Cowan, their late manager, and Mr. Still, who has been associated with him for many years, on the occasion of their leaving the firm. The gathering was a great success, and the men, having drunk prosperity to the Edison-Swan Company, presented Mr. Cowan with a handsome silver bowl, and Mr. Still with a massive cigarette box, both suitably inscribed. The presentation was made by Mr. Fawcus, director of the company, on behalf of the men, who all very heartily wished Messrs. Cowan & Still every success in their new venture as manufacturers of electrical specialities.

Appointments.—Mr. E. Garcke, managing director of the British Electric Traction Company, Limited, informs us that the following staff appointments have been confirmed by the board of directors :—

Mr. George Stevens (late town clerk of Hyde).	has been	appointed	Secretary
Mr. C. H. Dade	"	"	Assistant secretary.
Mr. G. Walmsley (late secretary of the company)	"	"	Accountant.
Mr. Stephen Sellon, Assoc.M.Inst.C.E.	"	"	Parliamentary engineer.
Mr. C. H. Gadsby, Wh.Sc., M.I.E.E.	"	"	Contract engineer.
Mr W. Howard Smith (late engineer on the construction of Lynton and Barnstaple Railway, and formerly city engineer, Carlisle)	"	"	Permanent way engineer.
Mr. H. M. Sayers (late engineer to Madrid, Oporto, and Bournemouth Electric Light Stations)	"	"	Power engineer.
Mr. T. B. Goodyer (late traffic manager of Birmingham Tramways)	"	"	General traffic superintendent.
Mr. J. A. Lycett (late clerk to the Kingswinford Rural District Council). Address: Wollaston, Stourbridge	"	"	Superintendent for Birmingham district.
Mr. J. Vincent Kitchener, (formerly secretary of the company). Address: 19, York Place, Oxford Road, Manchester	"	"	Superintendent for Manchester district, including the Potteries.
Mr. D. F. Sugrue (late manager of the Swansea Tramways Company). Address: Tramways Depôt, St. Helens, Swansea	"	"	Superintendent for South Wales District.
Mr. Frank B. Lea ...	"	"	Superintendent for Glasgow district, and *(pro. tem.)* for Newcastle district.
Mr. W. Gumbley, Assoc.M.Inst.C.E.	"	"	Superintendent for Midlands and Eastern Counties district.

Except where otherwise stated, the headquarters of the staff are Donington House, Norfolk Street, Strand, London, W.C.

The Parliamentary Electrical Committee.—Substantial progress was made on Monday, according to the Yorkshire *Daily Post*, by the Joint Committee of the House of Lords and the House of Commons which has been considering the question of electric light generating stations. Considerably more than half the chairman's draft was passed under review, and the main principles upon which electric light companies are to be allowed to work settled. The Committee, in the portion of the report dealt with, hold that the proved public advantages of electrical energy warrant the granting to undertakers of compulsory powers for acquiring sites for generating stations, and lands or easements for mains and pipes and other works. Provision, in their opinion, should be made for the granting of these powers in the provisional orders of the Board of Trade, subject to confirmation by Parliament. Procedure by private bills should be reserved, as at present, for exceptional cases. The powers indicated, it is suggested, may be given either to local authorities or to incorporated companies, whether the incorporation be by special Act or under the Companies Acts. With respect to liability for nuisance the Committee are of opinion that where the site for a generating station is acquired under compulsory powers, and is specified in the provisional order or special Act, the undertakers should not be subjected to any further liability than that which is imposed by the common law in the case of persons exercising statutory powers and duties. On the other hand, where the site for a generating station is acquired by agreement the Committee think the undertakers ought to be subject to the liability imposed by the common law. With respect to notices, they think that the existing practice as to notices to the local authorities, and also to owners, lessees, and occupiers of land, should be followed. As to notices in gazettes and newspapers no amendment of the existing law is suggested. Subject to these observations the Committee are of opinion that compulsory powers for the acquisition of land for a generating station may be properly given where the proposed site is not within the area of supply. The local authorities along the trunk lines, it is suggested, should have the same notices and the same *locus standi* as if that district were within the area of supply. In the case of powers being given for the erection of a generating station outside the area of supply the Committee think that powers may properly be given for laying the mains in streets leading from the generating station to the boundaries of the area of supply. It is also thought that the local authorities should not have a veto against the erection of overhead wires excepting in the case of the London County Council, the City Corporation, and the larger municipalities throughout the country.

A Cable Tramway Condemned.—Colonel Yorke has recently reported to the Board of Trade on the subject of the Cliff Railway at Constitution Hill, and a copy of the report was before the Swansea Council last week. In his report Colonel Yorke described the line, and said that from tests made in his presence he did not consider that the slipper brakes, which would have to be relied upon in case of the cable breaking, could be relied upon to pull up a heavily-loaded car, especially when the rails were wet or greasy. On the other hand, the grip brake, though powerful enough, was not sufficiently rapid in its application, and the speed might increase to a dangerous extent before this brake came into play. There were other features in the tramway to which objection might be taken. The fact that it had been laid as a single line necessitated the use of automatic switches at the crossing place. These switches must necessarily be uncontrolled, and any ignorant or mischievous person or child could push the switches over into the wrong position and cause an accident. Objection is taken to the Y shaped openings running down the hill, and the report continues :—"On looking at the order of 1896, I find that the line is to be laid on an interlacing line, and that the consent of the Board of Trade and of the Corporation is required if any alteration in this method of construction were desired. Had the line been laid as an interlacing line no switches would have been required, and no opening in the conduit such as I have described would have existed. I am unable to find that the Board of Trade have ever been asked to approve of the construction of the tramway as a single line. For this reason and because of the objectionable features inseparable from the use of a single line, and also on account of the insufficient control over the cars (1) by the engine, (2) by the brakes, which form sources of danger not only to passengers by the trams, but to the public using the thoroughfare, I do not consider the line in its present state suitable for public traffic, and I am unable to recommend the Board of trade to grant a certificate to the company."

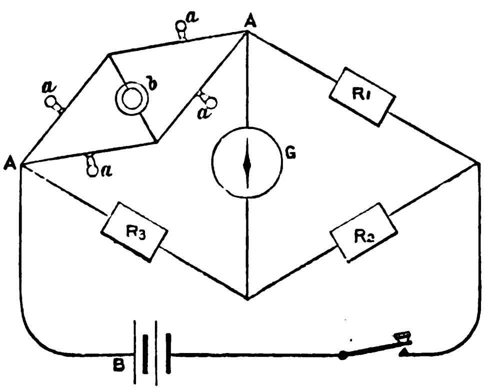
Personal.—Mr. Roland S. Portheim, of Messrs. D. Bruce, Peebles & Co., engineers, Leith, has just concluded a six weeks' tour in the States, where he has inspected many of the electrical manufactories and electrical power installations, more especially those dealing with transmission of power in mills and factories.

We understand that on Thursday last Mr. Henry Wilde, F.R.S., whose name is so well known as that of one of the pioneers in electrical work, was elected an honorary member of the Institution of Electrical Engineers.

Appointment. — We understand that Mr. A. Bentley, A.I.E.E., who went out to South Africa three years ago, has been appointed "electric wiring engineer" to the Johannesburg City Council, at £400 per annum. Mr. Bentley was formerly with Mr. Shoolbred.

Range Finder.—We understand that the Fiske range finder, of which we reproduced a description last week from the *Scientific American*, is made by the Western Electric Company, of Chicago and London.

Measuring the Resistance of Incandescent Lamps.—To those who like unnecessarily complicated ways of electrical testing the method of measuring the resistance of incandescent lamps when lit, described in the *Revue d'Electricité* of March 26th, may be interesting. The authors, MM. Abt and Hoffmann, content neither with taking the ratio of the reading of a voltmeter across the terminals to that of an amperemeter in series with the lamp, nor with a plain bridge test, arranged the test shown in the figure. Four lamps, *a*, *a*, *a*, *a*, are arranged in a quadrilateral



with the battery, *b*, for keeping them alight connected across the diagonal. If the lamps are of equal or proportional resistances, the potentials at A A will be the same. If not, additional resistances are arranged to make the two equal. Then the resistance between A A is measured by connecting R_1 R_2 R_3 to form another quadrilateral with A A and the testing battery, B, and galvanometer, G, connected to complete a Wheatstone's bridge. Then the measured resistance of A A gives the mean of the four lamps, *a*, *a*, *a*, *a*. The whole forms a pretty example of conjugate conductors in a complicated network, and suggests examination problems, but seems poor practice.

The Wright Wave Motor.—An interesting description of the Wright wave motor appears in the New York *Electrical Engineer*. This motor is one of the latest of a long list, which so far has been one of considerable failure. Tests were made in January, 1897, and were encouraging enough to warrant a new wharf and pier extending 350 feet out to sea, and carrying three floats with machinery on the wharf. The floats rise and fall with the waves, and operate vertical hydraulic compressors, which force water into a large air pressure tank, whence it issues as jets upon Pelton motors driving dynamos. The water is simply used over and over again. The tank acts as an equaliser from wave to wave. The present small plant has been running an electric generator continuously since September last, and when enlarged, a transmission line will be built to Redondo, four miles distant, and not far from Los Angeles. A table is given of the results of a public test, extending from December 1st to 11th. The number of waves per minute varied between 3 and 8 on the different days, according to the weather, averaging about 5½. The piston travel varied from 12½ to 18½ feet per minute, both the extremes being, on stormy days, averaging 15½. The average daily tank pressure varied between 150 and 195 lbs., and each float discharged an average of 3·9 cubic feet per minute, and 2·1 H.P. at the Pelton wheel. These figures represent a fall of about 24 gallons of water through a height of 370 feet. The result was nine electric lights kept going. The apparatus is self-regulating to a very large extent, any excessive air pressure tending to counteract the float movement. There is thus steady and continuous working within the limits of the plant.

New Fellows of the Royal Society.—Among the candidates selected by the Council of the Royal Society we observe the name of the Hon. C. A. Parsons, for his invention of the compound steam turbine, which he has adapted successfully to dynamo driving and other uses, and for his recent application of it to marine propulsion. Mr. James Wimshurst is also selected for his electrical influence machines and improvements therein, to which we refer at length on another page.

Corea.—The United States Consul-General at Seoul, Corea, reports as follows, according to *Trade and Industry:* "A company has been formed in the city of Seoul for lighting the streets and residences with electricity, and for operating electric street railroads through the principal thoroughfares. Only the latter will be begun at once. The company, known as the Seoul Electric Company, is composed entirely of Coreans, with the governor of the city as president. They have an exclusive franchise from the Department of Public Works."

Presentation.—Mr. Cassells, late superintendent of mains under the Glasgow Corporation, who has now entered the contracting business, was presented with a handsome testing set by the officials of the electricity department at a smoking concert held a few days ago.

Technical Education.—The Coatbridge Town Council has agreed to give £100 towards the teaching of metallurgy, electricity, &c., in the Technical School, from the local taxation grant, provided a similar sum is given by the County Council.

Correspondence.—Pressure upon our space compels us to hold over until next week a letter from Messrs. Zeitz regarding the "Limerick Electric Tramway Proposal," and one from Mr. E. K. Scott on "Testing Magnet Steel in Bulk."

Appointments Vacant.—The Corporation of Londonderry invites applications for the post of electrical engineer at £160 per annum. See our "Official Notices" this week for particulars.

The St. Pancras Vestry Electricity Committee wants an inspector of works. See our "Official Notices" this week.

The Glasgow Scheme.—We understand that the Corporation on Wednesday approved the minutes of the Electricity Committee, which embodied Mr. Chamen's large extension scheme which we gave briefly a few weeks ago.

The Telephone Committee.—We are compelled, owing to pressure upon our space, to hold over until next week our report of Tuesday's and yesterday's proceedings before the Parliamentary Telephone Committee.

NEW COMPANIES REGISTERED.

British Illuminating Company, Limited (57,260).—Registered May 7th, with capital £50,000 in £1 shares, to adopt an agreement with Smith's Acetylene Gas Lamp and Generator Syndicate, Limited, to manufacture, sell, and deal in calcium carbide acetylene gas generators, and to generate, sell, and deal in acetylene gas, coal gas, and electricity. The subscribers (with one share each) are:—G. Sandeman, Colinton, Midlothian, gas engineer; F. B. Taylor, 25, Mulgrave Terrace, Gateshead, accountant; P. Gilham, 27, Edward's Road, Whitley, Northumberland; J. A. Rowell, 10, Chester Crescent, Newcastle, agent; J. F. Kelly, 51, Doncaster Road, Newcastle, clerk; G. Robson, 64, Rothbury Terrace, Heaton, Newcastle, engineer; T. E. C. Green, 1, Poppelwell Terrace, Preston, North Shields, agent. The number of directors is not to be less than five nor more than nine. The first are H. Coates, N. Wyld, F. H. Smith, and D. J. Adler; qualification, £100; remuneration as fixed by the company. Registered by Jordan & Sons, Limited, 120, Chancery Lane, E.C.

J. Tylor & Sons, Limited (57,279).—Registered May 10th, with capital £200,000 in £10 shares (10,000 £5 per cent. cumulative preference), to acquire the business of a company of the same name (registered in 1890), to adopt an agreement with the said company and its liquidator, and to carry on the business of mechanical and consulting engineers, sanitary, hydraulic, and electrical engineers and contractors, brass founders, galvanisers, platers, tool makers, boiler makers, millwrights, &c. The subscribers (with one share each) are:—W. H. Tylor, 2, Newgate Street, E.C., engineer; J. G. M. Rumley, 43, Palace Court, W., C.E.; W. B. H. Drayson, 2, Newgate Street, E.C., engineer; P. Bright, 2, Newgate Street, E.C., engineer; J. S. Maples, 2, Newgate Street, E.C., engineer; R. Tylor, 2, Newgate Street, E.C., engineer; W. S. Salter, 2, Newgate Street, E.C., engineer. The number of directors is not to be less than three nor more than five; the first are the first four subscribers. Qualification, £1,000; remuneration, £100 each per annum. Registered by H. & G. Keith, 43, Chancery Lane, W.C.

Automatic Light Controlling Company, Limited (57,287).—Registered May 10th, with capital £10,000 in £1 shares, to adopt a certain agreement, and to manufacture, sell, and deal in apparatus and contrivances connected with electric light or gas, and for controlling and regulating the same. The subscribers are:—J. Gunning, Bournemouth, engineer, 100 shares; J. T. Gascoine, Bournemouth, gentleman, 60 shares; G. H. Rolls, Bournemouth, property agent, 60 shares; C. J. Haydon, Bournemouth, solicitor, 20 shares; Mrs. A. P. Gunning, Bournemouth, 20 shares; E. P. Wills, J.P., Haselwood, Stoke Bishop, Bristol, 100 shares; E. S. Wills, Frankfort Lodge, Clevedon, Somerset, 40 shares. The number of directors is not to be less than three nor more than seven. The first are: J. Gunning, J. T. Gascoine, G. H. Rolls, C. J. Haydon, and E. P. Wills. Qualification, £200; remuneration as fixed by the company. Registered office, Richmond Chambers, Bournemouth.

British Electric Transformer Manufacturing Company, Limited (57,293).—Registered May 10th, with capital of £50,000 in £1 shares, to adopt an agreement with A. F. Berry for the acquisition of certain British and Foreign patents for electric transformers, and to carry on the business of electrical engineers, electricians, electric transformer manufacturers, iron and brass founders, tool makers, mechanical engineers, boiler makers, &c. The subscribers (with one share each) are:—R. S. Bain, 25a, Cockspur Street, S.W., chartered accountant; R. J. Wallis Jones, 6, Hampstead Mansions, N.W., engineer; T. Petersen, 119, Worple Road, Wimbledon, electrical engineer; A. M. Billington, 7, Porchester Gardens, W., electrical engineer; A. F. Berry, 8, Heathcote Street, W.C., electrical engineer; W. A. B. Clarke, 10, Norfolk Street, Strand, solicitor; A. J. Allum, 25, Princes Road, Notting Hill, W., clerk. The number of directors is not to be less than three nor more than five; the subscribers are to appoint the first. Qualification, 500 shares; remuneration, £600 per annum and a percentage of the profits divisible. Registered by W. O. Vizard, 10, Norfolk Street, Strand, W.C.

"Volenites," Limited (57,337). — Registered May 13th, with capital £80,000 in £1 shares, to acquire the secret process and patent rights for the manufacture of "Volenites," to adopt an agreement with H. Bennett, and to manufacture, sell, and deal in oil, guano, volenite, vulcanite, railway sleepers, road and street paving, mats, railway carriage and other wheels, pulley wheels, brake blocks, carriage panels, electrical switchboards, fuse bases, electric bell bases, insulating material, electric motors, &c. The subscribers (with one share each) are: — Lurgan, 21, Lowndes Square, S.W., peer; F. B. Jameson, "The Albany," Piccadilly, gentleman; J. R. Parkington, 6, Devonshire Place, W., major; W. H. Wilson, 36, College Green, Dublin, stockbroker; T. B. C. Hardman, 74, Molesworth Street, Dublin, solicitor; J. K. Rigby, 154, Palmerston Buildings, Old Broad Street, E.C., chartered accountant; H. Fenwick, 95, Vauxhall Bridge Road, S.W., secretary; the number of directors is not to be less than three nor more than seven; the first are, Baron Lurgan, F. B. Jameson, J. R. Parkington, and G. V. Sims. Qualification, £250; remuneration, £200 each per annum, and £250 for the chairman. Registered by H. P. Becher, 26, Bedford Row, W.C.

Drake and Gorham Electric Power and Traction (Pioneer) Syndicate, Limited (57,352).—Registered May 14th, with capital £20,000 in £10 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity and manufacturers of electrical apparatus. The subscribers (with one share each) are:—B. M. Drake, 66, Victoria Street, S.W., electrical engineer; C. Poston, Highfield Stevenage, Herts, gentleman; C. J. Linas, J.P., Warnham Court, Horsham; G. T. Balfour, 2, Cushion Court, Old Broad Street, E.C., stockbroker; G. J. Poston, 10, Throgmorton Avenue, E.C., member Stock Exchange; J. F. Albright, 66, Victoria Street, S.W., civil engineer; A. F. Ashwell, 79, Queen Street, E.C., solicitor. The number of directors is not to be less than five nor more than 15; the first are the first 15 persons who subscribe for 50 shares each; qualification, £500; remuneration as fixed by the company. Registered by Ashwell & Co., 79, Queen Street, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

South London Electric Supply Corporation, Limited (50,392).—This company's return was filed on April 7th, when the whole capital of £325,000 in £5 shares was taken up. £2 per share has been called, and £131,334 received, including sums paid in advance of calls.

Dover Electricity Supply Company, Limited (39,779).—This company's return was filed on April 14th, when 4,860 shares were taken up out of a capital of £50,000 in £5 shares, and paid for in full.

Norwich Electricity Company, Limited (30,694).—This company's return was filed on March 30th, when 4,565 shares were taken up out of a capital of £50,000 in £10 shares, and paid for in full.

Chelsea Electricity Company, Limited (20,468).—This company's return was filed on April 28th. The capital is £200,500 in 34,000 ordinary and 6,000 preference shares of £5, and 500 founders' shares of £1 each, all of which have been taken up. 6,666 ordinary and 500 founders' shares are considered as paid, and the full amount has been called, and £166,670 paid on the rest.

Direct Spanish Telegraph Company, Limited (6,732 C).—This company's annual return was filed on April 27th. The capital is £95,000 in £5 shares (6,000 preference). 12,931 ordinary and 6,000 preference have been taken up, £5 per share has been called, and £94,655 received.

Sheffield Electric Light and Power Company, Limited (36,551).—This company's return was filed on April 12th, when 14,000 shares were taken up out of a capital of £280,000 in £7 shares; 4,000 have been issued with £5 per share considered as paid, £7 per share has been called on 10,000 and £2 per share on 4,000, resulting in the receipt of £78,000.

Guildford Electricity Supply Company, Limited (36,725).—This company's return was filed on April 21st. The capital is £20,000, in 3,900 ordinary shares of £5 each and 500 founders' shares of £1 each. 1,542 ordinary and all the founders' shares have been taken up, the full amount has been called, and £8,210 has been paid.

Windsor Electrical Installation Company, Limited (46,186).—This company's return was filed on April 6th, when 20,000 shares were taken up out of a capital of £25,000 in £1 shares. 450 are considered as paid, and £19,550 has been paid on the others. £1 7s. 6d. has been received in respect of 11 forfeited shares.

Gorseinon Electric Light Company, Limited (39,944).—This company's annual return was filed on April 15th, when the whole capital of £1,000 in £1 shares was taken up. 17s. per share has been called, and £843 15s. has been paid, leaving £6 5s. in arrears.

Oxford Electric Company, Limited (34,685).—This company's annual return was filed on April 9th, when 10,000 shares were taken up out of a capital of £100,000 in £5 shares, and paid for in full.

Ormore Valley Electric Light and Power Company, Limited (34,191).—This company's annual return was filed on April 9th, when 710 shares were taken up out of a capital of £10,000 in £5 shares. £5 per share has been called, and £3,350 received, leaving £197 unpaid.

CITY NOTES.

The New General Traction Company, Limited.

The meeting of this company, which was postponed from the 12th inst., was held at Cannon Street Hotel on Tuesday, Captain Francis Pavy presiding. The following report was taken as read:—

"At the commencement of the year the two Bills in Parliament referred to in last year's report, viz., the Norwich Electric Tramways Act and the Coventry Electric Tramways Act, received the Royal Assent. In connection therewith contracts have been entered into with responsible and competent contractors to construct both the Norwich and Coventry lines, and the work is being proceeded with as rapidly as possible. To enable the company to carry through these undertakings, the additional preference capital of £100,000, sanctioned at the last annual meeting, was created and issued at a small premium, thus permitting the directors to make contracts in exchange for shares and debentures in the Norwich and Coventry Companies, as provided in the Acts. The section of the Coventry Company already open for traffic has shown results exceeding the board's expectations, and the Douglas Southern Company in the Isle of Man, in which this company is interested, has also given satisfactory results. The gross profits of the year, including £1,681 18s. 11d. reserved last year on account of Bills before Parliament and since recovered, amount to £12,874 2s. 11d., to which must be added the sum of £2,982 19s. 1d. brought forward from last year, making a total amount of £15,857 2s. to the credit of profit and loss. The sum of £2,230 14s. 4d., representing the undivided profit of the old company, and brought forward from March, 1896, the board recommend shall be placed to a reserve account. The board has further decided to charge against the revenue of the year one-half of the cost of the issue of the new capital, amounting to £2,122 12s. 9d. This leaves a balance of £13,734 9s. 3d., from which have to be deducted £3,435 10s. 6d. and £52 15s. 9d. on account of general expenses, salaries, directors' fees, rent, travelling expenses, and legal and other charges, leaving £10,246 3s. as the amount of revenue to be dealt with. A dividend at the rate of 6 per cent. on the preference capital, calculated from the dates of payment, amounts to about £6,500, and the directors recommend that this be paid, and the balance carried forward to next year. Electric tramway business in Great Britain is still far behind that of most other countries in Europe and America, but steady progress is going on in the use of this power, and from the numerous projects submitted, and those now under consideration, the board have every reason to look forward to future profitable business."
